GENTLEMEN,—I see in your impression of April 29, under the head of "Weekly Gossip," an abstract of a "report of a select committee of the American Institute of New York, appointed (*by whom?*) to examine the paying-out machinery on board of the U. S. frigate Niagara, and to furnish a report thereon concerning the design and construction thereof." We are pretty well accustomed in this country to pass over brother Jonathan's cormorant propensities without notice; but in this instance the *exparte* decision of this mock committee (who have certainly gone the entire ticket) upon work done in this country, is so glaring in its injustice to those who have borne the burden and heat of the day, that it would not be right to allow the statement which your columns have disseminated through the country to pass uncontradicted. The object of the meeting of the committee has manifestly been to show that Mr. W. E. Everett, of the U. S. navy, who had charge of the engines of the Niagara on her first trip, was the sole inventor and designer of the machinery used for paying-out the Atlantic cable in July and August, 1858. For my own part, I cannot accept this machine as altogether the best for the purpose (indeed, it is clear that it was too heavy for use in very rough weather, since men were employed on board the Agamemnon to keep the wheels moving during the rough weather which she encountered, when her stern dropped so much as to withdraw the strain from the cable), but some parts of it were new, and a great advance upon any machinery of the kind employed before. I believe the facts of the case are as follows:—The original machinery consisted of two machines, either of which could be used for paying-out or for hauling in; one of these had four sheaves, the other two. The "commission of engineers" (Mr. Everett being one of the commission) advised in September, 1857, that certain alterations should be made in the machinery, the bulk of which had been recommended to them by Mr. (now Sir Charles) Bright, the engineer, and one of the original projecters of the Atlantic line. One of their most important recommendations was the use of a form of brake invented by Mr. J. G. Appold, F.R.S., which has been employed for testing the engines of the Royal Agricultural Society for a long time, and which afforded a certain degree of compensation to any inequality of strain. If I am not mistaken, the first suggestion of this brake emanated from Mr. Appold himself, and was concurred in by the committee. The brake used by the Agricultural Society was set up by Mr. Amos at the Gutta Percha Company's works in the City-road, at the request of the Atlantic Company's engineer, and (after some experiments) was determined upon; at this time Mr. Everett was not even in England. No alteration whatever was made in the principle of the brakes finally used, and scarcely any in the details of construction; certainly none of the slightest importance. The machines with two over-hanging sheaves used in the former expedition were fitted with Mr. Appold's brakes at the works of Messrs. Easton and Amos. The chief parts of the machines were adopted without any change, but new sheaves were made with deeper grooves, in accordance with Sir Charles Bright's advice, and his recommendation as to guards to prevent the cable from escaping out of the grooves, scrapers to clean the grooves from the accumulation of tar and other details were carried into effect. As to the *new* parts of the machine—the dynamometer for indicating the strain, and the hand-wheel for removing all pressure immediately, if required—the former was patented by Sir Charles Bright in the previous year, and the latter was proposed by Mr. Amos, who took the greatest interest in the construction of the machinery from first to last, and the initiative in the practical design and carrying out of the wishes of Sir C. Bright, the engineer of the company, Messrs. Penn, Lloyd, and Field, who were good enough to lend their valuable aid to the company in the matter, and Mr. Everett, to whom was confided the experiments upon the materials and lubrication of the brakes recommended by the engineer of the company in September, 1857, and the supervision of the construction of the Niagara's machinery, Mr. Clifford being charged with the superintendence of that for the Agamemnon. Mr. Canning and Mr. Woodhouse, to whom was entrusted the important duty of coiling the cable on board the ships, were also consulted as to the machinery, and I shall be very much surprised if Mr. Everett ventures forth from the cover of this self-appointed committee to say that he designed any part of the machinery in question, or even suggested a single bolt or screw in it.

The fact is, that brother Jonathan has intended to be quite smart about the cable business; and no greater example can be found of English frankness and straightforwardness, as compared with American jealousy and unfairness, than the generous manner in which the engineer-in-chief of the Atlantic Company spoke of his American co-adjutors in his published report, as well as in his speech at the banquet given to him at Dublin, and the omission of all allusion to him in the celebration on the other side when all America went mad about the submersion of the cable in her eagerness to claim the entire thing as her own. I need not remind you of the smallness of the share which Americans really had in the undertaking. Three of the original promoters of the company, Sir Charles Bright, Mr. Brett, and Mr. Whitehouse were Englishmen, one only (Mr. Cyrus Field) being an American. More than three-fourths of the capital was found by British subscriptions; and out of the ships furnished by the two Governments to carry out the enterprise last year, the Agamemnon, the Valorous, the Gorgan, and the Porcupine, were provided by our Government, while the United States Government produced only the Niagara.

Under these circumstances it would be well for our Yankee friends to adopt a rule in the celebrated game of *poker*, to which they are so attached, viz., never to brag without holding a good hand.—I am, gentlemen, your obedient servant, T. B. M.

EXPLOSION OF GUNPOWDER WORKS.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—Your correspondent "Polvora" lacks logic. He starts with a curt dismissal of the chemical question; states that powder manufacturers are not insensible to improvements; begs, but only generally replies to, the question whether in certain departments of gunpowder works improvements have

Digitized by Google

not been made; adds that in consequence of such improvements special works have had a complete immunity from accidents—that "hands" have been reduced as machinery has been employed; twits you with severity of remark, but concludes, forgetful of the antecedents of his letter, with the observation that as the lives of many depend upon this business, blessings will rest upon the discoverer of any means which will prevent the recurrence of accidents.

I can only say, gentlemen, that I, amongst others, thank you for the articles you have written upon this matter, and which, to show their importance, has been so extensively quoted and favourably commented upon by the *Times* and other journals, and trust that "War's Alarms" and a sudden *penchant* amongst the community for gunpowder will not induce you to drop a subject which has left a lasting impression upon thousands, as well as Yours obediently,

ONE WHO FELT THE "BLOW."

SUPERHEATED STEAM.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—Under the above head a very strong article appeared in the *Times* of the 23rd April last past, by which the public would be led to suppose that although other persons have attempted to work superheated steam that all had failed save Messrs. Penn and Son. We being patentees of a method for using superheated steam, which is now working both in the Royal Arsenal at Woolwich as well as in the Woolwich Waterman's Company's Boat Osprey, wrote to the editor of the *Times* as under, but our letter has not appeared in that paper. Knowing your impartiality, we venture to request that you will insert in your paper the following statement:—"Our principle of superheating steam, which is by arched pipes over the fire, has been used in the Royal Arsenal at Woolwich for some time, and we have a report of the saving of fuel to the amount of 30 per cent. It is also used in the Woolwich Waterman's boat "Osprey," running daily between Woolwich and London, and there has not only effected a saving of 33 per cent. in fuel, but shows a clear gain of 11 per cent. in revolutions, and that with less pressure on the boiler. We use our steam in the Osprey heated to 450 degrees, and we are satisfied from our experiments previously made that the most effective heat is from 400 to 450."

We are, Gentlemen, your obedient Servants,

PARSON & PILGRIM.

8 Adelphi Terrace, 4th May, 1859.

SHELLS FOR DEFENDING HILLY COUNTRIES.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

SIR,—When the British army under the Duke of Wellington occupied the Pyrenees, in the latter end of 1813, the different divisions were provided with large shells, of about the size of 32-pounders, for the purpose of allowing them to roll down the hills against an approaching enemy, their fuzes being first lighted. I practically demonstrated my improvement on this old plan, by hooking on my frictional ignitor to the fuze-hole of a wooden model of a 32-pounder, and then allowing the shell to roll down the glacis of the fort where Captain Lamprière, R.E., resides. This shell, on arriving at the end of the attached cord, fired the igniter by the check of its stoppage at the exact distance desired, being about 20 yards. This was done in presence of Captain Lamprière, R.E. Immediately after this Sergeant Sturrock, R.E., fired several of my gossamer blank cartridges from Mr. Leech's ingenious and very efficient breech-loading rifle carbine. About a year ago, I in due order submitted the above-named cartridges for the consideration of the Secretary of State for War, and the official answer I received was, that the cartridges would be tried when practicable. I have heard nothing of them since that distant day.

I am, Sir, your obedient servant,

Rosherville, April 27. JOHN NORTON.

The Society of Arts is beginning to move actively in the preliminary preparations for the "International Exhibition of 1861." They state their views thus:—"It is proposed that the works to be exhibited in 1861, shall be selected for their excellence; that they shall be arranged in classes, and not according to countries; that music and painting shall be included; and that foreigners shall be admitted to contribute on the same conditions as British exhibitors."

NOTICES.

The MECHANICS' MAGAZINE will be sent free by post to all subscribers of £1 1s. 8d., annually, *payable in advance*. Post Office Orders to be made payable to R. A. Brooman, at the Post Office, Fleet Street, London, E.C.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 5d. per line for any number of insertions less than 13; for 13 insertions, 4d. per line; and for 52 insertions, 3d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

Special Arrangements for larger or Serial Advertisements. To ensure insertion, Advertisements must reach the Office by 5 o'clock on Thursday evening each week. None can be received after that time for the ensuing number.

With our Next Number will be Presented

A SPLENDID ENGRAVING OF

THE LIGHT-DRAUGHT STEAMERS FOR THE INDUS,

Built by J. SCOTT RUSSELL, ESQ., *for the Scinde Railway Company.*

This Engraving will comprise a side elevation, a longitudinal section, and a plan on a scale of $\frac{1}{4}$th of an inch to the foot.

NO EXTRA CHARGE.

Our Weekly Gossip.

On Tuesday evening Sir William Armstrong was entertained at a public dinner in the Assembly-rooms, Newcastle-upon-Tyne, in celebration of the honour of knighthood recently conferred upon him by her Majesty the Queen in recognition of his services in inventing the new rifled cannon. In reply to "The Health of Sir William Armstrong," proposed by Sir George Grey, Sir William rose, and after a few introductory remarks, said, that with respect to the gun of which so much had been said, it is absurd to suppose that its general character, which is already known to hundreds of persons, and which is already approximately—although only approximately—described in many publications, can be considered a secret. There is a great deal in detail which will be very difficult to make out, and which must be completely mastered before other nations can make the gun. It had been said two of his guns burst at Shoeburyness; but this, like many other assertions that have been made, is wholly, he said, without foundation. It has displayed extraordinary durability; and, in a long course of trial, none of them have exhibited the slightest indication of wear. Seventy pounders and hundred pounders are soon to be constructed upon the same principles. All the writers who have undertaken to give information upon this gun have spoken of a large screw working in the breech end of the gun, and pressing against a stopper for the purpose of closing the bore when the gun is loaded; "but they all ignore the fact," said Sir William, "of that screw being a hollow screw, or they have misunderstood the purpose of its being so. There can be no secret about a process which is now daily performed; the guns are both sponged and loaded through the hollow screw, and it is a great mistake to say that the charge or shot or sponge can be introduced by the narrow slot or opening which is spoken of as receiving the stopper. This stopper is a very small light piece, widely different to that represented in the fancy portraits which have appeared of this gun. It is chained to the gun to prevent the possibility of being lost by casualty. The carriages, which are arranged for guns intended for naval or garrison purposes, are adapted with a slide—a sloping slide, upon which the gun runs back on being fired, and then slips into its original position by gravity, thus obviating the necessity of employing a large number of men. The projectiles are in all cases made of cast iron, thinly coated with lead. The projectile for field purposes admits of being used indifferently either as solid shot or as shell, or common case or canister. It is composed of separate pieces, bound together so compactly that the shell has been fired through a solid mass of oak timber nine feet in thickness without sustaining a fracture. When used as a shell it divides into 49 separate regular pieces, and into about 100 indefinite and irregular pieces. It combines the principle of the shrapnel and percussion shell. . . . . It has been stated that the great defect of my shell was its small capacity for powder. If, instead of that, it had been stated that its great advantage was its large capacity, those persons who made the statement would have been nearer the truth. The shell of my thirty-two pounder admits twice the quantity that is contained in that of the ordinary gun, and there would be no difficulty in increasing the quantity. It has been urged that it would make so very small a hole in passing through the side of a ship. There may be some reason for that applied as a shot, but when applied as a shell it is the very thing I want. The shell is caused to explode in the act of passing through the timber, and the smaller the hole, the less will be the outlet for the explosion, and the greater the shattering effect. All the destructive effects will arise from the use of the shell."

We have received the following note from Mr. Scoffern, in which he politely compliments himself as "an author," and questions (by implication) our "authority":—"Dr. Scoffern presents his compliments to the Editor and incloses a note from Mr. Reed, which is self-explanatory. The justice of its publication in the MECHANICS' MAGAZINE will be obvious, and will spare the necessity of its publication elsewhere. The Editor will see the impossibility of plagiarism in this case, even assuming an author willing to rely on the authority of the MECHANICS' MAGAZINE. '199 Strand, May 5th, 1859. Dear Sir,—With respect to the priority of description of the Armstrong Gun, as between your book on New Resources of Warfare and the MECHANICS' MAGAZINE, I can testify that your delineation of Armstrong's Gun was drawn by me nearly a fortnight previous to its appearance in that journal. I am, very truly yours, J. C. REED. J. Scoffern, Esq., M.B.'"

Mr. Chas. Boner, dating "Ratisbon, Bavaria, April 30, 1859," writes as follows:—"In your journal, when speaking of Sir W. Armstrong's cannon, you observe, 'Nothing like the firing made with this gun at Shoeburyness has ever before been seen.' You will perhaps find it interesting to learn that this is not the first time an almost incredible range and *perfect* precision have been obtained with a weapon the charge of which was surprisingly small. In 1853 I was incessantly occupied with a plan for applying the rifling of small arms to cannon. After satisfactory experiments, I ordered a small cannon which was intended for trial in England. To lose no time, however, I went at once to London, taking with me pistols constructed on the same principle, and with which I had fired leaden as well as iron balls. The Select Committee at Woolwich, when they heard what the weapon was capable of performing, were incredulous; but on the 30th June, 1854, I fired at a target with a pistol, the barrel of which was 11 inches long, and the charge one drachm, at the iron target at 200, 300, and 400 yards, and should have continued at 500 yards, but Colonel Chalmers thought it better to leave off, as there were so many workmen about, and an accident, therefore, not improbable. The bullets struck the target almost immediately, and fell to the ground in the form of thin wafers, so battered were they by the force of the blow. Each shot fired at the several distances was marked down; and the different papers are still in my hands, signed by Col. Chalmers, and sealed with the official seal. With a carbine, loaded as easily as a musket, I am able to fire *with precision* at 800 yards. You may ask why were no further experiments made, or attention paid to the invention. This I am quite unable to tell you; and I only send you these facts, in the supposition that they may not be without interest for some of your readers. P.S.—You may perhaps care to know that with this method of rifling hardly any 'fouling' takes place; and that it makes little difference in the state of the barrel whether six, or eight, or sixty, or eighty rounds are fired."

Mr. Charles Maybury Archer writes:—"A constant and edified subscriber watching as I do weekly through the medium of your columns the progress of scientific project and achievement, permit me with your customary kindness to claim the paternity of one of my own offspring, even though it be by the unusual process of self-affiliation. One of your correspondents in last week's number, writing on the topic of telegraphs to China and Australia, subscribing himself 'Time is Money,' and dating from Vienna, March 31st, says:—'Before concluding, I beg to remark that the Atlantic Telegraph would now be in perfect working order if steps had been taken to obviate the total want of longitudinal expansion, or elasticity. This could easily be done by placing, at distances (which should be regulated by the length of the cable and geodetic formation of its resting-place), *conductive spring joints*, which would add a *little* to the bulk and first outlay, but would ensure the wanted elasticity and success of the enterprise.' This very proposal in minima particula, permit me to say I provisionally patented last year, and forwarded to the British Association Meeting at Leeds. It was shortly after reproduced by a gentleman at Manchester as his own, and it now comes from

Digitized by Google

Vienna! Trusting that, on the principle of tribute to whom tribute, &c., and being perfectly prepared to protect the paternity of the idea, I believe you will favour me with these few words of passing comment."

The last number of the *Photographic News* directs attention to some of the uses of photography for practical purposes. Very recently there happened, says the editor, to be a "slip," as it is technically termed, of some land, in connection with some public works. Of course the parties who had engaged the services of the civil engineers and contractors blamed them for insufficient work. As the case was one of importance and involved several thousands of pounds damage, the proprietors at once sent for an able photographer, and he, under the direction of another civil engineer, who was called upon to give his advice in the emergency, took a series of views from all parts, and in a manner to satisfy the most particular jury that ever was assembled. It will at once be seen that this was a most important step, because the proprietors were enabled to proceed at once with remedying the misfortune. Had they not availed themselves of photography they must have left the embankment in a dangerous state, hourly becoming worse, in order that a "jury of inspection" might be called upon to view and arbitrate on the matter. Besides this, another and striking advantage accrued: good and correct photographs prevented the possibility of "hard swearing." Because we may rest assured that in giving evidence the witnesses for the plaintiffs would be inclined to exaggerate the damage, while, on the other hand, the witnesses for the defendants would naturally depreciate its importance; but photography happily comes in between the two, and sets both sides right by giving truthful and correct information. May we not hope that the day will soon arrive when photography, wherever it can be used, will be made available for the purpose of promoting justice and equity between man and man. While on this subject, we may allude to another and most important application of photography. We allude to a suggestion made at the annual meeting of the Association for the Prevention of Boilers Bursting. This association originated in Manchester some time ago, owing to the great number of lives that were annually lost by the bursting of boilers in large manufactories. The association appoints several agents to inspect boilers, and to report on imperfect ones, so that they may at once be remedied. There can be no doubt but that this association has already saved several hundreds of lives, and it is to be hoped that similar associations will be formed in all the large towns, so as to prevent the great annual sacrifice of life which takes place simply for want of proper care and attention. One of the members of the Association has suggested that in future, when any of these unfortunate accidents occur, there should be photographs taken of the boilers that have burst in order that a museum of such photographs might be formed, with reports showing the cause of bursting. This suggestion, we are happy to learn, has been adopted, and in future photographic copies of all these accidents will be taken, as guides and warnings to others to keep clear of what had produced the fatal result.

The same well-conducted journal also directs attention to the important subject of priority of invention, in the following manner:—"Our object is to draw the attention of our readers to the importance of making known to the world, as soon as possible, their discoveries or improvements. We are daily receiving letters from persons who, having seen in our columns a description of some apparatus or improvement which they have previously found out, claim for themselves the priority of publication. When we see our continental brethren so jealous of their fame as actually to take, in order to secure a trifling discovery, the earliest possible date, our correspondents should be similarly watchful over the fruits of their own brains, and remember that the best way to secure the credit of any discovery is to publish the account of it before any one else; not to wait till another has benefited the world by a full publication, and then to come forward stating that the same idea had previously existed in their own minds."

Inventors are still bent upon the artificial adornment of the fair sex. A Mr. Speight, of Clerkenwell, "artist in hair," has just completed a patent for an invention which relates to fictitious plaits and curls for head-dresses. These have been commonly composed of human hair, but the inventor employs dyed hemp, flax, aloe, plaintain or rhea fibre, or dyed China grass. The fibre or grass having been first dyed of the required colour is next combed or heckled, and thus receives a gloss. Then, to manufacture it into curls, the patentee employs a fixed holder or hollow support, into which he inserts a rod slotted at one extremity. On this rod he places a tube slotted at one end, and having a pin through it at the other. The pin, taking in the slot in the rod, keeps the tube steady. The fibres in a damp state are attached to the slots in the tube, and the tube being caused to turn, the threads assume a curled form, and are attached to the ends of the pin. The tube is then removed from the rod, and a heater inserted therein to fix the curl in the desired form. Grease or similar material is next applied to the curl, which is finally subjected to a proper drying process, and is then ready for the use of such ladies as Mrs. Dombey's mother.

From a tree which is found growing on the Malayan peninsula and on the islands of the Malayan and Eastern Archipelago, the natives obtain a juice which, according to their simple manner of naming things, is, in many localities, called "suso-poko," signifying in English "tree milk." "Suso-poko is a substance," says Mr. Leonard Wray, "in which the good qualities of both india-rubber and gutta percha are happily blended, and which will render it most important to the commerce and manufactures of Great Britain." In the preparation of this rude natural product for home use, Mr. Wray first frees it from all impurities, either of woody matter or otherwise, by certain simple and well-known methods; then it may be at once used for a variety of purposes. In other cases, he hardens and materially changes the character of this cleansed product by means of chloride of sulphur. In order to dissolve it, and render it fit for manufacturing purposes, he treats it with naptha, bisulphuret of carbon, oil of sassafras, and other suitable solvents, and also with heat. Having prepared it, he applies it as a substitute for gutta percha, caoutchouc, and other similar substances; and, in some cases, mixes it with one or more of those substances.

Mr. John Fowler has just added to his many steam-ploughing inventions another which consists in so arranging the ropes by which the implement is hauled to and fro over the land, that every time the implement arrives at the headland it may be turned round either entirely or partially by the action of the traction rope. If it be desired to turn the implement entirely in this manner, the end of the traction rope is attached near one of the hinder corners of the implement, and is led round the back of the implement, and along one of its sides to a clutch in front, by which it is held while the implement is doing its work. When it is desired to turn at the end of the traverse, the traction rope is released from the clutch, and then, in unwinding itself from the implement, turns it half round so as to reverse its position ready for the next traverse over the land; at the same time it winds the return rope partially round the implement, and when this is made fast in the clutch it is ready to become the traction rope again.

A correspondent astutely signing himself "Toredo Navalis," writes:—"As you are about to notice Mr. Wray's paper on timber for ship-building in your next number, I beg to bring under your immediate notice my plan submitted to the Minister of Marine, at Paris, and to our Admiralty. The wood is introduced into a close vessel which is exhausted of air; any oil in which any *bitter* powder, cedar chips, or oil of creosote is infused, is then admitted, and forced in by the pump till the pressure is from 140 to 160 pounds to the square inch. Finally, the wood is coated to the depth of a fifth or sixth of an inch with the following composition, which no degree of heat or cold will ever affect:—Boil in a large iron pot any quantity of tar, and mix with it *charcoal* very finely powdered, stirring them all the time till the whole is reduced to a state of mortar; spread the whole on the wood with a *wooden* trowel."

Mr. J. W. Duffey, of Clerkenwell, writes us as follows:—"Believing you like to be informed of anything new, I beg leave to call your attention to the following, viz.: Uncovered wire for every variety of Electro-Magnectic apparatus, on the principle that two currents travelling in the same direction parellel with each other, will not interfere one with the other, or pass off in a lateral direction. Although this is opposed to the present theory, I can positively assert and prove it to be a fact. The description of a small induction coil I am manufacturing will give the best idea of its practicability and advantage. The core consists of a bundle of 16 iron wire, 2½ inches long, ⅜ diameter; primary wire, 2 yards of 16 copper wire covered. I use covered wire in this case because uncovered wire, while making the core strongly magnetic, induces a very feeble current in the small wire. (You will understand by this it does not interfere with the use of uncovered wire for the relay-magnet for telegraphing.) The small wire consists of two separate coils, 50 yards each; of 32 uncovered iron wire, six layers in each coil. Between each layer is interposed a layer of paper. Break-piece and connections same as those ordinarily in use. With the coils in connection so as to form a single coil of 100 yards, using a pint Smee's battery, gives a powerful shock."

We read in the *Greenock Advertiser*:—"A new feature has arisen in aquatics in this locality from the construction this season of a number of wooden screw steamers of small tonnage. Messrs. Cameron, boat-builders, East Blackhall-street, have recently launched two handsome little vessels of this description, about thirty feet in length, and belonging to Messrs. J. and W. Young, of Glasgow. Their engines, of 1½ h.p. nominal, are high pressure, and made of brass, and the screws are placed beneath the keel instead of at the stern post. It is expected that by this mode these tiny steamers will skim along at a rate of nine knots an hour. Messrs. Cameron have on the stocks another screw of thirty-eight feet in length, and remarkably fine model, for a gentleman in town. She will be fitted with a condensing engine of 4 h.p., and it is anticipated that she will steam very fast. Mr. Macdonald, boat-builder, Virginia-street, has nearly completed a fine clipper cutter yacht, of about fourteen tons, for the Earl of Morton."

Patents for Inventions.

PROVISIONAL PROTECTIONS.

Dated April 12, 1859.

911. D. Doiz, of Manchester, Engineer. Improvements in the construction of gas lamps. A communication from W. G. Ginty.

Dated April 18, 1859.

967. J. Luis, of Welbeck-st. An improved machine for raising water. A communication from M. Dupré.

969. W. Prosser, of Dorset-pl., Dorset-sq., Gentleman. Improvements in apparatus employed in the production of light.

971. J. Whitaker, of Leigh, Agricultural Machine Maker. Improvements in mowing machines.

973. M. A. F. Mennons, of Paris. An improved disinfecting compound. A communication from W. E. Lynch.

975. J. Izod, of Hoxton, Dealer in Fancy Goods. A safety cigar, vesuvian, or fusee box or case.

977. J. Freer, of Rothley, Leicester, Agricultural Implement Maker. Improvements in machines for planting grain and seed, and an improved seed feeder and meter for planting machines.

979. A. Dalrymple, of Sheffield, Tailor. Improvements in the mode of covering crinoline, and in machines used in connection therewith.

981. F. and W. Edwards, of Coventry, Machinists. Improvements in looms for weaving ribbons and other like goods.

983. J. Boydell, of Gloucester-crescent, Regent's-park. Improvements in the apparatus applied to the wheels of locomotive traction and other carriages to facilitate the draught.

Dated April 19, 1859.

985. P. and J. Reynolds, of Belfast, Engineers. Improvements in machinery or apparatus for hackling flax and other fibrous materials.

987. I. Dutton, of Tipton, Whitesmith, and R. Martin and T. Phillips, of Dudley, Coke Merchants. New or improved machinery for preventing accidents in coal or other mines, by the drawing of skips or cages over their pullies.

989. O. Maggs, of Bourton, Dorset. Improvements in cheese presses.

991. A. V. Newton, of Chancery-lane. Improved machinery for weaving seamless bags or other articles with hemispherical, or regular or irregular ends or forms. A communication from J. Pender.

Dated April 20, 1859.

993. J. Wotton, of Birmingham, Manufacturer. An improvement or improvements in raising or shaping metals.

995. A. W. Williamson, of University College. Improvements in obtaining extracts from the liquorice root.

Dated April 21, 1859.

999. A. F. Vanhulst, of Brussels. An improved kiln for drying malt.

1001. T. Dawson and J. Avery, of Essex-st. Improvements in pencil-cases, watch seals and keys, toothpicks, and other like articles of jewellery, lockets, penknife handles, porte-monnaies, and other like articles.

1003. J. Alison, of Hainault Forest, Essex, Gentleman. An improved instrument for extirpating thistles, docks, and other deep-rooted weeds.

1005. D. Auld, of Glasgow, Engineer. Improvements in machinery or apparatus for supplying steam-boilers with water.

1007. E. Lewthwaite, of Halifax, and G. Ambler, of Queenshead, near Halifax, Watch Makers. Improvements in clocks, watches, chronometers, and other time-keepers.

1009. G. Roberts and J. Bridges, of Vauxhall-bridge-road. Improvements in the manufacture of candles.

1011. J. H. Pepper, of Kilburn Priory. Improvements in apparatus for showing stereo-scopic pictures.

Dated April 23, 1859.

1013. R. Gray, of Sheffield, Crinoline Manufacturer. Improvements in crinoline skirts. A communication from J. Hobson.

1015. J. Edwards, of Aldermanbury. Improvements in the manufacture of buttons.

1017. J. Gillies, of Glasgow, Wood Turner. Improvements in branding or marking wood for casks, barrels, and other purposes.

1019. W. Dicks, of Leicester, Boot Maker, and W. Hopwell, of Leicester, Machinist. Improvements in machinery for making screws, and applying them in fixing the soles of boots and shoes.

1021. P. F. Mutel, Gas Burner Maker, and L. H. Blan-

chard, Gentleman, both of Paris. Improvements in gas burners.

1023. W. Gibson, of St. Leonard's-road, Engineer. Improvements in steering apparatus.

1025. J. Marshall, jun., of Selby, Gentleman. Improvements in filtering and depurating fluids.

1027. F. C. Maguire, of Stamford, Gentleman. Certain improvements in the utilization of sewage manure.

Dated April 25, 1859.

1029. W. P. Balfern and M. McKay, of Hammersmith, Soap Manufacturers. The manufacture of sweet-figged soft soap.

1031. G. Ward, of Blackburn, Thread Manufacturer. Improvements in machinery or apparatus for making healds.

1033. T. A. Weston, of King's Norton, Accountant. A new or improved pulley.

1035. J. Holmes, of Somerset, Accountant. Improvements in applying eyelet holes to boots and shoes, and in binding boots and shoes.

1037. E. Humphrys, of Deptford. Improvements in steering apparatus.

1039. H. C. Hurry, of Wolverhampton, Civil Engineer. Improved means of and apparatus for obtaining motive power.

1041. S. L. Taylor, of Cotton End, Bedford, Agricultural Engineer. Improvements in agricultural implements, in obtaining motive power for actuating such implements, and in apparatus connected with the application of steam power.

Dated April 26, 1859.

1043. H. Allman, of Hampstead-road, Consulting Engineer. Certain improvements in the construction of window-blind mountings, and in apparatus connected therewith.

1045. W. E. Newton, of Chancery-lane. Improvements in the manufacture of nitric acid and its application for the production of artificial nitrous or nitric salts. A communication from M. Lefebvre.

1047. W. Marshall, of Leith-walk, Mid-Lothian, Engineer. Improvements in steam-engines.

1049. R. A. Brooman, of 166 Fleet-st., London, Patent Agent. Improvements in steam-boilers. A communication from T. N. Meynier and L. A. Le Bleu, of Paris.

1051. J. H. Johnson, of Lincoln's-inn-fields. Improvements in machinery or apparatus for grinding and polishing knives and other articles of cutlery and tools. A communication from J. Dodge.

Dated April 27, 1859.

1053. G. Pearson, of Bugbrook, near Weedon, Contractor. Improvements in apparatus for cutting and shaping trenails.

1055. H. R. Fanshawe, of Old Kent-road, India Rubber Manufacturer. Improved apparatus or mechanism for drawing-off, filtering, and guaging liquids in butts, barrels, casks, and such-like vessels, preserving the contents from deterioration from contact with atmospheric air.

1057. J. R. Smith, of Glasgow, Gentleman. Improvements in obtaining motive power.

1059. C. Hamp, of Harrow-road. Certain improvements in locks.

1061. T. Lacey, of Grafton-st., Westminster, Gas Engineer. Improvements in gas regulators.

1063. T. Gauntley, sen., of Nottingham, Lace Manufacturer. Improvements in the manufacture of fringes.

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

1075. W. M. Cranston, of New Broad-st., Agent. A grass-cutting machine. A communication from W. A. Wood. Dated April 29, 1859.

1110. J. Morse, of Massachusetts. An improved power printing press. Dated May 3, 1859.

1111. L. R. Blake, of Massachusetts. A new and useful or improved machine for sewing a sole on a boot or shoe. Dated May 3, 1859.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(*From the London Gazette, May* 10, 1859.)

2962. F. W. Turner. Steam-engines, condensers, and boilers.

2989. R. A. Brooman. Washing and drying machinery. A communication.

2990. R. A. Brooman. Fire-arms. A communication.

2991. R. A. Brooman. Embroidering. A communication.

2992. R. A. Brooman. Splitting hides, &c. A communication.

3001. M. D. Wyatt. Wall coverings.

1. J. T. Pitman. Bungs. A communication.

3. A. Anderson. Governors.

4. B. J. Gosteau. Gridiron.

5. J. E. Drouot. Bakers' ovens.

12. P. E. Guérinot. Railway locomotives, &c.

17. J. Harris. Regulating the pressure of fluids.

19. G. Skinner and J. Whalley. Tiles.

22. A. L. Lévêque. Subduing horses.

23. J. B. Morgan. Propelling.

24. J. Luis. Candles. A communication.

30. J. Furnival, T. Furnival, J. Derbyshire, and F. J. Emery. Kilns and ovens.

33. J. B. Joyce. Wool-combing.

34. W. Hood. Racks and water cisterns.

35. A. Bedborough. Chimney cowl.

39. J. Howard. Plough.

40. R. Rumney. Printing and dyeing.

51. W. Spence. Photographing on wood. A communication.

60. H. Harden. Fire-bars for furnaces.

100. R. Mushet. Metallic alloy.

101. R. Mushet. Cast steel.

121. T. Sampson. Feeding steam boilers.

132. R. Mushet. Cast steel.

134. R. Mushet. Cast steel.

141. W. E. Newton. Sewing machines. A communication.

234. W. E. Newton. Life-preserving vests. A communication.

253. W. Crowther. Prussiates of potash, or soda.

310. H. C. Jennings. Paper, parchment, and gelatine.

332. N. Greenhalgh, W. Shaw, and J. Mallison, jun. Yarns.

443. H. Y. D. Scott. Cement.

594. W. Gossage. Treating ores of copper.

715. G. Gregg. Leather.

939. E. Partridge. Axles.

961. J. Sidebottom. Tubes.

988. A. W. Williamson. Liquorice root.

997. L. P. Porter. Knitting machinery. A communication.

1005. D. Auld. Supplying boilers with water.

1009. G. Roberts and J. Bridges. Candles.

1017. J. Gillies. Branding wood.

1023. W. Gibson. Steering apparatus.

1047. W. Marshall. Steam-engines.

1057. J. R. Smith. Motive power.

1075. W. M. Cranston. Grass-cutting machine. A communication.

1110. J. Morse. Power printing press.

1111. L. R. Blake. Sewing soles on shoes.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed May 6, 1859.

2482. A. Fryer.
2490. J. Platt.
2494. A. H. Dendy.
2496. T. MacSweney.
2497. W. Hale.
2502. E. E. Allen.
2504. J. F. Dickson.
2505. J. L. Jullion.
2507. A. Henderson.
2508. J. Felix.
2515. R. A. Brooman.
2516. R. M. Ordish.
2522. E. Humphrys.
2528. J. Blethyn.
2531. F. H. Maberly.
2535. J Rae.
2545. J. Wadsworth.
2555. A. B. Woodcock and J. M. Dunlop.
2566. W. Clark.
2567. W. Clark.
2599. C. Cowper.
2675. J. Luis.
2683. J. Luis.
291. M. Loam.
303. I. Clements.
391. J. Grimes.
527. J. Leigh.
569. H. Leonard.
628. N. Washburn.

Sealed May 10, 1859.

2258. J. Saxby.
2518. J. Corner.
2520. W. G. Taylor.
2524. A. J. Brooks.
2527. C. T. Judkins.
2534. T. Gray.
2542. G. T. Bousfield.
2546. W. Ashton and T. Cartmell.
2560. T. R. Butcher, F. Stevens, W. T. Johnson, and T. Jarvis.
2588. M. Scott.
2594. J. Platt and H. Chubb.
2604. J. Leslie.
2630. T. S. Cressey.
2666. A. V. Newton.
2692. W. Richards.
2700. H. L. Pattinson.
2784. W. E. Newton.
2792. J. Dawson.
2964. R. Hornsby, jun.
380. B. Burrows.
570. W. Tucker.
580. J. Leigh.

PATENTS ON WHICH THE THIRD YEAR'S STAMP DUTY HAS BEEN PAID.

1057. W. Bulmer and I. Sharp.
1068. R. A. Brooman.
1071. W. J. Curtis.
1076. L. G. Perreaux.
1088. A. V. Newton.
1095. F. Potts and T. Vann.
1099. W. Basford.
1101. G. Simpson.
1102. R. A. Brooman.
1113. B. Beniowski.
1287. A. Watson and A. H. Williams.

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned no to produce them without acknowledgement:—

STEAM ENGINES, &c., 2199, 2202, 2233.

BOILERS AND THEIR FURNACES, 2218, 2220.

ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 2196, 2221, 2227.

SHIPS AND BOATS, including their fittings, 2186, 2205.

CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 2193, 2241.

FOOD AND BEVERAGES, including apparatus for preparing food for men and animals. *None.*

FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 2190, 2194, 2204, 2206, 2214, 2216, 2224, 2228, 2230, 2238.

BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c., 2225.

LIGHTING, HEATING, AND VENTILATING, 2195, 2223, 2237.

FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 2198, 2226, 2231.

METALS, including apparatus for their manufacture, 2183, 2207.

CHEMISTRY AND PHOTOGRAPHY, 2203, 2240.

ELECTRICAL APPARATUS, 2187, 2188, 2189, 2192, 2208, 2239.

WARFARE, 2211, 2213, 2235, 2236.

LETTER PRESS PRINTING &c., 2197.

MISCELLANEOUS, 2184, 2185, 2191, 2200, 2201, 2209, 2210, 2212, 2215, 2217, 2219, 2222, 2225, 2229, 2232, 2234, 2240.

2183. J. J. RUSSELL. *Improvements in furnaces for heating iron and steel, suitable for the manufacture of welded tubes and other articles.* Dated Sept. 30, 1858.

Here each furnace is made with several fire-places at one end, which are separated from the body of the reverberatory furnace by a bridge. At the back end of the furnace is formed a hollow bridge, over and under which the flames pass from the fire-places and the body of the furnace to the chimney. This hollow bridge forms an oven from side to side of the furnace, for the introduction of the iron or steel, in order to the same being preparatorily heated. *Patent completed.*

2184. F. J. MONEY. *Improvements in the construction and adaptation of sewers.* Dated September 30, 1858.

The inventor constructs sewers with a pipe or connected pipes laid therein throughout their entire length, to afford separate channels, one for the liquid and the other for the sewage. He further arranges the sewage pipes that they may be connected with dwellings by branch sewage pipes independent of the ordinary water drains leading therefrom to the main sewer. *Patent completed.*

2185. W. BLAKE. *An improved portable fire-escape.* Dated October 1, 1858.

This fire-escape consists of a metal frame, in which a floor or panel is fixed, forming a platform which rests on the wooden sill of the window, and connected by rings at the back thereof is a tube, having an inner sliding tube, which, when extended, is kept so by a screw through the outer tube, or by studs at ends thereof, fixing into plates secured to window, thus forming a rod or bar across inside of window opening—a spring being enclosed and attached to the inner tube draws in same when released. *Patent completed.*

2186. J. T. P. NEWBON, T. SMITH, and J. BROWN. *An improved method of lifting and lowering ships' anchors.* Dated October 1, 1858.

The patentees employ a bevel or spur wheel for each anchor fixed vertically in openings made in the deck, and worked with one or more pinions with a connecting-rod or shaft if required. By arranging this handle or lever-rod as a socket-bar or a moveable capstan head for working each apparatus, it can be removed from out of its place on deck, and when not required the deck is disencumbered, and the socket holes into which the socket-bars or capstan heads are shipped may be fitted with flap covers or plugs. A friction-lever and brake is added. *Patent completed.*

2187. M. HIPP. *Improvements in electric telegraphs.* Dated October 1, 1858.

This consists in a novel application of the induction current, and differs from the systems hitherto used, in that the telegraphic signals are produced exclusively by the induction current at the moment of the primary circuit being broken, and that the induction current produced at the moment of the completion of the primary circuit only serves to increase or strengthen the effect of the former. *Patent completed.*

2188. J. W. WILKINS, and J. B. DUNN. *Improvements in constructing electric telegraph cables.* Dated Oct. 1, 1858.

The interior of this cable is made by the use of a helix produced by a narrow band or strip of copper. This helix is formed by bending the strip of metal on a cylindrical mandril. On this helix a coating of gutta-percha, &c., is applied, so as to produce a cylinder on which is placed a series of narrow strips of copper, the edges of which are kept separate and at a distance apart. These bands are bent spirally around the cylinder of insulating material, forming very long spirals, the strips of metal only slightly inclining to the central axis of the cable. Over these, gutta-percha, &c., is applied. To complete the cable a band or bands of hemp is bound around the last coating of insulating material. *Patent abandoned.*

2189. SIR E. BELCHER. *Improvements in the manufacture of telegraphic cables.* Dated October 1, 1858.

The interior conducting wires of the cable are first covered with beads of glass, porcelain, bitumen, resin, &c. The wires so covered are then passed through a fluid cement of resin, and are then immediately covered with a tube of gutta-percha, so as to retain the non-conducting cement in a fluid state within the tube of gutta-percha. The tube of gutta-percha may then be surrounded with animal or fish glue, and then by a coating of wire. *Patent abandoned.*

2190. T. PRESTON. *Improvements in the manufacture of looped fabrics.* Dated October 1, 1858.

According to this invention the lower guide bar has as

Digitized by Google

many guides as there are needles, and it is caused constantly to lap over one needle first in one direction and then in the other. Another improvement consists in arranging the lower guide bar to be shogged or moved to the extent of two needles, and the guides are caused to lap first on one of such two needles at one course and then on the other needle for the next course. Another improvement consists in combining the use of printed or parti-coloured yarns or threads in knitting machines with the use of points to take off and change the loops from some of the needles to other of the needles of the machine. *Patent completed.*

2191. H. BRADBURY. *Improvements in producing printing surfaces from engraved plates.* Dated October 1, 1858.

This invention was described at page 257, No. 16 of the MECHANICS' MAGAZINE (New Series). *Patent abandoned.*

2192. J. ROGERS. *Improvements in submarine electric telegraph cables.* Dated Oct. 2, 1858.

Here the wire or strand of wires has laid round it, longitudinally, a number of plated bands of fibre, so as entirely to surround it, and the bands are secured to it by binding them round with twine. The whole is then covered by plaiting over it yarns or cords of fibrous material. *Patent completed.*

2193. L. D. OWEN. *Improvements in ploughs for digging up potatoes, and for other purposes.* (A communication.) Dated Oct. 2, 1858.

This consists in having the support or standard of the beam of the plough shaped so as to form a coulter, with a pointed foot, and on or to the point or front part of such foot the share is fixed by screws, and on or to the back part of the foot which usually forms the mould-plate or board-prongs arms are fixed or placed in a kind of conical form at a convenient distance apart, the centre prong or arm, or that which is the top from the ground, is supported by or on a projection on the standard made thereon, and is fastened to the standard, or to the mould or frame-plate, as may be desired. There are several modifications included. *Patent abandoned.*

2194. W. BRIERLEY. *Improvements in looms for weaving carpets and other fabrics.* Dated Oct. 2, 1858.

This relates chiefly to the weaving of Scotch carpets by power, and consists in so arranging and applying mechanism or apparatus in connection with a jacquard-machine as to render such looms self-acting in the production of the various figures or designs required in such fabrics. *Patent completed.*

2195. H. MONIER. *A new gas burner.* Dated Oct. 2, 1858.

This consists, 1, in using vitrifiable transparent materials for manufacturing gas and other burners. 2, in certain new forms and arrangements of the said burners, shown in the drawings, without reference to which the invention is not described. *Patent completed.*

2196. B. SAMUELSON. *Improvements in the wheels of carts and other carriages to be used on common roads.* Dated Oct. 2, 1858.

The patentee claims, 1, the construction of wheels to be used on common roads with bent wrought iron or steel spokes of hollow section, so placed that when the wheel is complete the flat convex external part of the spoke shall be next to the tyre, and the opposite hollow or concave part shall be toward the nave, the hollow form giving stiffness, and its position facility for riveting, and space for rivets of good size. 2, varying the angles of the spokes to the centre of axle by regulating pieces attached to the moulding-box, in which the nave is run upon the spokes. 3, the application of steel or steeled tyres to common road carriage wheels of this improved or any other construction. 4, the use of tyres which are hollow towards the nave, in connection with wrought iron or steel spokes; the stiffness of the wheel being, in this case, derived chiefly from the tyre itself, so that the form of the spokes is less material than when a tyre of the ordinary form is used. *Patent completed.*

2197. H. G. COLLINS. *Improvements in the production of blocks or surfaces to be used in printing.* Dated Oct. 2, 1858.

Here the drawing, device, &c., is obtained on a block or surface to be used in printing, from a drawing, device, or matter on a lithographic stone or other surface, whether the same has been produced thereon by hand, transferred, or otherwise, by subjecting the drawing, device, or matter on the lithographic stone or other surface to a series of processes similar to that in which a lithographic stone is inked when about to be printed from in the ordinary manner; but the ink or composition used is to be mixed with suitable driers, so that each succeeding coating of the composition may quickly dry or set before the next coating is applied. By these means the lines and parts constituting the drawing, device, &c., on the stone, which would be inked and printed from if used in the ordinary manner, becomes more and more built up or raised, and when such raising has been sufficiently accomplished a cast in wax or other suitable material is taken, from which an electrotype is obtained, as is well understood. *Patent completed.*

2198. J. C. and E. W. HOLMAN. *An improved pianoforte action.* Dated October 2, 1858.

According to this invention, which has reference chiefly to upright pianofortes, the "dampers" are placed so as to act immediately beneath the hammer heads, and are connected with the keys in such manner so as to afford greatly increased facility for adjustment, and to maintain the same weight of touch whether the loud pedal be in action or not. *Patent completed.*

2199. A. V. NEWTON. *An improved governor for marine and other steam engines.* (A communication.) Dated October 2, 1858.

This consists of a small steam-engine working independently of the engine whose speed is to be governed, and applied so as to drive certain mechanism which offers an unvarying resistance to its motion, and is combined with mechanism driven by the engine to be governed, the whole of the mechanism being so combined as to work a regulating valve, which controls the supply of steam to the last-named engine. *Patent abandoned.*

2200. S. STIMPSON. *An improved construction of faggot or fire-lighter.* Dated October 2, 1858.

To give the fabric increased stability, the inventor arranges the pieces of wood of which it is to be formed so that they will lock together somewhat like the stones of an arch, and thus integrant portions will have less tendency than heretofore to slip out of place when subject to rough handling. *Patent completed.*

2201. R. DOLBY and J. GATES. *An improved process of transfer printing, and ornamenting on glass and other transparent substances.* Dated October 4, 1858.

The inventors take a composition of boiled linseed oil and lamp black, and transfer it to the glass or other transparent substance, after which they coat it over with an enamel, cement, or other hardening material. *Patent abandoned.*

2202. L. A. NORMANDY, jun. *An improved apparatus for the prevention of boilers exploding from a deficiency of water.* (A communication.) Dated October 4, 1858.

This invention is not described apart from the drawings. *Patent abandoned.*

2203. L. A. NORMANDY, jun. *Improvements in the manufacture of sulphate of copper.* (A communication.) Dated October 4, 1858.

That which constitutes this invention is the solution of metallic copper, and the production of sulphate of copper by heat, and with apparatus consisting of a succession of tubes used in a peculiar manner. *Patent completed.*

2204. M. VAN PETEGHEM. *Improvements in looms for weaving figured fabrics.* (A communication.) Dated October 4, 1858.

This relates to an arrangement of the parts of looms for weaving figured fabrics, whereby reading off the pattern to be woven may be effected automatically in the loom itself during the process of weaving. The pattern to be woven is painted or printed upon a sheet of wire gauze or perforated metal with some substance of sufficient consistency to resist the push of a set of needles with which the meshes are successively brought into contact as it is caused to travel onwards. These needles are made to act upon a set of rocking levers, whose other extremities are connected with the warps. It will therefore be understood that, as the needles are presented to the wire gauze, those needles which do not come into contact with the pattern will pass through the meshes and remain inoperative, whilst those needles which do come into contact with the pattern will be thereby prevented from passing through the meshes, and will, by acting on their respective rocking levers, act upon and raise those warps required to form the pattern. *Patent abandoned.*

2205. F. TREVITHICK. *Improvements in applying sails and keels to boats and vessels.* Dated October 4, 1858.

The patentee constructs the sails of ships of strips of thin sheet metal, which he combines by chains or wire ropes stretched between yards or booms, and for fore and aft sails the strips of metal may be arranged in an upright position, and connected by chains or wire ropes, so as to wind round a revolving mast. In applying keels to boats fixed tubes are used at intervals, parallel with the centre or keel of flat-bottomed boats or vessels. Through these tubes chains or cords are passed, to which the keels are attached, and other cords or chains pass over the sides of the vessels which are also attached to the keels, and by which the keels may be lifted into the vessel, or be brought to act as lee-boards. *Patent completed.*

2206. J. MILLS. *Certain improvements in machinery or apparatus for roving, slubbing, or spinning cotton and other fibrous materials.* Dated Oct. 5, 1858.

This applies to "roving frames" and "slubbing frames," which machines (when used for flax) are sometimes called spinning frames, and consists in a novel arrangement and construction of the "bush" or support in which the spindles revolve, the improvement being effected by steadying the spindle from the outside of the bush, by attaching the "bobbing-braid" to an inner revolving bush, either by screws at the top or otherwise, leaving sufficient space between the outer and inner bush to prevent any friction of contact. *Patent completed.*

2207. A. BESSEMER. *Improvements in the manufacture of iron and steel, and in apparatuses to be employed therein.* Dated Oct. 5, 1858.

This invention is described and illustrated on another page of this Number. *Patent completed*

2208. C. E. OLDERSHAW. *An improved method of constructing electric telegraph cables.* Dated Oct. 5, 1858.

This consists in constructing telegraph cables so that they may be sufficiently buoyant as to remain at from about 100 ft. to 200 ft. below the surface of the ocean. The conducting wire or wires is or are first insulated with gutta-percha, &c.; round this is applied a layer or coating of cork, and the whole covered with two layers of cord in a spiral direction, the one layer being in reverse of the other. These fibres may be protected by tar, caoutchouc, or other protecting agent. To prevent the shore ends of the cable from resting upon the bottom of the sea, and being injured by friction upon the ground, a covered duct, tube, or channel is used at both ends, and carried sufficiently far from the shore to enable the cable to be suspended free from rocks, &c. *Patent abandoned.*

2209. W. MENELAUS. *Improvements in machinery for straightening rails and wrought-iron bars.* Dated Oct. 5, 1858.

This consists of a block or standard, carrying a bell crank lever, in which two or three rams, or sets of rams, are fitted, one ram or set of rams to act horizontally, and the other ram or set of rams to act vertically; and of an angular bar, in which the rail or bar to be straightened is supported. The bar rests upon, and is received against, two sets of bearings, each set being composed of two or more blocks, three being preferred. The rams are so placed, with respect to the blocks, as to work between them. At every stroke of the lever the two sets of rams are brought into action, and as fast as each portion of the bar is straightened it is pushed forward by the action of the machine, or otherwise, until its whole surface has been acted upon. The invention also consists in adjusting the stroke of the rams by means of screws, or other equivalent agents. *Patent completed.*

2210. M. HENRY. *Improvements in the means of or arrangements for working steam expansively.* (A communication.) Dated Oct. 5, 1858.

This consists in certain means for working steam expansively. Separate slide valves are employed for effecting the induction and eduction of the steam, which separate valves have such gear or appliances, and are so arranged and acted on, that they may be regulated independently of each other, and the induction may thus be controlled without interfering with the regulation of the eduction, and *vice versâ*. *Patent completed.*

2211. J. H. BROWN. *Improvements in the manufacture of projectiles.* Dated Oct. 5, 1858.

Here, in the manufacture of projectiles, the forward ends of which are conical or tapering, a conical or tapering internal passage is formed in each projectile, in which passage is made one, two, or more spiral internal projecting threads. These balls or projectiles have no surrounding grooves to receive the lubricating matters, but in place thereof two thin discs, by preference of metal, are used to each projectile, one against the base or hinder end of a projectile, and the other a short distance away therefrom. Between these discs the lubricating matters are placed, and over these, and also over the end of the projectile, a cap of properly-prepared paper or of properly-prepared animal skin is used. *Patent completed.*

2212. G. HAMILTON and W. H. NASH. *Improvements in locks.* Dated Oct. 5, 1858.

According to one part of this invention a lock is constructed of two or more discs, which turn around a common centre, and a portion of the circumference of each of the discs projects beyond the frame or case of the lock and serves as a bolt. A portion of the circumference of each of the discs is cut away, so that the discs may be all turned round into such a position that no portion of them projects behind the frame, and when they are in such a position the lock would be unlocked. The discs are placed at a distance apart from each other, so that the portion of each of the discs which projects beyond the frame when the lock is locked may fit into slots cut in the striking-plate or piece into which a bolt is ordinarily shot. Between the discs there are friction-plates, which keep the discs in any position in which they may be placed. A portion of each of the discs is cut away at the centre, and projections on a key enter the spaces so formed, which projections act on the discs and move them round into such a position that no portion of their circumference projects beyond the frame when the key is turned into a certain position. *Patent completed.*

2213. J. H. BROWN. *Improvements in the manufacture of cartridges.* Dated Oct. 5, 1858.

In this invention cases are made of a slightly-conical form, of paper, or of other material, so as to be shaped into thin tubes. The diameter of the lower part of the tubes is made to agree with the bore of the gun. The tubular cases are of such strength as to admit of the contents being forced through by a ramrod into the gun, when the lower end of the cartridge is introduced into the muzzle of a gun or fire-arm. The balls are placed in the upper ends of the lining or inner cases upon the powder, where they fit tightly, but readily admit of being forced inwards by the ramrod. When the ramrod presses a ball into its case, it opens the closed end of the lining or inner case, and the powder and ball are forced into the barrel free from the case and lining. *Patent completed.*

2214. J. MILNES. *Improvements in weaving fabrics where cross-weaving is employed.* Dated October 5, 1858.

This relates to a former patent granted to E. Heywood. The present improvements consist in combining the use of Jacquard, or perforated cards, or chain of pins or pegs with such description of looms, in order that such looms may be caused to work for any desired length of time to produce cross-weaving, and then, by reason of the perforated cards, or chain or pegs, to change the character of weavings produced, and to combine the working of the loom for such change of weavings of any desired length of time; then again to change back to the weaving of cross weaving, and so on, according to design, the perforated cards or pattern surfaces being suitably arranged to produce the extent of cross-weavings and other weaving which shall be produced in succession. The "take up" of the looms is arranged so that when the looms are working to produce cross-weavings, the speed of the "take up" shall be greater than when making to produce other weavings, so that more picks of weft may be thrown in when not making cross-weavings. And such changes in the "take up" come into action by the working of the looms at the times when the classes of weavings are changed. *Patent abandoned.*

2215. G. LOVETT. *Improvements in portable apparatus for administering hot air, vapour, and shower-baths.* Dated October 5, 1858.

The vapour and shower-baths being usually administered in close succession, the inventor constructs the apparatus so that the patient may receive them both at one sitting. *Patent abandoned.*

2216. M. JACOBY and F. R. ENSOR. *Improvements in the manufacture of bobbin-net, or twist lace, and other fabrics made in twist lace machines.* Dated Oct. 5, 1858.

This is applicable, 1, in the manufacture of breadths of twist lace, and other fabrics, with scolloped edges; 2, when making breadths of twist lace with pure edges. To make scolloped edges to breadths of fabrics made in twist-lace machines, the carriage threads, which go to make the scollops, are arranged to work so that they may, as the width of work decreases when making scollops, be progressively moved towards the opposite selvages of the breadth, and work in the other parts of the work, or be otherwise employed; and again, as the width of the work increases in making a scollop, the carriage threads, which go to make the scollops, are progressively brought into the scollops, and so that when making the widest work the carriages are ranged to act with their warp threads, as a single tier of carriages regularly spaced with their warp threads. *Patent completed.*

2217. J. LUIS. *A new method of joining sheet-iron, cast-iron, gutta-percha, and other tubes, by means of muffles.* (A communication.) Dated October 6, 1858.

This invention is not described apart from the drawings. *Patent completed.*

Digitized by Google

2218. G. HEPPELL. *Improvements in the construction of boilers, furnaces, and flues.* Dated October 6, 1858.

The inventor proposes to have one boiler, which he calls the steam-generating boiler, and another completely enveloping or encasing the former, which he calls the heating boiler. His arrangement is, therefore, to have the inner or steam-generating boiler heated by contact with the water and steam in the outer boiler, which in its turn is heated by peculiarly-arranged furnaces. *Patent abandoned.*

2219. G. COLLIER. *Improvements in winding machines.* Dated October 6, 1858.

The object here is to obtain a uniform speed to the yarn or thread in laying it on to the bobbins, pins, or such like forms. The patentee gives a varying speed to the driving cylinder or cylinders, to drive such cylinder or cylinders faster when the yarn or thread is being wound on to the smaller part of the required form, and slower when being wound on to the larger part. *Patent completed.*

2220. M. HARNETT. *Improvements in preventing incrustation in steam-boilers.* (A communication.) Dated Oct. 6, 1858.

This consists in introducing oil, or oleaginous matter of any kind in a liquid state into the interior of steam boilers or generators, whereby the incrustation, so injurious to boilers, is effectually prevented. *Patent abandoned.*

2221. C. HILL. *Improvements in omnibuses and in apparatus for upholding the windows of omnibuses, and other carriages.* Dated October 6, 1858.

The patentee applies a raised footpath from end to end of an omnibus, the space below such footpath being open or clear for the feet of the passengers occupying seats. That the window of an omnibus, &c., may be upheld in any desired position, a strap is fixed thereto at its lower end as heretofore. This strap passes over a roller, and under an eccentric which turns on suitable necks or axes. This eccentric is grooved or roughed where it comes in contact with the upper surface of the strap, so that the weight of the window when partly raised will by drawing on the eccentric surface cause it to press the strap strongly between its surface and the surface of the roller below, and thus securely uphold the window. *Patent completed.*

2222. J. RIDSDALE. *An improved reservoir or fountain pen.* Dated October 6, 1858.

This consists mainly in adapting a flexible tube to a metal or similar tube or penholder, so that the end of the flexible tube nearest the pen shall be drawn to a small or capillary bore, and the other end of the said tube be hermetically sealed. On squeezing the tube, so as to compress it throughout, or nearly throughout its length, the contained air will be pressed out, in which state if the pen be dipped into ink until the open end of the tube touches its surface and pressure is removed, a certain quantity of ink will be raised into the tube by atmospheric pressure as the elastic tube expands to its accustomed size and bore. Another metal or other like tube may be slipped over the exposed top portion of the flexible tube, and slid on to the penholder, so as to lengthen it and render it more convenient for use; and a portion of the metal tube may be cut away sufficient to allow the fore-finger to press on the flexible tube to force a flow of ink when desired. *Patent completed.*

2223. W. MALAM. *Improvements in apparatuses for the manufacture of gas.* Dated October 6, 1858.

This consists in a new arrangement of apparatuses for the manufacture of gas from oils and grease, alone, or combined with gas from coal or other like carbonaceous materials. Over a fire, protected by fire-lumps, the patentee places two retorts into which oil is fed through gauze tubes from above. Over these retorts in a chamber he places coke, and above this chamber he fits a vessel containing fat or grease. Flues from the furnace at the bottom of the apparatus surround the coke chamber and grease vessel. The gas generated from the fat or grease is made to descend and mix with that from the oil, and is passed through one or more strata of cleansing material. Instead of coke ordinary coal may be placed in the coke chamber, when it becomes an ordinary retort, and the gas generated from the coal may be mixed or not with that from the oil and grease. *Patent completed.*

2224. D. SCATTERGOOD and R. W. SMITH. *Improvements in machinery for the manufacture of looped fabrics.* Dated October 6, 1858.

The object here is the construction of straight hosiery frames for making plain and ribbed selvage work, whereby more speed in working is obtained than heretofore, and the frame is less costly, and less liable to get out of order than the ordinary hosiery frames. *Patent completed.*

2225. C. BAYLIS. *An improved mode of constructing and arranging underground chambers in populous cities or towns for the reception of gas and water-pipes, and telegraph wires.* Dated October 6, 1858.

These underground chambers are composed of lengths of cast iron or other tubing of any suitable or convenient size and form, and joined together at their ends so as to form a continuous chamber or gallery in which openings are made at top, either in all the lengths of tubing or at such convenient intervals as may be desired. *Patent completed.*

2226. D. NICOLL. *Improvements in the manufacture of cloaks and other garments, and for their application to purposes to which they have not hitherto been applied.* Dated October 7, 1858.

This consists, 1, in manufacturing cloth by power or by hand looms for cloaks and other garments in separate circular forms or webs with a finished edge, selvage, or border. 2, In cutting these and other garments by steel stamps or knives actuated by the pressure of a heavy weight or spring. 3, In the application of these garments to purposes of covering in lieu of tents in the field. 4, In the application to cloaks and other garments of strong stays composed of flax or some strong fibre, such stays to be either introduced in the process of weaving the circular forms or webs of cloth, or subsequently by being attached to the same and in parts where additional strength is required to resist pressure. *Patent completed.*

2227. C. H. THURNHAM. *Improvements in the construction and application of certain mechanical arrangements to be adapted to the wheels of locomotives, carriages, and other vehicles for facilitating their traction and draught.* Dated October 7, 1858.

This consists in a peculiarly-constructed ring which can be slipped over the tyre of the ordinary wheels of vehicles of every description, and is retained in its situation by being channelled so that the carriage wheel can work therein, and while itself rotating, will rotate the external ring, which thus becomes a kind of annular railway or tramway for the several wheels of vehicles thus provided to travel upon. *Patent abandoned.*

2228. E. J. SEYD and J. W. N. BREWER. *An improvement in the preparation of paper to render writing thereon indelible.* Dated Oct. 7, 1858.

This refers to a preparation of paper by applying to it an aqueous solution of ferrocyanide of potassium, which paper so prepared, when dry, and written on with common writing ink, renders such writing indelible. *Patent abandoned.*

2229. J. C. NOUVIAT. *Improvements in stopping or stoppering bottles and other vessels containing non-gaseous liquids.* Dated Oct. 7, 1858.

The patentee employs a stoppering cap which is fitted to the bottle or vessel, and is provided with such arrangements as to keep the contents of such bottle or vessel hermetically closed, but which arrangements are so contrived that, when it is desired to pour out the contents, atmospheric air may be caused, without having to detach the cap, to communicate with and exert pressure on the liquid, so as to balance the pressure of the atmosphere on the spout or exit, and permit the outflow. *Patent completed.*

2230. D. NAYLOR. *Improvements in looms for weaving carpets and other fabrics, and in the methods of manufacturing the same.* Dated October 7, 1858.

This consists, 1, in employing in connection with the Jacquard apparatus a series of shuttle-boxes at each end of the slay or lathe, which are governed in their motion by suitable hooks acted upon by the cards; 2, in a double weft motion, the forks of which are near each end of the reed, and placed at right angles with the slay or lathe; 3, in forming the picking shafts of two or more parts, which can be disconnected as required by hooks and pattern cards, thus making the pickers perfectly independent of each other, and providing the means of allowing one to be stationary while the other is working, or putting them both out of gear when the pattern is adjusted; 4, in employing edging levers with projections above and below for guiding the wefts and regulating the selvages of the cloth, the said levers being governed in their action by hooks and pattern cards; 5, in attaching to the stop-rod certain inclined or cam-formed levers which act against studs or rollers in order to prevent any pressure on the swells at the time of picking; 6, in causing the catch of the ratchet-wheel to be lifted off by a hook and cards, or connecting it with the stopping apparatus, so that the pattern of the cloth or carpet may be varied, or the ratchet-wheel stopped when separate motion is required, either for the loom or Jacquard apparatus; 7, in employing wires, cords, or strips for preventing the numerous threads of weft from entanglement, in making grooves in the Jacquard cylinder, and placing in them bands of gut, &c., connected to elastic bands or springs to obtain the certainty of throwing off the card when it has done its work; and also in furnishing each shuttle with one or more extra drag pins, and delivering the yarn at the bottom instead of through an eyelet in the side; 8, in forming an improved texture of cloth or carpet by picking one pick of ground and one pick of colour, both of which are governed by two cards, another card being employed for raising the shed of the warp in two equal heads, so as to be able to throw a pick of wadding, yarn, or other material between the two cloths, and thus bind them together. *Patent completed.*

2231. N. FELLOWS. *Improvements in tea-kettles and other like domestic vessels.* Dated October 7, 1858.

This consists in forming the bottom of tea-kettles, &c., concave, and carrying a pipe from the bottom through the body of the vessel and out at the side or top thereof, so as to form a flue or flues through which flame and heat may pass, thereby presenting a large heating surface and preventing the kettle, &c., choaking the fire. *Patent abandoned.*

2232. F. RANSOME. *Improvements in preserving wood.* Dated October 7, 1858.

Here the wood is either coated or impregnated with a solution of silicate of soda or potash, and then with a solution of chloride of calcium, or with a solution of chloride or other soluble acid salt of iron, copper, zinc, lead, or barium. *Patent abandoned.*

2233. E. R. HANDCOCK. *Certain improvements in machinery applicable to engines to be worked by steam and other motive power.* Dated October 7, 1858.

This invention is said to consist in changing a rectilinear into a circular motion without dispensing with the crank action or its use. *Patent abandoned.*

2234. J. LUIS. *A new cutting and stamping press.* (A communication.) Dated October 8, 1858.

The principles upon which this invention rests are, 1, on the screw and nut being placed inside the piston or running box; 2, on the piston being guided internally and externally by the eye of the frame or cage and by the nut; 3, on the nut depending on the eye or fixed in the eye; 4, on the suppression of all the tie-pieces, braces, &c., fixed on the frame for guiding the piston. The presses, punches, &c., vary in size and form according to the use to which they are to be applied. The eye, whatever be the size, strength, or use the press is intended for, is composed of but one frame, either of cast iron or other metal; and adapted to this are, first, the nut either formed with the eye or adapted to it; second, the piston; third, the screw; fourth, the cap round stop-bar or springs for raising the piston. The invention is not described apart from the drawings. *Patent completed.*

2235. J. LEITCH. *An improved method of constructing fire-arms.* Dated October 8, 1858.

The inventor constructs the barrel and breech of the gun much in the ordinary way, except that the back end of the breech is bored entirely through, the back being closed by a cylindrical metal plug larger in diameter than the bore, placed with its axis at right angles with the barrel of the gun. The upper side of the plug has a channel grooved through it to allow the charge to be inserted through the back end of the breech, when, by turning the plug a quarter round, the cylindrical surface of the plug is presented to and closes the back end of the breech. Its action somewhat resembles that of a common water-tap. The connection of the barrel with the breech not being disturbed, a gun so constructed may be used indiscriminately either as a muzzle or a breech-loading fire-arm. *Patent abandoned.*

2236. E. V. RIPPINGILLE. *The improvements of fire-arms and artillery.* Dated October 8, 1858.

This invention is not fully described apart from the drawings. *Patent completed.*

2237. T. WALLER. *Improvements in stoves and fire-places for the prevention of smoke and the better ventilation of apartments.* Dated October 8, 1858.

This consists in admitting streams of atmospheric air through slots or apertures formed in the sides or backs of stoves or fire-grates just above the incandescent fuel, and of constructing the sides of the grates or stoves so that the rising smoke shall be caused to impinge thereon, and be intermixed with atmospheric air, whereby most of the products of combustion will be converted into flame, and the production of opaque smoke be prevented. *Patent abandoned.*

2238. J. and H. MITCHELL, and T. ENGLAND. *Improvements in means, machinery, or apparatus employed in spinning wool, mohair, alpaca, silk, and other fibrous substances.* Dated October 8, 1858.

This relates, 1, to spinning mottled yarns, made by combining two rovings of different colours, which are drawn simultaneously, and spun together, and that the proportions of such colours may be varied and still have the rovings from which they are made or spun of equal thickness, the patentees employ an additional pair of "back rollers," each pair being driven independently of the other pair, which, by change gear, they can vary in relative speeds. 2. The invention relates to combining long and short wools in the same yarn, and consists in having the framing or stands which carry the aforesaid two pairs of back rollers so arranged that each pair can be set or adjusted to the particular length of staple or length of fibre of each sort or substance. *Patent completed.*

2239. R. SEARLE. *Improvements in insulating and preserving and laying submarine and other telegraphic wires or cables.* Dated October 8, 1858.

This consists, 1, in the application of caoutchouc, wood, cork, or cork wood, for insulating the insulator of submarine telegraphic cables. 2, In the application of the before mentioned substances, or any of them, for reducing the specific gravity of submarine telegraphic cables. 3, In the application of the before mentioned substances, or any of them, as buoys for sinking or sustaining submarine telegraphic cables. 4, In the application of tubes composed of metallic wire, whether spiral or otherwise, in covering and protecting submarine or other telegraphic cables. *Patent abandoned.*

2240. A. NICHOLLS and T. WALKER. *An improved spring-hook, catch or fastening.* Dated October 8, 1858.

This consists in so shaping and arranging one piece of metal (say steel) to act as a spring when doubled or bent about the middle, and having the one end so formed as to lap slightly over the other, and thereby making a spring hook, catch, or fastening, which is applicable as a spring hook and eye when employed in securing wearing apparel. *Patent completed.*

2241. W. A. MUNN. *Improvements in horse-hoes.* Dated October 8, 1858.

This consists of an apparatus for thinning young growing crops by rotary knives, cleansing them from insects, and destroying such insects by rotary brushes and rollers combined with an ordinary horse-hoe, and which admits of the said several processes of thinning, cleansing, and ordinary hoeing being carried on simultaneously or separately. The invention is particularly applicable to the cultivation of turnips. *Patent completed.*

2242. T. ROBERTS and J. DALE. *An improved process for obtaining salts of soda and other alkalies.* Dated Oct. 8, 1858.

This consists in a method of producing nitrate, arseniate, and stannate of soda or potash or other alkalies. And the process for producing nitrates of the alkalies consists in passing the nitrogenous gases evolved in the manufacture of arsenic acid from nitric acid and arsenious acid, and this the patentees effect by pouring upon arsenious acid a quantity of nitric acid, sufficient to convert the arsenious acid into arsenic acid. The evolved nitrogenous gases are made to pass into the alkalies or their carbonates, but they prefer to use the alkalies in the caustic state. The vessel containing the alkalies is provided with agitators, so as more effectually to mingle the nitrogenous gases with the alkaline solution; or they pass the nitrogenous gases into a tower, through which is made to flow the alkalies in question, whereby they produce nitrates of the alkalies employed. It also consists in a method of producing arseniates of soda, potash, or other alkalies, and this they effect in the manner following:—They take chloride of sodium, chloride of potassium, or chloride of ammonium in a suitable vessel and add to any such chloride so much arsenic acid in solution as shall be sufficient to decompose these chlorides, whereby they obtain arseniates of the alkalies employed and solutions of muriatic acid, or they take nitrates of the alkalies, whereby they obtain arseniates of the alkalies and liberated nitric acid. It also consists in obtaining the salt known as stannate of soda, by taking metallic tin, to which they add a solution of caustic potash or soda. These are brought up to the boiling point in an iron vessel. They now add so much nitrate of soda as shall be sufficient to effect the solution of the tin. The metallic tin is rapidly oxidised by the decomposition of the nitrate employed, whereby is produced stannic acid, and ammonia. The ammonia is collected or conducted into arsenic acid, and the stannic acid combining with the soda or other alkali, produces stannite of such alkalies. There are various modifications included. *Patent completed.*

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, MAY 20, 1859.

THE IRON STEAM FRIGATES OR RAMS.

It is now decided that the Thames Iron Company is to build the first of the huge iron-coated steam frigates or rams for the Royal Navy. The design selected by the Lords of the Admiralty was prepared by the Surveyor of the Navy at the beginning of the present year, before the competing designs lately submitted to them were sent in. It is due, however, to Mr. Scott Russell to say that he had previously placed a design in the hands of the Admiralty; but with the details of this we are not at present acquainted. We have on former occasions spoken of the marked ability with which the construction department of the Surveyor of the Navy's office is conducted. One or two facts connected with the design for the singular ship now about to be built may be cited in confirmation of this view.

No less than fifteen designs were submitted to the Admiralty, by Messrs. Laird, Mare, Napier, Palmer, Scott Russell, Samuda, Thames Iron Company, Westwood and Baillie, and the Master Shipwrights of Her Majesty's dockyards. The only conditions stipulated for were that the ship should carry 36 guns, with certain men and provisions for four months, should travel at 14 knots per hour, and should be covered over a certain portion of its length with 4½ in. iron, backed by two feet of solid timber. All other elements, such as dimensions, horse-power, &c., were left entirely to the discretion of the designers. And strangely indeed did these gentlemen differ from each other in their ideas of what these undetermined elements were required to be! We are not at liberty to publish an analytical statement of the elements of the whole; but we may mention some of the extremes between which certain measurements of the several designs ranged. While the length, for example, of the least was 340 feet, the length of the greatest was no less than 430 feet. The breadths varied between 52 feet and 60 feet; the draughts of water between 21 feet 9 in. and 26 feet 6 in; the horse-power between 1,000 and 1,800; and the tons burthen between 4,887 and 7,544! In order to afford to the shipbuilder some clue as to the kind of structures proposed, we may also add that the proportions of the weight of hull per ton (exclusive of armour plates) to the burthen in tons, ranged between ·48 and ·86.

Now, the curious fact to be noted, and one which speaks so strongly in favour of the Admiralty constructors, is this—that their design, which was prepared, as we have said, *before* the others, turns out to be, in all her principal elements, as nearly as possible *a mean of all the other designs*. That is to say, if the *average* length of all the other designs be taken you get her length, which is 380 feet; if their average breadth be taken you get her breadth, which is 58 feet; if their average displacement be taken you get her displacement; if their average horses-power be taken you get her horse-power, which is 1,250. The average quantities obtained are not, of course, exactly her's in any case; but they are so nearly her's as to fully justify the view of the facts here presented.

These facts, it will be admitted, although they demonstrate nothing, serve nevertheless to indicate both the skill and the care exercised in the construction of our ships of war. It should be remembered, moreover, that the design in question was for a ship of an altogether novel character; on this account the department deserves the greater commendation. It would be well, indeed, for the country if in all our public departments the ability of the servants of the Crown were found to bear so severe a comparison with the private talent of the country with so much honour to itself.

GOVERNMENT ELECTRIC TELEGRAPHS.

THE electric telegraph is an agency which has not been altogether neglected by British Governments. Some small use was made of it during the late Crimean war; and in the more recent war in India it has unquestionably been turned to good account. But that any Administration has yet sufficiently comprehended the advantages which are to be gained by its means, or has sought to secure all those advantages for the country, we must entirely deny. Even as an auxiliary to the defence of this island, for which it is so eminently applicable, how little has it been yet adopted? The Government have under their own control one pair of wires putting them in instant communication with Woolwich, Chatham, Sheerness, and Deal; and they have another pair extending to Portsmouth and Gosport, from which a branch is led off to Aldershot; and these are all which belong exclusively to them. On the other hand, notwithstanding all our talk of coast defences, there is no direct electric telegraphic communication whatever between such places as Brighton and Portsmouth, Dorchester and Exeter, and so forth. Yet what could possibly be more necessary, in case of our coasts being menaced, than a continuous chain of telegraphs along our shores, connected at all points with the seat of Government?

If we turn our eyes to our possessions abroad, the facts are no more cheering. Up to this moment successive Governments have utterly neglected to put us in direct and independent telegraphic communication even with Gibraltar and Malta—important as those possessions are, and seriously as they would be endangered by some of those naval combinations of which we have lately heard so much! View the matter with as much lenience as we may, it is still manifest that submarine telegraphs to such places as these have become as essential to the security of our possessions as fleets and armies themselves, and that every hour of inaction in respect to them is attended by terrible responsibilities. It is little less than sheer fatuity to rely upon despatch vessels, and other like means of communication in this day, with an instrument like the electric telegraph in our hands. It is not less absurd to trust, as we are now trusting, to lines of telegraph which are as much in the hands of those who may any day become our enemies as in our own.

What appears to us to be necessary is, the instant establishment of a Government Department designed expressly and exclusively to work out and put in operation a system of electric telegraph communication, either apart altogether from commercial undertakings of a like nature, or in some prudent connection with them. A permanent staff of telegraphic engineers is henceforth, we submit, indispensable. Hitherto the practice has been to take private persons into temporary employment under the Government, and then to dismiss them whenever it has been thought convenient. We need not say that no kind of Government work can be done well or economically under such a system as this. There must be security, there must be permanence, in all such occupations; and in none more than that of which we are now speaking, because there is no occupation in which experience, and the skill which springs from it, are more indispensably necessary.

These suggestions are made in the earnest hope that something useful and reliable may be attempted in the shape of a Government organization without delay. We refrain from entering into considerations of cost, and matters of that kind, for fear of encumbering a very simple but, as we believe, important suggestion with needless details. The only hint of the kind that we will here venture to give is a recommendation to the Government to see, in laying down cables of their own, that efficiency is not sacrificed by excessive economy in the construction of their submarine cables. The cable from Malta to Corfu, for example, is much too fragile. One eminent electrical engineer informs us that £150 a mile should be spent on a cable for connecting our shores with our Mediterranean possessions, and that for this a cable excellent in all respects for the purpose could be produced. Another mentions a much lower amount per mile as sufficient. But whether it cost little or much this cable in particular should be made and laid down without delay.

SIR WILLIAM ARMSTRONG'S SPEECH.

SOME of our friends are expecting from us, we are informed, a somewhat severe comment upon Sir William Armstrong's late speech at Newcastle. But, unfortunately, we are not in the least angry with Sir William for what he said, and therefore we really do not see how we are to satisfy their expectations. It is quite true that Sir William fell into an error or two, and thus seemed to bear rather hardly upon us in one or two of his remarks. He makes, for example, a statement respecting the manner in which his gun is loaded, in which he very solemnly misrepresents us, as will be seen if we bring an extract from our Magazine by the side of his observations, thus:—

Sir William Armstrong's Speech, May 10, 1859.

"All the writers who have undertaken to give information upon this gun have spoken of a large screw working in the breech end of the gun, and pressing against a stopper for the purpose of closing the bore when the gun is loaded; but they all ignore the fact of that screw being a hollow screw, or they have misunderstood the purpose of its being so. There can be no secret about a process which is now daily performed; *the guns are both sponged and loaded through the hollow screw*, and it is a great mistake to say that the charge, or shot, or sponge can be introduced by the narrow slot or opening which is spoken of as receiving the stopper."

MECHANICS' MAGAZINE, *March 6, 1859.*

"We find that in the Armstrong Gun, as now made, *the large screw at the breech is formed hollow, and the charge is passed into the gun through it.* With this arrangement, the moveable breech-piece is only required to close the breech and receive the force of the explosion. Both the slot and the breech-piece are, therefore, smaller than they would require to be were the gun loaded through the slot."

Sir William does not speak of any variation in his practice in respect to this part of his gun, as he might have spoken. Again, he is certainly guilty of a little want of candour when he says the "stopper" is chained to the gun "to prevent the possibility of its being lost by casualty"—omitting to say that recourse was only had to this contrivance after one "stopper" had been blown away, and was never found more. Perhaps if Sir William had been disposed to speak all he knew and felt he would have also told his audience that but for the article in the MECHANICS' MAGAZINE he would never have opened his mouth in public at all about the con-

Digitized by Google

struction of his gun. But we could scarcely expect him to do this, as part of his business in making this speech may have been to lead the public on a wrong scent.

But these are considerations which we do not feel at all disposed to urge unduly. Sir William has spoken, and to a certain extent has spoken satisfactorily; and notwithstanding the points to which we have referred, we give him credit for having indulged in nothing splenetic or rancorous. It would be wrong to charge him with purposed misrepresentation even in the passage above quoted. For aught we know he may never have seen the particular paragraph in our Magazine which we have placed by the side of it. Sir William has had something else—and, we do not scruple to say, something better—to do for the last three months than to watch and scrutinize all that we and others have had to say respecting his invention. He is a man of action—pre-eminently so just now—and we, like all other writers, are, in our editorial capacity at least but men of words; and we have no desire to swell our work into undue importance. It has not been for the information, or even for the perusal, of Sir William, that we have written from time to time upon his gun—of which, we honestly confess, we are becoming somewhat weary. If we have enlightened those who, but for us, would have known nothing on this subject, we are quite content.

There is one very satisfactory feature about Sir William's speech, to which we would for a moment refer. Sir William is very confident of the powers of his gun and projectiles. He is an honourable man, and this confidence of his—making all due allowances for his position—is very re-assuring. Let us hope for the best.

ON TIMBER FOR SHIPBUILDING.

FROM the Paper read before the Society of Arts last week, by Mr. Leonard Wray, it appears that the aggregate tonnage (register tonnage, we presume) of the merchant shipping of the United Kingdom was last year 4,325,242 tons; and that of the Royal Navy is certainly not less than 1,000,000 tons more. When we consider that a very large proportion of these vessels are built entirely of wood, and that in twenty years at the farthest these magnificent fleets will have fallen into decay and disappeared, we may well view with interest any attempt to point out the means of increasing the durability of the materials of which they are composed, or obtaining fresh supplies for their constant reconstruction. In addition to the demands made for timber for these purposes, it appears, from an estimate which enters with considerable minuteness into detail, that ten times as much is required for the construction and repair of buildings, implements of husbandry, machinery, canals, bridges, docks, &c.

The proportion of this vast amount of timber material which could by any possibility be grown on our own soil is very small. It was found in 1816, when the demand was more limited and our stock of timber much greater than now, that the cost of timber imported was equal to the value of that grown on the soil; and since this time the deficiency in the home supply has been constantly increasing. We have seen ships standing week after week, and month after month, in our Royal Dockyards, while the purveyors were out in the forests endeavouring to find suitable timber, not only for stems and stern posts, and other principal portions of the frame, but even for the catheads from which the anchors were to hang; and any one may see by a visit to our dockyards with what difficulty the frames of ships now on the Government slips are obtained, and how greatly the amount of work on them is increased by the chocking and patching to which the builders have to resort. But we are beginning to be reconciled to this state of things, and to look forward with some degree of complacency to the time when our little island must cease altogether to supply her hearts of oak to furnish homes for her seamen. The bare possibility of such a catastrophe was viewed by our forefathers with horror. We find Henry VIII. passing stringent laws for the preservation of timber, "perceiving and right well knowing the "great decay of timber and wood universally "within the realm of England." By Elizabeth it was enacted that if any idle person cut or spoiled any wood or underwood, pales, or trees standing, and could not pay the satisfaction required, they were to be whipped. Receivers of such wood, knowing it to be so, incurred the same punishment. The 15th of Charles II., cap. 2, is an act to render that of Elizabeth more effective; and it enacts further punishment, because the destruction of wood tends to destroy the commonwealth. It is therein declared, that the officers of justice may apprehend even on suspicion of having carried, or in any way conveyed any burden or bundle of wood of any kind, underwood, poles, young trees, bark, or bast of any tree, gate, stile, post, rail, hedgerow wood, broom, or furze. For the first offence, on conviction, to be fined at the discretion of the justice, not exceeding ten pounds; or be sent to the house of correction for any time not exceeding one month; or be whipped. For the second offence the offender was to be sent to the house of correction for one month; for the third he was to be deemed an incorrigible rogue. In Scotland it was enacted in the reign of James I. that every heritor worth one thousand pounds of yearly valued rent, was to enclose four acres of land yearly, at least, and plant the same about with trees of oak, elm, ash, plane, willow, or other timber, at three yards' distance; and that all other heritors were to enclose and plant for the space of ten years in proportion to their yearly rental. Such enclosed lands were to be free from all taxes whatever, or quartering of horses, for nineteen years. Any person destroying timber not being their own property, were to pay £20 for each tree, or work six weeks for the person injured for their meat and drink only. Similar laws were passed for Ireland in the reign of William III., besides which it was required that 260,600 trees should be planted in the kingdom under the direction of the parish officers. And by George III. it was enacted for Ireland that any person who should have in his possession any timber tree, or any kind of wood, pole, stick, &c., and could not give a satisfactory account of how he became possessed of the same, or should stick up branches or shrubs of trees having the leaves on them, in any church, chapel, &c., holly, bay, yew, or laurustinus, and should be convicted on oath, should pay a fine not exceeding £5, or be imprisoned not exceeding six months.

In our own times we sometimes hear enthusiasts proposing to compel railway companies to plant oak trees along the lines, and to take other active means for staving off the threatened calamity; but people seem generally prepared to accept it with resignation. One cause of this probably is, that the comparative cheapness of foreign timber has brought it into very general use, and another that iron has taken the place of wood so largely. This latter cause holds with regard to ship-building timber, not only on account of the large present consumption of iron, but from our faith in its powers, and in the vastness of our store should we be driven to its nearly exclusive use.

Mr. Wray has, however, done well in the very interesting paper which will be found in another part of this Number, in bringing under the notice of ship-builders numerous valuable woods of which no use has hitherto been made. In addition to those given by him, we believe there is excellent timber, perfectly accessible, on the Atlantic seaboard of Brazil. There is in particular the *Secupira preta*, the growth of which is very crooked. Its weight is said to be from fifty-eight to fifty-nine lbs. per cubic foot, *i.e.*, slightly greater than that of English oak; the grain is curly, and not liable to split with fastening. It is used by the Brazilian Government in the construction of their vessels, especially in the curved parts of the frames. There is a frigate belonging to that government, called the Prince, now in use as a sheer hulk in the harbour of Rio de Janeiro, which was built of this wood forty years ago, and is reported to be in good preservation. The *Secupira preta* can be obtained in abundance at Alagoas, a place near Pernambuco, which is a seaport and a mail station. There is another very crooked and useful wood, called *Pao d'arco*, or arch wood, weighing fifty-five and a-half lbs. to the foot, and growing at Bahia, also on the sea-coast; and another, *Canella preta*, still lighter—about fifty and a-half lbs. to the foot—but equally durable, and grown on the southern portions of their seaboard. When we consider the cost of English oak—as much as 9s. per cubic foot of the largest sizes—its great scarcity, involving serious delays in the construction of ships, and much costly and clumsy patching, we think it high time that the Government took steps towards introducing some foreign timber for the frames of our ships-of-war. In the merchant service—as may be seen from Mr. Wray's paper—several kinds of foreign timber are admitted on equal terms with English oak. In the Government service it is not so. If we except Polish and Italian larches and Pitch-pine, which are occasionally admitted in small quantities, the *frames* of all ships built in the home yards are of English or Italian oak. We do not believe there is the least necessity for this—but that on the contrary, there are many and unanswerable reasons for discontinuing the use of oak timber of home growth, at least in the *frames* of ships, altogether. The feeling is, however, so strong in favour of English oak, that merchant builders still employ it largely, though in the majority of cases they pay dearly for it—for the timber which they can afford to use is small, and, to a great extent, spring-felled and unseasoned, and therefore subject to early and rapid decay.

It was our intention, had space permitted, to go into the question of the preservation of timber. We know something of the specifics which have been received into favour at different periods of our naval history, and we quite dissent from Mr. Wray's statement, that there are "simple, well-known remedies" for the prevention of dry-rot. That he is right, however, in predicting that dry-rot will make swift havoc in the newly-converted steam-ships we think probable, and we purpose taking an early opportunity for considering the question. In the meantime, if Mr. Wray, or any of our readers have any well-authenticated experiments on the preservation of the frames of ships by the application of antidotes to dry and wet rot, we shall be very glad to consider them, and to lay them before our readers.

OUR SILVER COINAGE.

IT has been demonstrated in previous articles on the state of the British Coinage that there exist great defects in it, and that the let-it-alone tendency of the public—so notoriously characteristic of the English—has permitted the

Digitized by Google

copper coinage especially to degenerate until it has become a positive nuisance. It is now our purpose to refer to the silver coinage of the kingdom, and to urge the Government to adopt such improvements therein as shall ensure the advantage of a circulation of legible coins, instead of the plain and polished discs which at present slip through the fingers of shopkeepers, and require a stretch of credulity to make one believe that they ever bore a Mint mark at all. It is, as we have previously stated, a fact that £10,000 are voted every year for the purchase of worn silver coins, and that pieces to that value, of the various denominations, pass yearly through the melting-pots of H. M. Mint, to be re-issued in the form of newly-struck money. It is equally a fact, nevertheless, that this renewal does not keep pace with the rapid deterioration constantly going on. The wear and tear of the hardworked sixpence, for instance, is enormous. It is the medium useful coin, which is allowed no respite from its duty, but is compelled to move unceasingly. The percentage of worn sixpences annually consigned to the Mint crucibles is far higher than that of any other coin.

So far as this amount of annual exchange goes, the evil of which we complain is met; but it is unfortunately a remedy quite unequal to the disorder. Our silver currency, in spite of the infusion of £10,000 worth of new coins yearly, is growing gradually worse and worse, and the bad consequences attending this state of things increase hourly. It is not of the direct material importance to the mercantile classes perhaps, that a worn *gold* currency—the value of whose individual units depends on exactness of weight—would be; but in other senses it is of most serious import to the whole community. To the counterfeit maker, a worn and defaced silver coinage is serviceable in the highest degree; as it is also to the utterer of his spurious productions. The imitation in other metals of defective money is comparatively easy to the contraband artist; whilst in company of each other true and false coins are difficult of distinction. A used-up coinage, in fact, invites fraud in a hundred ways, and is a positive curse to tradesmen and others among whom, principally, it circulates. It involves loss of time, and is a heavy pecuniary tax. We need not, indeed, particularise all the inconveniences arising from this evil; they are patent, and the thing is to suggest a cure.

It is a fact as well known to the Government as to ourselves, that during the last fifty years the trading and commercial transactions of Great Britain have increased enormously. They are happily, too, still increasing. It is plain then—without invoking Adam Smith or John Stuart Mill—that the gold, silver, and copper tokens of value we use must, as a consequence, have, say, treble the amount of duty to do that they had in the days of our fathers. The effects of heavy duty are only too plainly exhibited; and the images and superscriptions of George III., George IV., William IV., and even of our good Queen Victoria, are scarcely recognizable on the coins of their respective reigns. There is nothing for it but to make the supply equal to the occasion. Where one sixpence, for example, was coined in times past there should be now coined six; and, moreover, the age of all coins should be limited. There must be enacted a compulsory retirement clause for old half-crowns, shillings, sixpences, and threepennies—(groats are dying a natural death, for no more are to be struck)—after they have circulated for a certain number of years, say ten or twelve, their places being filled by new, intelligent, and intelligible candidates for public service. This would be systematic and practicable. Data might be obtained from the dates of the present silver coinage, as to the longevity in a useful condition of all denominations of coins, and the tenure of office of new monies would be made to expire with their fitness for active duty. It is no fanciful theory which we are propounding, but a necessary improvement, which ought, nay must be carried out.

If the Mint on Tower Hill be not of sufficient extent for effecting speedily the alterations, let its mechanical resources be augmented. Much, however, might be done, we are convinced, by the existing establishment in giving effect to our suggestion. The Mint, in days gone by, has done much when pressure required it, and its productive powers are now, as was shown previously, far greater. The entire silver coin in circulation in these realms represents a value of £12,000,000, or thereabouts, and the annual returns of the Mint show an average issue of about £340,000 worth. When, in 1816, it was determined to exchange the old silver coinage of the country for new, the Royal Mint appears to have done exceedingly well. It commenced striking the new coinage on the 16th of July in that year. By the 3rd of February, 1817, £2,500,000 worth was completed, and by the 4th of March following, £2,738,041. This consisted of the following kinds of coin:—

Half-Crowns	3,924,423
Shillings	36,025,750
Sixpences	17,848,025
Total	57,798,198

This labour involved many nights and some Sundays; but double the quantity might now be coined at the Mint without invading the hours of rest or of religious exercises. At that period it was resolved to effect, if possible simultaneously, the exchange of old for new silver, and the transaction did occupy actually only a fortnight. The whole of the old silver coinage was thus exchanged and withdrawn, and after the 1st of June, 1817, it ceased, by proclamation, to be a legal tender. The demand for coin continued urgent for several years after, and by the end of 1821 £7,500,000 worth was produced—a proportion of two and a-half to one of the old coinage. The old Bank of England tokens of 3s. and 1s. 6d. were next called in. In 1826, the Irish tenpenny and twopenny pieces, valued at £700,000, were also withdrawn, and replaced by pieces of the then modern mintage. The existing silver coinage of the United Kingdom, augmented by the small additions named above, consists of the products of the Mint from 1817 to 1826; and surely there can be no question that the time has again come for an entirely new issue. If so much work was done then, what may not be accomplished now? And how much more creditable to this great nation would it be to have a unique and beautiful coinage of silver—whether on the decimal plan or otherwise—rather than the present shabby, slippery, and meaningless collection of coins which betoken neither our high character as a State, nor our shrewdness as a trading community?

THE ENGINES OF HER MAJESTY'S SHIPS OF WAR.

BEFORE proceeding further with the Admiralty Report on marine engines than we last week went, we must add a few additional remarks upon those portions of it which then came under our consideration.

And, first, with regard to the Committee's observations on the preservation of the engines and boilers of Her Majesty's ships, it is, doubtless, of great importance that efficient means should be adopted to ensure the bringing home of the blame of any injury that may occur to machinery on board ship, through carelessness or neglect, to the proper person; and we naturally expected that such a Committee would, after possessing themselves of all the facts of the case, devise and submit a new and efficient remedy. Such has not, however, been the course adopted in this instance, for we find the very remedy which they suggest is now, and has for some time been in operation, not at Devonport alone, as the Committee seem to suppose by the prominent mention made of it, but at all the other yards also. The practice has been for the crew—*i.e.*, the engineers and stokers—when a vessel is about to be paid off, to open up the engines and boilers, and these men are detained until this work is done even after the other part of the crew has left, when that is necessary, so that the machinery may be ready for the examination of the inspector of machinery of the port. If this officer is competent to do his duty, we do not see any good reason for employing an officer from the factory, who has other matters requiring his attention.

In order to form a just estimate of the advantages of the Committee's suggestion respecting the best method of repairing the machinery, it is necessary to inquire whether it is intended that the present number of engineers and stokers of the steam reserve are expected to perform the additional repairs proposed to be done at the floating factory. If it be true that they are capable of doing more than is at present required of them, and if it is simply proposed to employ their time more fully and more profitably, there can be no doubt of the propriety of the proposed outlay for additional means. On the other hand, we do not believe that it would be a profitable way of employing a greater number than are required for the ordinary crews of vessels. Sea experience, no doubt, will give engineers a good knowledge of what is required in the working of engines; but it must also be borne in mind that, while this is gained, mechanical practice is generally lost, which is certainly of the highest importance, for it affects not only the quality but the quantity of work done. In repairing engines on board ship, those well acquainted with general work in addition to the working of the engines, are best adapted for doing such trifling repairs as occur; but it is well known that in large establishments, such as Government factories, the way to get work well and economically done, is constantly to employ each man on that kind of work at which he excels; and this can only be done where sufficient men and machines exist for embracing the great variety of work which presents itself.

We come now to that portion of the report which treats of "the construction and use of "steam machinery, and its adaptation to the "most scientific and economical principles"—a rather curiously-expressed title! This subject is divided into several different heads, the first being on high-pressure steam, which has occupied much of the attention of the committee. For many years high-pressure steam was considered altogether unsuited for marine purposes, more particularly in men-of-war; but during the Russian campaign, when there was so much demand for gun-boats, recourse was necessarily had to the high-pressure steam-engine, because there was not sufficient time to construct the more complicated condensing engine; and the experience thus gained afforded a favourable opportunity for forming generally an opinion on the merits of the high-pressure steam-engine when the boilers are supplied with salt water. The committee do not enter into particulars on the general question. They express, they say,

Digitized by Google

their own opinion relative to the advantages of condensing and non-condensing engines in an engineering point of view when they quote the following paragraph from Main and Brown's well-known work, "The Marine Steam Engine:"—

"The condensing engine is more economical in the consumption of fuel, because a vacuum is obtained on one side of the piston, and thus effective pressure is gained without any extra consumption of fuel, except that required to work the additional machinery, such as the air-pump, &c., connected with these engines; and likewise, since the steam used is of a lower pressure, and therefore at a lower temperature, the loss from radiation is less than that which occurs in non-condensing engines; also, since the feed-water comes from the hot well, and is consequently warm, an additional saving is effected. . . . . Therefore non-condensing engines will only be used where fuel can be readily obtained, and it is important to save space and weight. Hence they are used as locomotive engines on railroads, and are serviceable for very short voyages in steamers, especially for river navigation, because of the very small space occupied by the engines; but for long sea voyages, where a great store of fuel has to be taken on board, the extra space required for the additional fuel outweighs the advantages that would be gained by engines of smaller size."

The saving of weight alluded to in the passage quoted is, says the committee, not of much consequence, because although high-pressure engines are on the whole of less weight than condensing engines, still it should be remembered that high-pressure boilers are heavier than condensing boilers, and as regards the saving of space the advantage is only trifling. But the great and paramount evil of the high-pressure engine for marine purposes, and which the committee think ought to decide the question, is the necessity of using salt water in the boilers. The salt soon accumulates about the tubes, in spite of every care that can be taken, and full power can only be used for a very short time. The boilers themselves deteriorate before their due time, and the efficiency of the vessel as a man-of-war, that ought to be ready to act at a moment's notice, is lowered. Upon this head all the witnesses examined agree that they see no means of remedying the inconveniences that accrue from being obliged to use salt water in the high-pressure boiler. After making an experiment upon the Clinker gun-boat, at Devonport, by fitting her with a condenser, the committee recommend that when any of the high-pressure engines placed on board the gun-boats or steam-batteries require repairing, that a condenser and two air-pumps should be fitted. They do not, however, propose to disturb the present arrangement of exhausting up the funnel, in the event of its becoming necessary at any time to return to the use of high-pressure steam. Whenever boilers, however, may be required, they recommend that their construction should be so much modified that, without the least forcing of the furnaces, such a draught may always be obtained as will ensure a good supply of steam for condensation at 35 lbs. pressure.

To these suggestions the Surveyor of the Navy, replies that few at present would advocate high-pressure steam; for special purposes, however, it may have its value. The difficulties attending its use, as was expected, are entirely confined to the boilers; but these difficulties, although aggravated by having to use salt water, will it may be hoped, he says, be gradually surmounted, or at least in part. Be this as it may, the recommendation of the committee to convert all the engines of the gun-boats into condensing engines does not appear to him to be based upon sufficient experience. He says the Clinker has not been thoroughly tried; she is now under trial, and it seems proper to withhold the expression of any decided opinion one way or the other until sufficient and unquestionable facts are obtained for forming it; most assuredly, at present, it would be rash to offer one.

The committee next make some remarks upon the construction of the boilers for the steam-engine, as applied to marine purposes, upon which they write as follows:—"On board a steam man-of-"war there are peculiar circumstances that must "be attended to in the construction of boilers; "for instance, the space for them is not only "limited, but they are still further limited by "being necessarily below the water-line. Now "the great desideratum has been not only to "adapt the boiler to this limited space, but "further, to spare weight as much as possible; "and with this to put in a boiler that would "have the power, not only of generating steam "economically, but with sufficient rapidity to sup-"ply the engines. For this purpose what is com-"monly called the tubular boiler has been adopted, "and no doubt the reason it answers so well is this, "that thereby the greatest possible amount of "heating and grate surface is obtained. By it "the steam is quickly got up and quickly gene-"rated. But as tubes are not only expensive, "but apt to get out of order, choke up, &c., "many attempts have been made to dispense "with them. As long, however, as persons "projecting other plans for boilers have con-"formed to the limits assigned to them in men-"of-war, they have been failures, and for this "obvious reason,—they cannot obtain the same "amount of grate and heating surface as can be "done by the tubular boiler: the result is, they "have been unable to generate steam with the "required rapidity, and in the attempt have "injured their boilers. All this only proves, "that it must end in disappointment to sup-"pose that inventions can succeed that are op-"posed to recognised laws. Until new laws "and new powers of nature are discovered, we "must be satisfied to submit to those with "which we are at present acquainted. After all "the consideration that they could give to the "subject, the committee are decidedly of opinion "that the common tubular boiler is, of all "known boilers, the best adapted for men-of-"war, whether applied to high-pressure or con-"densing engines." The only other species of boiler that has come under their cognizance, and that has been actually tested at sea, at all likely to answer on board Her Majesty's ships, is, they say, Lamb and Summer's patent boiler: they are largely used in the mercantile marine, and are no doubt well planned; but after mature examination, the committee do not recommend them to the Admiralty for trial. "At the "same time it is but justice to state, that they "do not see any positive objections, nor could "it be thought a wasteful expense to give them "a trial." Meagre and contradictory enough all this, truly! The committee, when at Sheerness, examined the boiler patented by Admiral Tucker and Mr. Blaxland. After stating at some length the results of experiments which they instituted with the new boiler, and which they considered unfavourable, they say from what they have seen, and from and after all the inquiries they can make, "it has not been proved "to them that the patent boiler, either in its "present state, or with the proposed alterations, "is suitable for the use of the navy; the com-"mittee giving no opinion how far this boiler, "by alterations which as yet have not been "proposed, might be improved. If the present "boiler, either as it is, or as it might be made "by any improvements, becomes likely to be at "all more economical for the mercantile marine "than the present tubular boiler, the patentees "may be assured that it will immediately at-"tract general attention, as the committee can "state from their own personal knowledge, that "every plausible plan of improvement for steam "navigation is sure to receive immediate ex-"amination and trial by the northern great en-"gineering firms." All we can at present say on this subject is, that the decision of the committee—if it may be called a decision—is contrary to the experience of abler men than themselves.

When first the tubular boiler was introduced into the navy the tubes were made of iron; that metal has now been abandoned in all cases, and brass tubes are substituted, except where high-pressure engines have been placed in steam vessels, and in these cases iron tubes are now used. There can be no doubt that brass tubes are much better adapted for naval purposes than iron ones. One objection to iron tubes is that they deteriorate so rapidly when the vessel is laid up in harbour as to become unserviceable after long inaction. On this account the committee directed their attention to ascertain if brass tubes, with which the boilers of our high-pressure gun-boats had formerly been fitted, and which, on account of their leakage, had been removed, could not be made to answer in the boilers of these vessels. One of the committee, Mr. Nasmyth, proposed that bent brass tubes should be tried in the boilers of the Clinker high-pressure gun-boat. The same has been done, and these bent tubes are now on trial. On other points the committee report as follows:—

"From the evidence taken by the committee, it appears that in general the boilers supplied to our men-of-war are deficient in generating steam, and that full speed in consequence can only be maintained for a short time. Now the remedy to that defect must necessarily involve the whole question of the amount of space that can be allotted for the boilers, the committee therefore consider that they need not enter into further details, and that they do their duty by simply, and without comment, bringing the question before their Lordships. The difficulty of keeping the safety-valves of the boilers without leaking was also a point which was carefully considered, and the plan of a safety-valve proposed by Mr. Nasmyth, a member of this committee, was inspected, and as this valve has been found to answer on shore, and as the expense would not be greater than what is incurred by the present safety-valve, the committee deem it worthy of full consideration and trial. The committee do not think that sufficient attention has been paid in our men-of-war to the consumption of smoke. On board many of our mercantile steam-vessels there are several plans adopted, which, although they are quite simple, do appear, however, in some respects, to answer the purpose. One, for instance, which is much used at Glasgow, is boiler furnace fire-bars, by means of which a portion of air is heated in its passage to the furnace. It will be sufficient merely to recommend this plan to the consideration of the Government engineers. The obtaining a good draught in the engine-room and its vicinity, and preventing the hot air from spreading through the decks of a man-of-war, is most decidedly to be considered a desideratum. The committee went on board the Goliath, with Mr. Baker, the engineer of Chatham Yard, who showed them his invention of an apparatus for that purpose, and at the same time explained to the committee the mode by which it had been fitted on board the Goliath, although it was now withdrawn from that ship. Mr. Baker considered that it had answered the purpose intended, and that was also the opinion of Mr. Boulton, chief engineer of the Goliath, who transmitted to the committee a written account of the effect produced. The committee, whilst visiting some of our steam men-of-war, observed in one or two instances that platforms had been formed with gratings, and in one case iron plates had been so placed as to impede ventilation. The committee recommend that no gratings or iron plates that can in any way affect this important object be allowed to be placed in the engine-room or its vicinity, without the sanction of the proper steam authorities."

To all this relating to boilers the Surveyor makes no reply.

The committee next make special remarks upon the construction of marine steam-engines. "But they would first wish to draw attention,"

Digitized by Google

say they, "to a principle which, if carefully "kept in view, will, they think, prevent much "future difficulty and misunderstanding." What oracular revelation is coming now? Here it is:—"All the marine engines, whatever may be "the particular plan of construction adopted, "which have been lately made in this country "by the manufacturers of established reputa- "tion, when they come to be examined with "mathematical accuracy, and when their motion "has been analysed, have been found to give "out so nearly the same amount of power, that "the difference amongst them is hardly worthy "of consideration. Professor Airy, the present "Astronomer Royal, investigated the steam "engine known by the name of the 'Gorgon "Engine,' in this manner, and by comparison "with other engines, the results were found to "be as above stated. Now, the Gorgon en- "gine was almost an extreme case, as it pos- "sessed, in an engineering point of view, many "serious faults. From all this, your commit- "tee would conclude that the practical value "of marine steam-engines is not to be obtained "mathematically with any approach to exact- "ness. There are other and most important "points to be considered, and which materially "affect the problem; for instance, if the con- "necting rod is too short, the power is unequally "given out and may have a tendency to injure "the engines; simplicity in the construction of an "engine is another point of great importance; "and besides these, there are many other points "which are quite unnecessary to detail, but "must be carefully considered before any "just comparison can be made between engines "formed upon different plans."

On seeing such a mouse as this delivered from such a mountain, the Surveyor contemptuously says:—"No person having any knowledge of "theoretical mechanics ever doubted that 'the "amount of power' given out was necessarily "exactly the same; so nearly the same, that "the 'difference is hardly worthy of considera- "tion.' Mr. Seaward was perfectly well ac- "quainted with this elementary truth, and his "object in publishing Mr. Airy's approximate "calculation was simply to remove the preju- "dice of persons unacquainted with mechanics. "All the evils of a short connecting rod are of "a practical character, respecting the existence "of which there can be no difference of opinion; "it is admitted by all; but there is a great "difference of opinion respecting the amount of "the evils, some holding them to be serious, "and others of very little moment, the manu- "facturers whose forms of engines compel them "to adopt short connecting rods constituting "the latter class." We need hardly say that all science, as well as all common sense, is here on the side of the Surveyor.

After giving a page of general considerations, which it is not worth our while to reproduce here, the committee state, first, with respect to paddle-wheel engines, that the "oscillating" and "double cylinder" engines are the two best, the latter (patented by Maudslay and Field) especially where great power is required; and then they direct attention to the choice of an engine for driving the screw, which part of the subject they consider far more difficult, as it certainly is far more important. When screw propulsion was first introduced into the navy, say they, a great variety of engines of different construction were proposed, and, in process of time still further additions were going on, when it was resolved to adopt exclusively the direct action, that is to say, to drive the screw without gearing. During the period when this transition was taking place, from paddle to screw, and then from screw to screw without gearing, as might be expected, numerous mistakes were made in the construction of the engines to be used for the latter purpose. Indeed, in consequence of mistakes, and inexperience in this important point, the screw engines belonging to several vessels had to be taken out and broken up.

From the experience thus gained, the committee conclude that of all the variety of engines that have been purchased by Government for our screw ships of war, the following are so far superior to all others, that no engines of an older make should ever again be put on board. The engines to which they refer are:—1st. The single piston-rod engine, with the connecting rod attached direct to the crank shaft, and with a single flat guide. 2nd. The engine commonly known as the Trunk Engine, and patented by Messrs. Penn and Son. 3rd. The double piston-rod engine. They have no doubt that these three forms of construction are better suited for men-of-war "than any [other] modifica- "tions of the steam-engine that have as yet been "constructed."—(The committee do not write very good English; we have added the word in brackets in order to make sense of what they say.) The committee have arrived at the conclusion, that for very small engines, the single piston-rod engine, as adapted by Messrs. Humphreys, Tennant, and Dyke, (the first of the three classes just mentioned) is the engine best suited for the navy. "Indeed, it seems now to be almost "universally admitted," they say, "that the "single piston-rod engine is superior to all other "known engines for very small power; and it "may be noticed, that for the later built gun- "boats, two of our most eminent engineering "firms adopted that construction. The Com- "mittee are of opinion, that with our present "knowledge of steam machinery, that up to "300 collective nominal horse power, there is "no engine for men-of-war superior to the "single piston-rod engine, with a single flat "guide, and they are not prepared to say that "above that power its qualities may not be "found equally good. And that the trunk en- "gine, as constructed by Penn and Son, has "answered so extremely well, more particularly "where great power is required, that the Com- "mittee recommend that, with such improve- "ments in the details of these two engines, as "experience points out, they should be con- "sidered for the present the naval engine. . . . . "The committee have also made investigations "into the relative advantages of the arrange- "ments adopted by the different firms who have "constructed the double piston-rod engine, and "they are of opinion that in the general con- "struction, Messrs. Maudslay and Field's en- "gines are more simple than those of other en- "gineers who may have adopted this species of "engine; and they think also that the parti- "cular parts of their engines are more accessible "and more easily removed."

There is something very strange, and not a little suspicious, in the care with which the committee repeatedly limit the single piston-rod engine of Messrs. Humphreys and Tennant to very small powers, the more so as they have, after all, to admit, although with manifest reluctance, that "they are not prepared to say that above that power [300 H. P.] its qualities may not be found equally good." Now, this class of engine was first supplied by Messrs. Humphreys and Tennant to H. M. Ship Harrier in 1853. Since then they have supplied similar engines to the Brazilian, Portuguese, Turkish, and Russian Governments. For the last Government they set to work, in the summer of 1858, engines of 450 horse power on this plan, and have since, to our knowledge, received orders for engines of 600-horse power for a 120-gun ship of the Russian navy, with strict injunctions to make them of precisely the same arrangement. From these facts, as well as from other considerations, the remarks of the committee will be seen to be uncalled for, and calculated to prejudice the manufacturers of a very efficient form of engine, and one which is as applicable to large powers as to small.

Before concluding these observations upon the efficiency of steam-engines suited to the navy, the committee refer to the trials of men-of-war at the measured mile; and they consider a sufficient time is not always allowed to test the machinery. They believe that merely running a measured mile with a good supply of steam is no criterion of the real capabilities of the engines and boilers of a steam-vessel. They therefore recommend that in all trial trips of steam-ships, whether to test new engines and boilers, or after the old ones have been repaired, that besides running a measured mile, the trial should last at least six hours. "The speed, "consumption of coal, and, above all, the capa- "bility of the boilers to supply, without push- "ing the fires, steam at full power during the "whole time, should," say they, "be carefully "registered."

On the other hand, the Surveyor contends that no invariable rule on this subject could be acted on. Sometimes men cannot be spared without interfering with more important services to ballast a ship in order to bring her to a proper draught of water. Then the trial is deferred until she is brought forward for commission, or the first division of steam ordinary, and when this occurs in the winter months, the shortness of the days and the state of the tides frequently render it necessary for the ship either to leave and return into the harbour within six hours, or to anchor outside. The latter sometimes cannot be done without incurring serious delay in completing her equipment, as well as that of other ships. The committee, he says, are perfectly correct in their views, and if they had inquired into the matter would have seen that there was no difference of opinion as to the desirableness of lengthened trials, but that considerations such as above indicated, which probably the committee were not fully aware of, were, in the minds of those with whom the responsibility rested, of still greater importance.

The working of steam expansively is the next subject approached by the committee. It has long been a complaint, and a just one, say they, that, owing to the quick motion of the direct-acting screw-engines, the expansive gearing on board our men-of-war seldom acts for any length of time. It is found, either that they have to be removed on account of breaking, or from the apprehension of their breaking, the link motion, now generally adopted in the navy, is left as the only means of expanding the steam. In order, if possible, to obviate the above complaint, they, at an early period of their labours, directed their attention to the improvements that could be made in the direct-acting screw-engines, so as to enable steam to be used expansively with the greatest advantage. They soon saw, that with the direct-acting screw-engines, to work the steam expansively by means of cams was out of the question, and, after much inquiry and examination, they came to the decision of recommending that, to all new engines, and to those undergoing repairs, should be fitted what is called the "expansion flat grid-iron valve." This valve is worked direct from the shaft, with a separate eccentric. This arrangement has been largely adopted by the Glasgow engineers for the direct-acting screw-engine, and has been found to answer very well. "One remarkable "instance of economy, when this species of

Digitized by Google

"valve was used, came to their knowledge," say the Committee. "The pressure on the "safety-valve was 25 lbs., and the steam was "superheated, or rather dried, to the extent of "eight degrees; the length of the stroke was "three feet, and the steam was cut off by the "valve which is now recommended for the "navy, after it had entered the cylinder nine "inches. By these means the consumption of "coal was reduced to 2·5 lbs. for each indicated "horse power, and the speed of the vessel was "at times 13 knots per hour."

To this the Surveyor replies:—

"The improvements suggested in the construction of engines are two, namely, an expansive and a safety valve; the latter is now under trial, and the former has long been well known to engineers; but as its action, however modified, is not precisely what is wanted, while other constructions, although difficult to execute practically, are comparatively perfect in this respect, the gridiron valve worked by an eccentric has hitherto been adopted by very few engineers. There is doubtless the want of a good and simple expansion valve fit for quick-working engines, although it is practically of less importance now than formerly, for in the present day all such engines are fitted with what is termed a link motion, which, within certain limits, does all that can be desired, and beyond those limits goes far to meet the remaining requirements. Still a good and simple expansion valve is a desideratum, and it has occupied the attention of marine engineers for a long time. The fact that such a valve has not yet been designed, if we except that of Messrs. Maudslay, applied by them to some of their more recent engines, and which may, perhaps, be found practically unobjectionable, sufficiently shows that the difficulties are not easily surmounted. The one suggested by the committee, which has not the testimony of any eminent engineer in its favour, together with many others, have been fully investigated; its action, however, is admitted to be imperfect, and this is probably the reason why it has not been preferred to others. The desire is to obtain one which shall do all that such a valve is intended to do, and at the same time be simple and durable, but the particular valve now under consideration certainly does not appear to have that amount of merit in these respects as to render it advisable to make its use imperative."

The question of increasing the elasticity of steam by superheating it after leaving the boiler has been for many years a subject of experiment and controversy. In examining the various results which have been obtained by those who have given attention to the subject, there is nothing sufficiently definite, say the committee—and we quite agree with them—to afford an accurate estimate of the actual diminished consumption of coal with the same speed. As the results of all the inquiries that they could make, they submit the following remarks:—"Steam, as generated from the boiler, "whatever be its temperature, contains such "a quantity of moisture as makes it act in "some measure as a lubricator to the cylinder. "If, however, the steam were sufficiently su- "perheated apart from the water, so as mate- "rially to increase its elasticity, the consequence "of its drying qualities upon the working parts "in the cylinder would be such as to cause "either leakage or much friction. From this it "may be deducible that the superheating of "steam out of contact with water can only be "beneficially employed for the evaporisation of "any priming water carried out of the boiler "by the steam pipe. For the above reason, "the drying of steam, rather than its superheat- "ing, is a most important auxiliary to expan- "sion. . . . . From what has been here stated, "the reasons may be explained why the expe- "riments made on superheating steam have "given such different results. When the "boilers were indifferent, and there was much "priming water to evaporate, the gain from "using this process appeared large; with good "boilers, on the other hand, the gain appeared "small. If it is desired to secure to the navy "advantages of the process of drying the "steam, the committee would recommend an "addition to the steam space to be made round "the uptake of the funnel."

The Surveyor replies that for many years all doubt has vanished respecting the fact that considerable economy arises from the use of superheated steam, the degree of economy depending, as might be expected, upon the extent to which the principle is carried out, and upon the mode adopted for superheating the steam. But the late Dr. Haycraft's experiments, and others, as well as those recently made in the Black Eagle, and now being continued in the Dee, prove incontestably the fact of economy, which generally, at a moderate estimate, may be taken at about 20 per cent. "The "main points yet to be satisfactorily deter- "mined are," he says, "1st. Will no mischief "be done, or greatly increased wear occasioned "to the working parts of the engines in contact "with this kind of steam at a high temperature, "and whether, without greater care and atten- "tion than can be insured, is serious damage to "the machinery likely to happen occasionally? "2nd. What is the most practical mode of "carrying the principle into effective operation? "It may be sufficient here to say, that, on the "whole, great hopes are justly entertained that "very beneficial results will be produced, more "particularly in vessels which make long "voyages, and do most of their work under "steam. In ships of war, whose expenditure "of fuel is comparatively small, the saving "would, of course, be proportionally small; at "the same time, probably greater difficulty "and expense will have to be encountered in "carrying out the principle, owing to the neces- "sity of keeping the apparatus considerably "below the water's surface to be out of the or- "dinary reach of shot. The subject cannot now "be lost sight of, or fail to be prosecuted with "assiduity. All persons interested in steam "matters are fully alive to its importance, and "well acquainted with what is being done."

We next come to a very important-looking dissertation, "On the amount of steam power "that can, with most advantage, be placed on "board men-of-war;" but this we must leave for a concluding article in our next Number.

GREAT GUN-MAKING AT WOOLWICH ARSENAL.

At the Royal Arsenal, Woolwich, the practical experience gained by the officials in the gun factories is being put to the severest possible test. As if for the very purpose of making the managers and workmen perfect in the various duties pertaining to the art of heavy-gun-making, a two years' noviciate, as it were, has been permitted them; but now, in presence of the dark war cloud which overshadows this land as well as others, the hour of their trial has come, and that "with a vengeance." It is to be hoped that the rate of production, and the quality of the articles produced, may, therefore, be such as to justify the expenditure incurred, and prove the ability of all employed in the important task confided to them.

It is our present intention to further elucidate the operations necessary for the successful manufacture of these deadly weapons, and thus to supplement some previous information communicated to the public at large, first through our pages, and then through the press generally.

The qualities and characters of the irons most eligible for this kind of work have been already explained, as have the means of melting, and the kinds of furnaces best suited for the purpose. It may now be further stated that the patterns for the different-sized guns cast at Woolwich are themselves made of iron. They are put together in lengths, varying in number according to the dimensions of the guns to be produced, accurately fitted and bolted to each other by means of inner flanches. These iron gun patterns, indeed, greatly resemble the great guns of which they are the foreshadowers. The metal of which they are composed is about three-fourths of an inch in thickness. Much pain is taken in fitting the divisions together, and, when entire, they are carefully turned from end to end, then polished, and, in order to ensure their leaving the mould without tearing away the sand, are afterwards bronzed. The last process is highly important, and cannot be neglected without risk of failure. Supposing, then, that the smooth and well-finished pattern of a large gun is made ready for the foundry, by having "sight patches" and "vent fields" attached, and such other little arrangements made as would be essential in preparing for an ordinary casting, and which need not be described here, the moulding box is the next point to be regarded. At the Arsenal this may be said to be a very strong cast-iron pipe, made in two longitudinal halves, which are flanched outwardly from top to bottom. These flanches, which have been accurately "faced" to each other in the planing machine, are drilled for the reception of a large number of 1¼ inch bolts, and supplied at intervals with steel steady-pins. When it is said that the moulding box is a pipe, it may be explained that it is a pipe put together like the pattern, in lengths, and these lengths have outside latitudinal flanches perforated for holding bolts as in the longitudinal ones. These flanches are all faced in the lathe, and the alternate recesses and projections in them are turned to gauges almost mathematically. The greatest possible care is also taken to make the divisions of the box agree exactly in length with those of the pattern. To each half box a wrought-iron trunnion is firmly fixed. When the half boxes are united, a centre line through these trunnions would pass through the centre of the mould, whilst a centre line drawn vertically would pass through the centre of the box and mould. By these means facilities are gained for dealing with the mould, whether for the purpose of blacking, repairing, or alterations of any kind. Suspended in the slings by the trunnions, the whole affair may be moved in any direction by the application of the strength of a child. It has been said that the moulding box is strong; and much need is there that it should be so. It is composed of the best iron, and for a 68-pounder weighs five tons. Seeing that this womb for great guns is subjected to repeated heatings and coolings, and the frequent pressure of a solution of molten iron 17 feet in height and 28 inches in diameter at the base, it will be readily conceived that these precautions on the score of strength are not unwisely taken. In the pattern for a 68-pounder gun, there are seven lengths, and there are, too, seven lengths of moulding box to correspond. These, before the operation, are all detached, and are arranged side by side and opposite to each other, like a company of soldiers standing at ease. In commencing to mould the gun, each portion of the box is put over its corresponding portion of the pattern, great care being taken that they are centrally and truly so planed. This done, each division of the box with its enclosed division of the pattern is bolted down vertically to a cast-iron circular surface plate placed to receive it. The operation of filling the spaces—which circular detachable rings make equal—between the mould-box and pattern with prepared sand is now commenced. This sand is composed of natural sand from the neighbourhood, coke dust, and occasionally, for the breech end of the mould, of cow hair. The proportion of coke dust to sand as now used is as 1 to 12. The whole is incorporated in a pug mill. This composition is rammed "home" in each case with a narrow-headed rammer very carefully, and it is fed in small quantities. When one of the seven receptacles is filled with the sand or loam, an iron straight-edge is passed over the upper surface to make it true with the flanch. The circular plate at its base naturally performs a similar task, and both ends are thus made even. All the seven

Digitized by Google

parts being treated in this way, a travelling crane suspending a beam of wrought-iron with two pullies placed at the same distance from each other as the trunnions, and furnished with endless chains, lifts them one by one from the patterns, and suspends them for examination and "blacking." The Woolwich blacking is made of the very best oven-burnt coke (ground as finely as possible under heavy runners), charcoal blacking, and clay-water, mixed to about the consistency of paint, and with paint brushes it is applied to the moulds. Drying is the next part of the performance, and this is effected in stoves about 20 feet long, 9 feet bread, and 8 feet high, and covered by brick arches. These stoves are important auxiliaries to the successful manufacturing of heavy guns, and next week, when this paper will be concluded, a further account of their nature and construction will be given.

(To be concluded in our next.)

Proceedings of Societies.

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY.

May 3.—W. Fairbairn, F.R.S., &c., President, in the chair. The Librarian, on behalf of the widow of the late distinguished Professor Jobert, presented to the society about 100 copies of that gentleman's "Philosophy of Geology," and an equal number of his "Ideas," partly bound and partly in sheets.

"A Notice of the Geology of the Australian Gold Fields," by W. S. Jevons, Esq., late of the Sydney Mint, communicated in a letter to Professor Roscoe, was read.

Mr. H. M. Ormerod produced two specimens of iron used in building, which had both become oxydized so as to injure the buildings which they had been used to strengthen. One, an iron cramp, taken from the north-west buttress of Manchester Parish Church, about one foot long and three-eighths of an inch thick. This had become treble the thickness by rust, and had split the buttress, in the centre of which it was inserted, lifting about twelve feet of wall. It had been inserted about ninety years since. The other, a small wedge, from the steeple of St. Mary's Church, in Manchester, about three-eights of an inch thick at the broad end originally, but now seven-eighths. These wedges had lifted all the stones which they were meant to keep in their places, splitting some, and allowing all the rain to penetrate. The steeple was erected about 1756, and the upper part has now become so ruinous and dangerous from the original faulty construction, and the expansion of the iron cramps and wedges, that it is being taken down, pursuant to notice from the city surveyor.*

A paper, communicated by Dr. Smith, was read by its author, Dr. Roberts, Physician to the Royal Infirmary, "On the Effect of Food on the Reaction of the Urine."

Dr. Joule having taken the chair, a paper was read by the President, W. Fairbairn, F.R.S., entitled "Experiments to Determine the Effects of Different Modes of Treatment on Cast Iron for the Manufacture of Cannon."

After commenting upon the importance of the treatment of iron in the manufacture of cannon, and on the want of knowledge upon this subject, exhibited in the failure of many of the guns employed in the Russian War, the author proceeds to describe the processes usually adopted in the foundry for the improvement of iron, under the heads mixing, remelting, and prolonged fusion. The value of remelting and mixing iron has long been recognised, and their effect in increasing the tenacity of the metal has been fully demonstrated by experiments. Lately the influence of prolonged fusion had also been the subject of inquiry, and the conclusion had been arrived at that a continual exposure of liquid iron to an intense heat augments the cohesive powers of the iron in proportion to the duration of the exposure, up to some not well ascertained limit where the opposite effect begins to be produced, and the iron deteriorates.

The author then proceeds to narrate the results of some experiments in which he was engaged in 1855, on the improvement of cast iron ordnance. Five twenty-four pounder guns were cast of a carefully selected mixture of the following qualities of iron:—

Blaenavon, No. 1	2.2 per cent.
Blaenavon, No. 2	16.7 „
Blaenavon, No. 3	28.9 „
Lilleshall, No. 2	35.5 „
Pontypool, No. 3	16.7 „

In casting these guns it was sought to determine the effect of various modes of treatment in the foundry: hence,

Gun A was cast in the usual way, with 3 feet 6 inches head.

Gun B was cast from the air furnace, of iron remelted once before casting into the mould.

Gun C was cast from the cupola, with desulphurized coke.

Gun D was cast from the air furnace in the usual way, under a pressure of 17 feet 6 inches of head.

Gun E was cast from iron remelted once, and then run into mould, under 17 feet 6 inches head of metal.

These guns having been bored and turned, were conveyed to Woolwich Marshes, and subjected to proof by firing, beginning with the usual proof charges, with a gradually increasing quantity of powder and weight of shot, until the gun burst. The result of these proofs is exhibited in the following table:—

Gun.	Number of rounds fired.	Total quantity of powder used, in lbs.	Total weight of shot fired, in lbs.	Total number of wads used.
A	33	364	3,120	91
B	32	350	2,952	90
C	17	150	1,152	43
D	31	336	2,784	89
E	33	364	3,120	91

From this table it will be seen that, whilst the gun cast with desulphurized coke from the cupola exhibited comparatively a great inferiority,* the guns E and A, one of which had been cast in the ordinary way, and the other with remelted iron, under pressure, exhibited very high powers of resistance. The results thus obtained were further confirmed by experiments upon the tenacity and density which gave the following mean results:—

Gun.	Density.	Tenacity in lbs. per sq. in.
A	7.2105	28,516.
B	7.2325	27,219.
C	7.0863	18,101.
D	7.2032	25,954.
E	7.2441	28,516.

After discussing the result of these experiments, in some respects anomalous, gun A being a peculiarly fortunate cast, it appeared that the other guns were improved by the remelting and pressure of head, so as to give the best result with E, which had been subjected to both these processes. In conclusion, the author alludes to experiments on guns cast with a core, and expresses his belief that the great practical difficulties which beset that process must prevent its application, although theoretically calculated to produce guns of greatly increased strength.

THE GEOLOGICAL SOCIETY OF LONDON.

May 4.—Prof. J. Phillips, President, in the chair. M. Moggridge, Esq., Swansea; F. J. Mitchell, Newport, Monmouthshire; and T. Wright, M.D., Cheltenham, were elected Fellows. R. F. Williams, Esq., P. D. Tuckett, Esq., and J. Phillips, Esq., were admitted. The following communications were read:—1. "On the Ossiferous Cave, called, 'Grotta di Maccagnone,' near Palermo." By Dr. H. Falconer, F.R.S., F.G.S. 2. "On the Jurassic Flora." By Baron Achille de Zigno. Communicated by C. Bunbury, Esq., F.G.S. 3. "On a Group of supposed Reptilian Eggs (*Oolithes Bathonicæ*) from the Great Oolite of Cirencester." By Prof. J. Buckman, F.G.S. 4. "On some Sections of the Strata near Oxford." No. I. By Professor Phillips, Pres. G.S.

MEETINGS FOR THE ENSUING WEEK.

MON.—*Royal Agricul. Society*, General Meeting at 12 a.m.
Royal Geographical Society, Anniversary, Monday, May 23rd, at 1 p.m., when the Gold Medals will be awarded to Captains Burton and Palliser, by the President, Sir R. I. Murchison, who will then deliver his Address on the "Progress of Geography." The Dinner will take place at the Freemason's at 7 p.m.

TUES.—*Zoological Society*, at 9 p.m.
Inst. Civil Engineers, "On the manufacture of malleable iron and steel," by Henry Bessemer, Esq., at 8 p.m.
Royal Inst., "General facts and leading principles of Geological Science," by John Morris, F.R.G.S., at 3 p.m.

WED.—*United Service Inst.*, "The acclimation of European Troops in Indian Hill Stations considered in relation to the increasing rates of their sickness and mortality on removal to the plains for service," by Dr. Birch, F.R.G.S., at 3 p.m.
Society of Arts, "On the application of the Conic Sections in Architecture; illustrated by the Obelisk, with some history of that feature of Art," by Mr. John Bell, at 8 p.m.

THUR.—*Society of Antiquaries*, at 8 p.m.
Royal Society, at 8 p.m.

FRID.—*Royal Inst.*, "On the Ossiferous Caverns and ... sures of Devonshire," by William Pengeley, Esq., at 8 p.m.
United Service Inst., "The application of Statistics to Naval and Military Matters," by W. Farr, Esq., F.R.S., at 3 p.m.

SAT.—*Royal Inst.*, "On Modern Italian Literature," by J. P. Lacaita, Esq., at 3 p.m.

THAMES GRAVING DOCKS.

THE report of the directors of the Thames Graving Dock Company announces the successful completion of the undertaking for which the company was formed in April, 1857, and states that Mr. Edwin Clark's patent arrangements have fully realized the expectations entertained of their efficiency. Up to the end of last month eight ships, varying in burden from 500 to 1,800 tons, of wood and iron, sailing ships, paddle-wheel and screw steamers, have been raised, floated, examined, and repaired, with a degree of celerity, security, and ease, utterly unknown under the old system of graving docks. The pontoon recently launched has been employed in raising and floating several ships, and fully answers all the uses for which it was intended. Another will shortly be launched, and four more are in course of construction. During their experimental operations the directors experienced the want of a permanent establishment in the docks, ready to repair the ships sent to them to be lifted and examined. They have met this difficulty by letting one slip and the one available pontoon to the shipbuilding firm of Messrs. W. Rose and Co., of Wapping. The report of Mr. E. Clark, the engineer, states that the works are now complete in every respect. Ten vessels have been raised and repaired, and many of them floated into the shallow docks for that purpose. This number includes timber, screw and paddle steamers of various descriptions, varying in weight from 500 to 1,800 tons. The operation has not occupied more time than was contemplated, a vessel having been raised, examined by Lloyd's surveyors, and again launched in one hour and a quarter. In no case has any vessel been subjected to the slightest degree of unequal strain, and all the shipowners have expressed themselves highly satisfied with the facilities afforded them. We regret to state that we have grounds for questioning the perfect truth of some of these statements.

MATERIALS FOR PAPER MAKING.

AT the Exhibition of the Society of Arts, now open, a case containing eight specimens of vegetable fibres prepared for paper making is exhibited. It contains: 1st. Straw deglutinated and "fibred." 2nd. Straw deglutinated, fibred, and half bleached. 3rd. Straw deglutinated, fibred, bleached, and reduced to pulp. 4th. Sugar cane, trath, or megos deglutinated, fibred, and bleached. 5th. Gunny bag or old jute deglutinated and bleached. 6th. New jute deglutinated, bleached, and reduced to half stuff. 7th. An Asiatic red bark, *i.e.*, the bark of the Sterculia ulens, deglutinated, fibred, bleached, and reduced to half stuff. 8th. Vegetable silk, deglutinated, fibred, and bleached. The three first of these articles are not exhibited as novel articles for paper making, but to show that, by the process to which they have been submitted, they are rendered strong and fibrous, and therefore much better suited for making good and durable papers—far better than the straw papers which are usually found in the markets at present, whilst the evil of preparation is much less than the evil of preparing straw for such purposes generally. The 4th, 5th, and 7th specimens are exhibited as articles well suited to supply the place of finer rags in making papers of superior quality at a lower price than fine rags, which are now every day becoming scarcer in the market, and therefore will not long continue to supply the present increasing demand for paper for writing and printing—a demand which will assuredly go on increasing as education is extended among our growing population. No. 6 is exhibited to show that the gunny bag or old jute is for the use of the paper maker as well suited as the new article. No. 8 is exhibited to show that when it becomes a worn-out article it will be used by the paper maker, which the ordinary silk will not be, and therefore it is calculated in time to become a useful addition to our supply of fine rags.

* After grinding and polishing the iron rust, it presented a black iridescent surface of almost metallic brilliancy, and similar, in appearance, to Elba ore. It was capable of being made into a magnet of considerable power and retentiveness.

* Considerable want of uniformity is observable in iron melted in the cupola, unless retained for some time in a state of ebullition at a high temperature. This will account for the comparative weakness of the gun C, which, under different treatment, would have been greatly improved by the use of desulphurized coke, as was found to be the case in former experiments.

THE INDUS STEAM FLOTILLA.

IT must have been a proud thing for Mr. Scott Russell to stand the other day upon the deck of what is probably the best light-draught steamer ever built in this country, and, looking along the river upon the magnificent Great Eastern, to know that the forms of both were the products of his own brain. Indeed, the relation in which that gentleman stands to naval architecture in this country has long been a very proud one. It is stating nothing more than every cultivated shipbuilder knows when we say that no other naval architect of the present century has ever both attempted so much and failed in so little as he. Never hesitating to push his art forward by all the means which a daring faculty of invention has suggested, he has nevertheless been singularly successful in preserving in his vessels all those qualities which are essential to their security and to the confidence of the ship-owner. The beauty of his vessels is sometimes questioned; but nothing short of blind prejudice could doubt their general excellence. Such results could only have been obtained by a felicitous blending of faculties which but seldom indeed meet in the same individual.

It is not our present purpose, however, to dwell either upon naval architecture, or upon Mr. Scott Russell's influence upon it; but rather to pen a few remarks by way of accompaniment to the engraving which we this week present to our readers, and which they will, we doubt not, highly value. It is an illustration of the vessel the trial of which was lately noticed in our columns, and has been very carefully lithographed from a proof taken from a copper plate engraved with the well-known and admired skill of Mr. Lowry. Its fidelity, even down to the minutest detail, may be confidently relied upon. With a plate like this before him, the shipbuilder will need no verbal description.

The design of the vessel before us was selected from many which were submitted to the Scinde Railway Company, being considered the most suitable of all for peculiar navigation of the Indus. It was founded upon data supplied by Mr. Yarrow, the engineer of the company. It must be acknowledged that two feet is an exceedingly light draught of water for a steam-vessel, and that more than ordinary skill was necessary in order to construct a fast vessel that should draw no more than that; yet that was the amount fixed upon as the maximum for the Indus steamers, and Mr. Russell has fully succeeded in overcoming all the difficulties of the case. The length of the vessel over all is 200 feet, breadth 38, draught of water at the time of the recent trial 1 ft. 10 in. As a passenger boat, and with average cargo, her speed exceeds 13 miles an hour, and with boats containing 500 tons of cargo in tow she can be depended on to average eight miles an hour on the Indus. The hull is constructed in a peculiar manner, in order to carry the weight and sustain the propelling action of large machinery. Two longitudinal wrought-iron girders run the whole length of the vessel, rising nearly ten feet above the deck, so as to form the bulkheads of the deck cabins. These girders constitute the main portions of the hull, and are applied in a manner peculiar to Mr. Scott Russell, and which he has already employed in the construction of the Great Eastern and other vessels where great strength and great length are necessary. The engines are of 120 nominal horse-power, but work up to more than 600. They are constructed upon Mr. Russell's patent three-cylinder principle, which was fully described and illustrated in this Magazine a few weeks since.*

We hear much of the light-draught steamers of America; but there is good reason to doubt if anything so well-contrived as this Indus vessel exists in the United States, all the circumstances of the case being considered. If our excellent cousins fancy they have anything superior to it, we hope they will do us the favour of sending it over. At any rate, Mr. Russell has succeeded in solving a very difficult problem in a very satisfactory manner, and has provided the means of adding largely to the commercial prosperity of our Indian Empire.

THE EFFECT OF THE INTRODUCTION OF THE ARMSTRONG GUN ON NAVAL ARCHITECTURE.

BY CAPTAIN J. GARDINER FISHBOURNE, R.N.†

I AM to show the necessity for a change in the present practice of naval architecture, in order that the country may obtain the full benefit of Sir William Armstrong's admirable invention. I propose to give, 1st, a sketch of the advantages it affords; more would not be proper. 2nd, a sketch of the practice of naval architecture that it is requisite to change. The great results obtained from rifle muskets, both as to range and precision, made the adaptation of breech-loading cannon a necessity that could not long remain unsatisfied. It seems a guarantee for the continuance of our prestige, that no sooner is there a want really felt than genius and skill start up to afford an ample supply. The principle on which Armstrong's gun is constructed is so correct, and the details of its carriage-slide and missiles so simple and complete, that it will be the work of but a short time to satisfy the most incredulous as to their great value. The precision of fire attainable by it is alleged by competent authority to be fifty times greater than that obtained with the ordinary service-gun throwing solid shot of equal weight, each at a distance of 1,000 yards; indeed it is six times more accurate at 3,000 yards than the ordinary smooth-bore gun at 1,000 yards. To arrive at the accuracy of fire, range, and penetration realised, there have been used, 1st, elongated shot, by which, while equal momentum has been preserved, a very great reduction of the area of resistance has been effected. 2nd. By the rifle principle rotatory motion is communicated to the shot, by which, together with the right adjustment of the centre of gravity, and of the form of its anterior surface, the longer axis during the flight is preserved parallel to the axis of the gun, and great accuracy attained.

Hitherto, owing to the extreme difficulty, amounting almost to an impossibility, of casting homogeneous spherical shot, the centre of gravity was never found in the centre of the sphere, hence the shot in their flight were diverted from their proper paths, by which great disparities in range and deviation in direction were occasioned. By using a ball which fills the cylinder of the gun much cause of error is avoided. The ordinary spherical shot not filling the cylinder, in its motion it strikes one part or the other uncertainly, and becomes proportionably uncertain both in its direction and range. Everything which contributes to remove the causes of deviation tends to increase range, and increase of range tends to precision of fire; as, under such circumstances, less elevation is required for a given distance, the shot travels nearer the earth, and will strike objects of a moderate height that intervene.

Greater Safety.—The superior principle upon which this gun is constructed is a greater guarantee against its bursting; and it cannot reasonably be doubted but that loading at the breech will be attended with less danger from accidental explosion of charges; also, the danger to men (increased by the introduction of rifles) while loading at the muzzle will be avoided, and the occasional danger from fire left within the gun is disposed of by the use of a moist sponge.

Greater rapidity of fire—by which I mean the delivery of *effective* fire.—I use the expression *effective* advisedly, as a comparison as to the rapidity of firing without aiming at an object has been sometimes absurdly instituted. Armstrong contemplates firing four times in a minute. The facilities for delivering a rapid fire from this gun are great, because the distance which the cartridge and shot have to travel is much less—because the position of the loader is more advantageous for effecting his object, which, in comparison of muzzle-loading, is enhanced in proportion to the weight of the shot used; and, should an accident occur to the rammer—not uncommon to the long handles of those used for smooth-bore guns—this can be loaded by hand The gun has not to be run up each time, nor does it require to be pointed each time, unless the object or battery be in motion; even then the facilities for pointing are greater than in the ordinary guns. The power of delivering a rapid fire may not with propriety be estimated for a limited period, but rather be connected with the adaptation for comparatively continuous fire. As the charges are considerably less than half those ordinarily used, and, as the moist sponging and the rush of cool air from the open breech tend to keep the gun cool, the fire could be continued very much longer than from the ordinary guns.

Economy.—In estimating this, owing to its increased efficiency, it would be impossible to set off the cost of gun against gun, but rather against the cost of the number to which, owing to greater range, precision, and power of dispersion, it in effect is equal to.

Convenience.—This hardly expresses the increased value of this gun due to its greatly reduced weight; owing to which it admits of easy transport—field-pieces and guns for battering purposes being much less than half the weight of those ordinarily used. Great as are the advantages stated, it possesses greater for ships' batteries, for reasons which I purpose giving hereafter, proceeding first to give a practical illustration of the comparative advantages before alluded to. Lieutenant Dahlgren (United States Navy) mentions that at 260 yards each of ten shot fired from a 32-pounder, were included in four feet square of the screen aimed at, while of ten shot fired from the same gun at a screen 40 feet long by 20 feet high, and distant 1,300 yards, only three struck: that is, at five times the distance, though the target was increased fifty times, only one-third of the shot fired hit it. One hundred shot fired from Armstrong's gun at a target nine foot square, and distant 1,500 yards, struck nearly every time, knocking it down several times; after which it was fired at, still on the ground, and was hit several times; and yet all this occupied but two and a quarter hours, and the temperature of the gun at the termination was only 150°. Although this illustration tells very much in favour of the latter gun, such estimates, founded upon mere "hits" of large targets, by no means mark its immense superiority; for, as the value of guns is in proportion to their power of throwing shot into embrasures, of hitting a narrow and definite line for

† Slightly abridged from a lecture recently delivered at the United Service Institution, on "The Effect of the Introduction of Rifled Cannon on Naval Architecture."

Digitized by Google

breaching purposes, or of throwing shot into ships' ports, or of hitting them "between wind and water," so must estimates of their comparative value be drawn from the precision with which they strike *small* objects. The additional value of those described for ships of war arises from the fact of their being so much lighter, and from the small amount of their recoil (*practically none*), owing to which they will not require ships of such great breadth. This involves very great general naval efficiency and economy. The small external diameter, particularly at the chase, will admit of smaller ports; no inconsiderable advantage should ships' sides be covered with plate-iron. It is not my purpose to state all the advantages to be derived from this admirable invention; sufficient has been said to show the necessity for its introduction, and that doing so at an early period will cost the country much less. The efficiency of the navy also will be increased in proportion to the promptness with which it is applied, provided its value is not rendered nugatory by an absence of adaptation in the forms of the ships. The wonderful success described has been obtained by an accuracy of detail that some, who pique themselves upon being practical, I say not how correctly, would, *à priori*, have characterised as theoretic and crotchety, but which nevertheless has proved to be eminently practical.

If the practice of naval architecture is to be progressive, if, in fact, we are to elevate it to the rank of a science, which it is now only in part, whatever professional architects may say to the contrary, we must follow out our observations and experiments with similar accuracy of detail. The present practice, for war purposes, bears the relation to what it ought to be, that the service ordnance does to Armstrong's guns. Not that ships may be designed that shall sail or steam fifty times faster than at present; but they may be made some indefinitely large quantity more valuable for war purposes—it may be, in some cases, fifty times more so, and at less cost.

It has been said that the introduction of steam and progress of scientific discovery necessarily entailed rapid and extensive changes—say, rather, that this progress has found us pursuing an unscientific course. Science moves with measured strides, like "coming events casting their shadows before;" her every step is the subject of law, and none can follow, however distant, but must be so far in harmony with her designs as not to need at any time to have recourse to more rapid or to radical changes. Thus, the lengthening of new ships' bows ought not to have been required, as the long bow should have formed part of the original design, its value having been proved full fifteen years previously; indeed, the longest adopted are still shorter than that which science would dictate.

We condemned a whole fleet of ships; and yet, whatever were their defects of size, for correctness of design, and for adaptation to the purpose for which they were intended, as a whole they are unsurpassed, nay, unequalled by their successors. Let me not be misunderstood. It is true that the latter were larger and, in the ordinary sense of the term, finer ships; yet, had we adhered to the principles contained in these earlier forms, we should have more efficient ships than we now possess.

Again, when steam-power was introduced, the authorities had embarked at a cost of three millions in building another fleet* of ships of great proportionate breadth, and of a general form that was opposed not only to the authority of the best standard treatises on the subject, but to the accumulated experience of ages; nor was it the introduction of steam that opened our eyes to the fact that in building such vessels we were steering vastly wide of the track which science would have dictated—that fact was made patent by the sailing squadrons of 1846 and 1847, which led to the abandonment of the extreme peculiarities of the forms alluded to. No doubt, however, the expensiveness of steam as a motor forced upon reluctant minds the fact, that ships of greater proportionate length than had ever been adopted were more easily driven, whether by sails or steam. Long before that, however, merchant sailing-vessels of this and other countries had yielded abundant proofs to that effect. Why we should not have drawn inspiration from such sources it is difficult to understand.

But, while the discovery that we were far wide of the proper track led to a decided improvement in our practice, it did not lead us to the re-adoption of those sounder principles of design which characterised some of the older models, both French and English. This is attributable in some respects to the same cause as that which led to the adoption of great proportionate breadth and rising floors—viz., the undue importance attached to great speed, and the misapprehension how that quality might best be obtained. This had the effect, not yet wholly got rid of, of obscuring what one might have supposed to have been very obvious—viz., the fact that it is impossible to exaggerate one quality in a ship without proportionally diminishing one or more others.

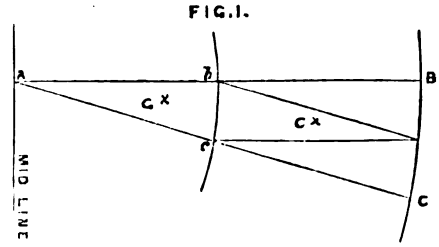
It is too much the habit of professional men to assume that laymen cannot understand these things; they, therefore, deliver their opinions *ex cathedra*, and afford us no proof: on the contrary, I profess to be a sailor, and have long acted upon the principle, that, if I could not explain to an intelligent mind or indeed educate an uninstructed one up to a comprehension of any point connected with my profession, the fault was in myself. Now, what we require is, that naval architects will cease to obstruct those who are searching for truth, acknowledge—what all are beginning to discover—that there is an amazing amount of ignorance on the subject of naval architecture even amongst those who have studied the subject most, and join us in our search. Enough of time and money has been wasted in experimenting without system, and too often in violation of principles; no plans should be accepted without proofs of their correctness, or without being tested by the application of carefully-arranged statistics.

As our information in some respects is only comparative, we may thus inquire what the fact is as respects some of our modern ships of war. If there is an adherence to principle in their designs, we shall be able to trace a consistency throughout—that is, a definite relation in the proportions of one dimension to another, as length to breadth, depth to breadth, and in screw vessels between the area of screw and its depth of immersion, and the area of greatest section, or only such a departure as was indispensable, and as did not mar the design.

There are two things which have always been held as ruling the proportion of breadth to be given to vessels of war—a sufficiency to obtain stability and a good platform for guns. The precise quantity necessary has been for some time a vexed question, therefore an opinion from any one cannot be deemed sufficient. Nevertheless, what is not a proper quantity may be arrived at, and much fairly inferred from that. *Ceteris paribus*, stability increases as the cube of the breadth, the moment of sail or power that produces inclination not increasing in so rapid a ratio, consequently the larger the ship the less is the proportion of breadth required to produce a sufficient amount of stability.*

When a vessel inclines she immerses a prism on one side and emerges an equal one on the other; by the volume of these, and by the distance of their centres of gravity from each other, is a vessel's stability compared with that of another. Suppose fig. 1 to represent one of these prisms for each of two vessels, one double the breadth of the other; from this it will appear that *A b c* is only one quarter that of *A B C*, and *G* is only half the distance from *A* that *C* is, therefore the effect of the larger prism is equal to $4 \times 2 = 8$;

FIG. 1.



in other words, the stability of a vessel of double the breadth is eight times that of the smaller; but 8 is the cube of 2.

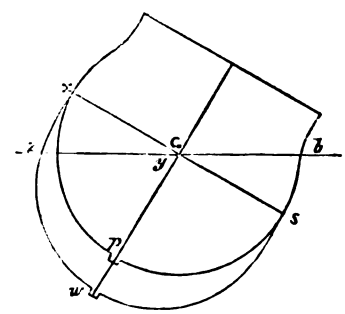
The following dimensions—

	Length.	Breadth.	Ratio of Length to Breadth.
	feet.	ft. in.	ft. in.
Marlborough...	245	61	4 0
Renown.....	245	55·6	4 ⅜
Racoon	200	40	5 0

show that the smaller vessels have the least proportion of breadth, which is the reverse of what adherence to the law above described would require. Nor can it be said that this arose from the necessity for a wider battery in the larger vessel, for the Racoon carries guns on her broadside of equal length and calibre with those carried by the Marlborough.

There is another dimension—viz., the depth, which exercises an important influence on the properties of ships; this, also, has been treated as if there was not a proportion of it to breadth that was more correct than any other.

FIG. 2.



If we suppose Fig. 2 to represent the cross section of a vessel, which may be taken as far as the principle involved is concerned to represent all her sections, and she to be inclined to the angle *x y z*, this will be as if the emerged solid *x y z* were carried over to *y b s*, and the power requisite to effect it will be great as the volume of these solids is great in proportion to the whole volume of the ship. If we suppose the ship's immersed depth to be only from *y* to *p*, then the volume of these solids will be greater in proportion to the volume of the ship than if her depth be increased to *w*; that is, suppose it possible while the vessel is inclined, that an increased volume were given between the line *x p s* and *x w s*; the volume of the solids *x y z* and *y b s* not being increased, the effect would be to float the keel up, and diminish the stability. This is what takes place when a vessel is made deeper in proportion to her breadth, yet, strange to say, the smaller vessels are those which are chosen to be made deeper, and so their proportionate stabilities are further reduced, though already small from their limited size, and less also, because they have received a less proportion of breadth to length; thus:—

	Mean draught.		Half-breadth.		Difference	
	feet. in.		feet. in.		feet.	in.
Marlborough .	25 0	to	30 6	=	5	0
Renown	24 0	to	27 6	=	3	6
Racoon	18 5	to	20 0	=	1	7

Now, if the smaller ships have sufficient breadth of beam for stability and for a good battery, then

* This will account for the great number of ships of the line which we possess, and which it is proposed should be allowed to rot.

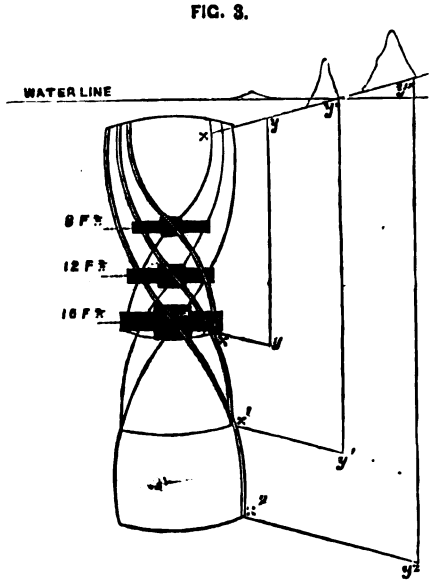
* By stability, here, I mean the power to resist inclination from the pressure of the sails, a quality which conduces under certain circumstances to fast sailing.

Digitized by Google

the larger ships must have too much; that they have will further appear from other considerations, for it cannot be said that the Renown, because of having a deck more than the Racoon, requires fifteen feet more breadth. Again, in order to obtain satisfactory results with a screw, that is, speed economically, it is necessary that the area of the screw shall bear a certain relation to the area of the greatest section, and that the screw shall be sufficiently immersed to obtain sufficient resistance to its thrust. From the following diagram it will be clear that the greater the diameter of the screw, the greater is the distance it should be immersed to obtain proportionate effect.

Suppose Fig. 3 to represent the forces given off by screws supposed proportionate to their di-

FIG. 3.



ameter—for it would be impossible to apply a large power to a screw of small diameter—then the lines $x\,y$, $x^1\,y^1$, and $x^2\,y^2$ may be taken to represent the direction and force of the thrust from each of 8, 12, and 16-foot screws respectively; from this it is clear that, if the larger screws are not more immersed than the smaller in proportion to their size, that part of their thrust will be lost in throwing up water at y^1 and y^2, instead of propelling the ship; this view of the case is confirmed by experience. This points to another ground of objection to giving great proportionate breadth to depth.

The area of greatest midship section, representing the principal element in resistance, will be the same whether the breadth and depth are—

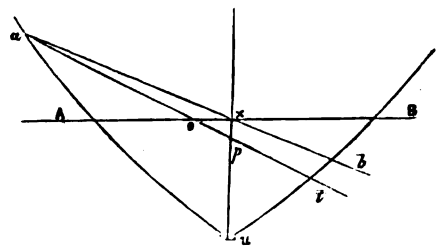
Breadth.		Depth.		
as 44	×	18·2	=	800·8
or 40	×	20·0	=	800

But in the one case the screw could be immersed two feet more, and its effective results proportionally increased. In illustration of this fact it may be stated, that, if the Diadem had been two feet deeper, though her displacement were also in that proportion increased, she would have been a faster, as she certainly would have been in every other respect a more efficient ship.

It has been stated that Sir William Symonds gave great beam to our ships, and that his successors did well to continue it; this is not true in fact, and, nominally, only true of the three-deckers, which, being larger, have equal breadth no doubt, but less in proportion to their length; still I assert that great beam is an unmixed evil.

The ships in question were uneasy, and it was assumed that, owing to the form of the solids immersed and emerged as they rolled, their centres of gravity rose and fell; that this was the sole cause of such motions; and that if their sides near the load water-line had been straight, or equally curved, this motion would not have taken place. This is a mistake, and one that has injuriously

FIG. 4.



affected nearly all our modern ships. The defect may arise from a different cause. 1st. I may explain the effect of the inequalities alluded to:—

Suppose $A\,B$, Fig. 4,* to represent the surface of the sea, and $x\,y\,u\,t\,r$ the outlines of a section of a vessel floating upright; for convenience of illustration, suppose the sea line moved on this section from $A\,B$ to $a\,b$; this supposes the vessel to have moved round z as the centre of her longitudinal axis, which cannot be, as the solids, emerged and immersed, must eventually, though not instantly, become equal, which is contrary to the supposition; consequently, the ship must rotate round some point, suppose o, at the inter section of the two planes that form two equal solids of emersion and immersion, in which case z and the centre of gravity equally will have been raised a perpendicular height equal to $z\,p$. In proportion as ships have this form near the load water-line—and all have it more or less at their extremities—will their centres of gravity be subject to a similar motion—the less, however, the better.

But a similar motion may arise from a form, the sides of which are "either perpendicular or equally curved" immediately above and below the load water-line.

The bottom of a ship is subject when afloat to an infinite number of pressures which act at points perpendicular to the surface with which they are in contact, and sustain her by their joint action; and, though there is ordinarily easy play amongst the particles through which these pressures proceed, yet, when motion round a longitudinal axis is communicated rapidly to such a body, the water resists proportionally, as though it were rigid, and the effect is somewhat similar to that which takes place when a body is rolled upon a rigid plane surface; this will take place whatever may be the force which communicates the motion, so that it be rapid in its action. If the force be applied at one side the body will rotate round some point on the other side of the centre of gravity from that on which the force is acting, and more distant as the form of the body is less circular, and less deep than wide. Suppose the inclining forces to be waves, which are the forces we have in most cases, these to be of equal dimensions, and to arrive at the side of each of figs. 5 and 6. Suppose y and y^1 to be the position of their centres of gravity; from a bare inspection of fig. 6 it will be evident that the common idea that when a vessel inclines she revolves round her centre of gravity, cannot possibly hold, even approximately, in vessels of

* This figure is exaggerated for better illustrating the point in view.

such a form; for if, on the wave arriving at the side of fig. 6, we suppose her to revolve round y^2, we must suppose a rapid and deeper immersion of one side of her bottom, from s^1 to t^1 against the pressures already on it, when she would assume the position represented by the dotted lines, which is obviously impossible. What takes place is, that the buoyancy added lifts the vessel high in proportion to its amount and the length of lever through which it acts, as compared with the resistance on the opposite side offered to greater immersion—the position the vessel would assume would be rather that of II, II than the dotted figure III, III.

It is equally obvious that the wider the vessel and the less the depth in proportion, the greater will be the amount of buoyancy added during the

FIG. 5.

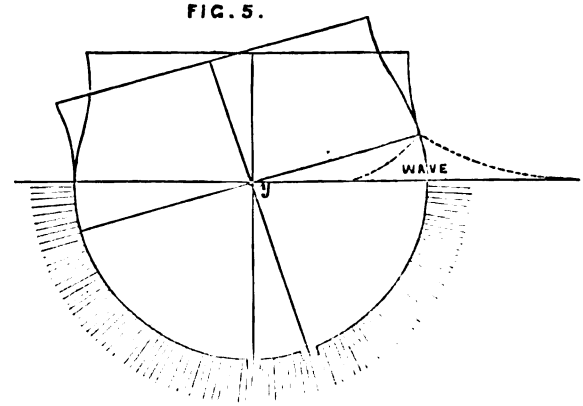


FIG. 6.

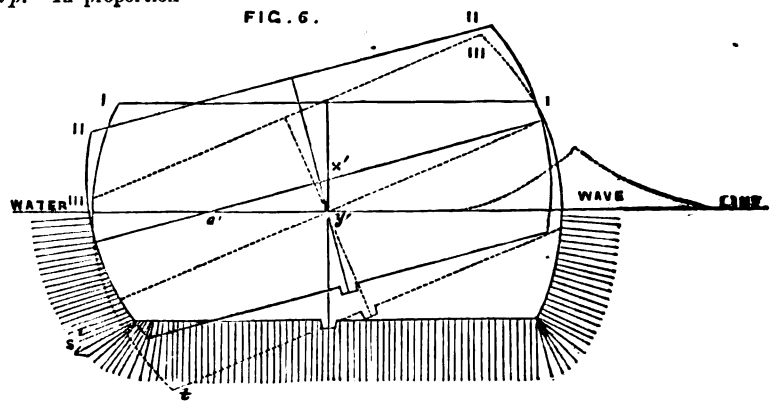

passage of a wave across the centre line of the vessel, the greater the lever to lift her and the higher will her centre of gravity be raised; the vessel will in reality rotate round some point, say o, and her centre of gravity will rise from y to x; when the wave passes the middle line of the vessel an opposite action will be set up, equally great in proportion to the breadth, but still greater and more rapid from the acceleration caused by the fall of the centre of gravity from the greater height, which will occasion the centre of gravity to rise proportionally higher on the succeeding roll. These motions will be violent, and something like that of a wheel going over a stone.

In vessels of the form of fig. 5 there is little of this motion, arising from the fact that the points of pressure are all equidistant from the centre, in consequence of which there never arises a sudden demand for a deeper immersion of any part than that which ordinarily obtains.

The motions alluded to above will take place irrespective of the position of the centre of gravity in the vertical plane; though its position might aggravate the evils described, no arrangement of weights could mitigate the evils of such bad forms as that of fig. 6.

(To be concluded in our next.)

"A letter from Rome states," says the *Builder*, "that the Pope has administered absolution to King Bomba by the electric wire. This is not only a new telegraphic process, but a new process of salvation, by electricity."

SIR WILLIAM ARMSTRONG ON HIS GUN AND PROJECTILES.

In addition to the remarks quoted in our "Gossip" of last week Sir William Armstrong spoke as follows in his speech at Newcastle:—"The percussion arrangement is such that the shell, while in the hands of a friend, is so safe and quiescent that it may be thrown off the top of a house without exploding, but when among enemies it is so sensitive and so mischievous that the slightest touch will cause it to explode. The reason of this is, that the shock which the projectile sustains in the act of firing puts the percussion arrangement from half to full cock, and it then becomes so delicate that a shell has been exploded at Shoeburyness by being fired against a bag of shavings. Moreover, the fuse may be so arranged that the shell explodes at the instant of leaving the muzzle. In that case the pieces spread out like a fan, and act as grape shot. I could give hundreds of examples of the effect produced by those shells; but I will confine myself to a single instance, which I select merely because it took place before the Duke of Cambridge, and many other officers of distinction. Two targets nine feet square were placed at a distance of 1,500 yards from the gun, and seven shells fired at them; the effect of these seven shells was that the two targets were struck in 596 places, and with so much force, that although one of the targets was three inches thick it was riddled through and through with the fragments. Similar effects were produced at much longer distances, extending in some cases to 3,000 yards. I leave you to conceive what would be the effect of these projectiles in making an enemy keep his distance. For breaching purposes, or for blowing up buildings, or for ripping a hole in the side of a ship, a shell of a different construction is used. The object in that case is to introduce the largest possible charge of powder. To go back to the commencement of my experiments, and give you a brief history of my proceedings. They commenced upwards of four years ago; my first gun having been commenced in December, 1854, and finished early the following spring. Although this gun was, in fact, constructed upon precisely the same principle as those now making, it did not, on trial, afford satisfactory results. Schemers, whose inventions only figure on paper, have little idea of the difficulties experienced by those who carry their inventions into actual practice. I met with my full share of difficulties, for it took me three years of continual application to surmount them. In the height of summer my experiments were conducted at the sea-shore, between the hours of three and six o'clock in the morning. People after that time began to move about, and were apt to get in the way. I dare say I owe an apology to many of my neighbours for disturbing them at very untimely hours. At other seasons I went to the moors of my friend Mr. Beaumont, at Allenheads, and there I had a hut constructed on a ridge 2,000 feet above the level of the sea, with a large valley beneath, with nothing more almost than the grouse or sheep running the risk of being shot. I used to awaken the denizens of the heath by the firing of my shells at my distant targets in the middle of the night. At the end of the three years all began to go right. I then succeeded in making several guns upon my own responsibility, and incurred very considerable expenses; but all those expenses were reimbursed by the Government. I take this opportunity of mentioning this because some misapprehension prevails upon the subject. General Peel, Lord Panmure, the Duke of Newcastle, the three Ministers who held office during my operations, as well as all the permanent authorities of the War Office, uniformly accorded to me all the support I could desire. At the beginning of last year a committee was appointed to investigate the whole subject of rifle cannon, and for a period of five months this committee gave nearly their whole time to the guns, projectiles, and fuses which I submitted to them, and finally gave a unanimous verdict in favour of the whole system. With regard to the precision and range attained with these guns, I have but little to add to what General Peel has already stated upon the subject. Since those statements were made, improved results have been obtained by means which it is not necessary, and would not be proper to explain. At a distance of 600 yards an object not larger than the muzzle of an enemy's gun or the crown of a man's hat can be hit almost at every shot. At 3,000 yards a target 9 feet square, which at that distance appears a mere speck, has, on a calm day, been struck five times out of ten. A ship affords a target large enough to be hit at a very much longer distance, and shells may be thrown into fortresses from distances exceeding five miles. To do full justice to this weapon when used at long distances, it would be necessary that gunners should undergo a much more refined and scientific course of instruction than they are now accustomed to. I hope and believe both the naval and military departments will take measures to afford the necessary instruction both to officers and men. It is an interesting subject to consider what will be the general effect of the introduction of these weapons upon the various operations of war. And first, as regards ships being opposed to ships on the open sea, it appears to me they would simply destroy each other, if made of timber. The time has gone by for putting men in armour, but I suspect it is only approaching for putting ships in armour. Fortunately no nation in the world can play at that game so well as we can, for our resources, both in the production of iron and in its application to all manner of purposes are unbounded. As regards a ship opposed to a battery, the advantage will unquestionably be in favour of the battery. It has a steady platform of guns, and it is composed of less vulnerable material. In cases of invasion, the possession of artillery of this description is all-important to the defenders. I believe it would be quite impossible to effect a landing if opposed by batteries of these guns, or if a landing were effected, the attacking forces would have to be most awfully cut up.

ON TIMBER FOR SHIP-BUILDING.

(Continued from p. 319.)

GUIANA is another country from which we may reasonably anticipate a very much larger supply of timber than we now obtain. Already it furnishes two out of the eight first-class woods recognized by Lloyd's, viz., the mora and the greenheart; but there are in the country several other most valuable timber trees, such as the kakaralli, the locust, the cabacalli, the bullet tree, the sewari, the carana or red cedar, the kuraki, the determa, the cuamara or tonka, &c., &c. If well-directed efforts were, however, made to increase the supply of the greenheart and the mora alone, immense quantities of both might be obtained. Greenheart is very abundant within 100 miles of the coast, and can be had almost to any extent, but the mora is even still more abundant. "This most majestic of all the forest trees of Guiana towers above every other, often attaining a height of from 100 to 150 feet, the lowest branches being 60 ft. from the ground. The wood is extremely tough, close, and cross-grained, so that it is difficult to split, which renders it peculiarly adapted for ship-building. The trunk makes admirable keels, timbers, and beams, and the branches, having a natural crookedness of growth, are unsurpassed as knees. Were men-of-war ceiled with this wood, little mischief would be occasioned by splinters during action. In most respects it is superior to oak, particularly in its exemption from dry-rot. It is abundant along the rivers of the coast region, and extends as far south as lat. 3° N. It grows luxuriantly on sandy reefs, and on tracts of barren clay, known as "mora clay," a soil so sterile as not to admit of profitable culture. Sir R. Schomburgh, referring to this tree, says, "In all my former travels in Guiana I have nowhere seen trees of this description so gigantic as on the land adjoining the Berima, at its upper course. On this upper part of the river the mora is so abundant, and grows to such a size, that the whole British Navy might be reconstructed, merely from the trees which line its banks; a circumstance well worthy of consideration, for the river being navigable for vessels of 12 feet draught, those intended for the transport of the timber might load at the very spot where the trees are cut down." There can be little doubt, then, that these two famous woods can be obtained in quantities limited only by the supply of labour that can be applied to this particular pursuit. Unfortunately, labour is both scarce and expensive in Demarara, presenting an obstacle more difficult to surmount than may be imagined. I am not quite sure that it would not be a good plan to induce the immigration of 100 Honduras wood-cutters, and establish them on some choice timber locality, so that whilst they are pursuing their accustomed labour, they might gradually draw around them those wild and adventurous spirits who would prefer the excitement of such a life to the dull monotony of a sugar estate.

I do not believe that any great increase in the exports of timber can be anticipated from India Proper; but I think that the exertions of Government might induce a very large supply from Assam. I have in my possession various lists by Dr. Wallick, Mr. Masters, Major Hannay, and Mr. Martin, of the timber woods of Assam, amongst which we find a light and valuable kind of teak, the Saul (*Shorea robusta*), the Dalbergia Sissoo, the oak, and numerous others most important and valuable. Assam has the most complete water-carriage (the Calcutta steamer even going up to Gowhatti), and a population whose habits are well suited to such an employment as woodcutting; so that if proper measures were adopted, an immense quantity of first quality timber might be annually sent down from this rich country. The Tenassarim provinces are perhaps more abounding in fine valuable timber for shipbuilding than any other country in the East.

A quantity of teak has, for many years, been exported from Moulmain and other ports along the coast; but the field which this healthy and most pleasant country still presents is so inexhaustible, that I consider it to stand unrivalled as a timber-producing country. Hitherto teak alone has been exported, but there are others which are considered quite equal, and even superior to it. The following list of some of the best timber woods will serve to give an idea of the capabilities of these neglected provinces:—

Anan.—One of the hardest and most compact woods known.

Ahnaun.—Strong and very durable; used in ship-building.

Keoun-lac (*Rottlera*).—Excellent for rudders.

Kat-wat-nu (*Cedrela*).—Large timber, 40 to 70 feet long; used for shipbuilding.

Ka-nyeng-kyaung-khyay.—For shipbuilding; contains an aromatic oil, and is not attacked by insects.

Kyep-yo.—Similar to teak.

Kud-doot-alain.—A large tree; used in ship-building.

Kunnazoo.—Very large tree; very hard and durable timber.

May-maka.—Used in shipbuilding.

May-rang.—Said to be very durable.

May-tobek.—Used for the bottoms of ships; considered preferable to teak.

Mayam.—An indestructible, strong, heavy, dark red wood.

Podauk.—A beautiful, compact, and hard wood, sometimes called "Rosewood."

Pengadoh.—Strong and durable.

Pien-mahne.—Yields very strong knee timber.

Pyan-ga-dean.—Hard, dense, and durable; called "iron wood."

Soondra.—A very tough, elastic wood; said to be the strongest of all the Indian woods.

Thab-ban.—Fine solid timber, sometimes 70 feet long; used for boats.

Than-kya.—A species of wood similar to saul.

Tha-nat.—A kind of grey teak.

Tha-nat.—More resembling saul.

Than-that.—A capital wood, like saul.

Theet-ya-han.—A species of teak—close grained.

Theng-gan (*Hopea Odorato*).—An enormous tree, of the saul tribe; yields a strong, compact, and excellent timber, considered superior to teak—also a quantity of good dammer, or resin. Insects never attack this wood, nor is it liable to rot.

Tirbbac (*Quercus Amherstiana*).—An oak; a large tree, used in boat-building.

Thounsanga.—A large tree, used in boat-building.

Thingan-kyaup.—Close grained, strong, heavy wood; used in ship-building.

Thubbae (*Mimusops*).—Used in ship-building.

Thuhbor (*Uvaria*).—A large tree, used in boat-building.

Toung-byeng.—A kind of red saul.

Thym-bro.—Good, strong, durable wood; used in boat-building.

In this list I have mentioned but a few of the truly valuable timber woods abounding in the provinces of Amherst, Tavoy, and Mergui; and it must be understood that I have not included the well-known teak, which has so long been the grand staple product of the country, although enormous quantities of this celebrated wood yet remain.

Digitized by Google

Under the old system of the East India Company, the "rules and regulations" for teak cutting were stringent enough, but were rarely acted up to. Licenses were granted only on the conditions, first, that the selected trees were to be barked all round, so as to kill them, two years previous to their being felled, in order that only seasoned wood should be sent to market; and secondly, that for every tree cut down, another young teak tree should be planted carefully out, for the benefit of the country hereafter. I do not know whether these "rules" still continue in force. It will be seen that timber cutting, therefore, has long formed one of the most important occupations of the people residing in Tenassarim; but we may go very much further than even the knowledge of this fact would lead us, inasmuch as we may view the Muggs, the Taliens, and the Burmese, as being all more or less expert in the use of the axe and the adze, as well as in the knowledge of the various qualities and uses of their forest trees. There would be no difficulty, then, in organizing large bodies of these men, as "timber gangs," their wages being 10s. a-month; but, as these provinces are scantily populated, any additional number of men might be procured (if necessary) either from among the Hill Coles, or from the adjoining territories of Siam, both of whom I have myself largely employed, and can vouch for their being excellent woodsmen. Under any circumstances, these labourers would not cost more than 12s. per month. On the score of climate, it may be said that there is not a more healthy tropical climate in the world, both for natives and for Europeans. In fact, the late Dr. Helfer, Mr. Riley, and others, long resident in the country, have expressed themselves most enthusiastically in respect of it. The three provinces are thoroughly intersected and opened up by water communication for the woodman, by the Great and Little Tenassarim, the Tavoy, the Ye, the Attaran, the Gyne, the Houndran, the Lenya, the Pak Chan, and numerous other rivers and streams. Along the banks of these rivers vast quantities of timber exist, which with the greatest facility may be floated down to the sea. The numerous beautiful islands forming the Merguian Archipelago also present advantages of the highest character, and contain harbours scarcely surpassed by any in the world.

Malacca (under which head I comprise our three settlements in the Straits of Malacca, viz., Pinang, Malacca, and Singapore) abounds in valuable timber woods, which are almost wholly unknown in Europe.

My friend Mr. J. W. Westerhout, the Assistant Resident of Malacca (where he was born, and has always lived), has furnished the following list of its principal woods:—

Tampanees, Blean, Murbouw, Tamboosu, Tampang, Kalat Merah, Medang Katanahan, Natoo, Galam Tekoos, Madang Boagah, Rangas, Madang Konjcet, Madang Lawang, Laniooso, Madang Paranas, Madang Langadee, Rassaak, Madang Kawan, Madang Samenjaak, Saraya, Marantee, Lida Karabouw, Pisang Pisang, Mangaranan, Pataleng, Madang Taloor, Dalle Dallee, Baloon Ejook, Salomar, Bintangoor, Bonoot, Kampaas, Madang Kaladee, Jabootong, Giham, Paning Paning, Madang Tandook, Sagah, Panagah, Kalat Potee, Pannah, Marsanah Kalat Lapies, Kledang, Tarantang, Pinang Bahie, Chengal, Brombong, Tolang Daleeng, Cheehaar, Menkadoo Ootan, Golam Zekoos, Gombang, Kalaat Merah, and Maraboun Lahoot.

My own experience of these woods (during my residence in the Straits) was principally confined to the following, which I am able to describe and characterise:—

Murbouw.—Very strong, hard, and heavy: used in shipping; not attacked by insects; will last 100 years.

Bintangoor.—Valuable wood for ship-building, especially for planks, masts, spars, &c. It grows in great abundance, especially near Singapore, and is largely exported to Mauritius, California, &c.

Damerlaut.—Hard, tough, and very valuable.

Giham.—A pale yellow wood, close-grained, hard, elastic, very durable, and generally used in boat-building.

Tampanee.—Used for house-building; hard, and exceedingly durable.

Tamboosu.—House beams; considered very durable.

Galam Tikoos.—Hard, tough, elastic; used in boats.

Marantee.—Very large; light resinous wood, much used for planking, and in building boats.

The Straits settlements of Malacca although near the equator, enjoy a healthful and salubrious climate, and have an abundant population of Malays and Chinese, whose wages average three to four dollars a month, without food. The Malays are first-rate woodsmen and boatmen, admirably adapted for such work as procuring timber; whilst Chinamen are most industrious labourers, and extremely enterprising contractors for all kinds of work. I consider this locality, therefore, as affording a promise of a very large supply of timber immediately measures are taken to commence the undertaking, for the natives themselves will not be backward in entering into the spirit of the enterprise.

[We are compelled to defer the publication of the conclusion of this paper until next week.]

GUNPOWDER EXPLOSIONS AT HOUNSLOW.

THE verdict of the jury in the Hounslow Gunpowder Explosion is as follows:—"We find that the deceased Thomas Albone was killed by injuries inflicted in and upon his body by the explosion of a certain large quantity of gunpowder at the mills belonging to Messrs. Curtis and Harvey, but by what means the explosion took place there was not sufficient evidence to prove. In returning this verdict the jury feel it to be an imperative duty to express their opinion that the works of Messrs. Curtis and Harvey, where the explosion took place, have been conducted in an exceedingly loose and dangerous manner, and that the safety of the workmen engaged in such establishments, and of the public generally, requires the immediate enactment of a law for subjecting all gunpowder manufacturers to the stringent supervision of Government inspection and control, with a view to the invariable adoption of the precautions and recommendations similar to those contained in Dr. Thompson's report. The jury think it right to notice that of late years the works in question have been greatly, and as they believe unlawfully, increased, and that gunpowder has been kept in such vast quantities as to be attended with danger to workpeople employed therein, as well as to the inhabitants of the surrounding neighbourhood." The verdict of the jury was scarcely recorded when another explosion occurred at the same establishment, which it is much to be feared, will be attended with fatal consequences. On Tuesday night, at a quarter past 11 o'clock, the inhabitants of Twickenham and the adjacent neighbourhood were greatly alarmed by a succession of explosions that shook the houses and rattled the windows for several seconds. Many persons left their homes, and others who had retired to rest got up to ascertain the cause of alarm. Upon inquiry it was found that the department of the works known as the "incorporating mills," had blown up. These mills, four in number, are situate near the engine-house, in one line of building, through which a shaft runs that turns four pairs of immense iron-edge runners, used for grinding the various articles together of which the powder is composed—viz., saltpetre, charcoal, sulphur. During this process, the composition is kept continually damp by the application of water, and in this stage is called "green charges." The whole of these mills are destroyed, and one poor fellow named Allen has received such injuries that it is scarcely possible he can recover. During the inquiry before the coroner, on Tuesday, it was stated by Mr. Ashby, the manager of the works, that a large accumulation of powder in the various corning and glazing houses was considered more desirable than the risk of transferring it frequently through the vicinity of the mills. There is no doubt that this accident, occurring so immediately after the presentment of the jury, will tend to a new arrangement of the various departments, that shall lead to greater security to the persons engaged, and diminish the excitement and alarm that now exist in the neighbourhood.

Law Cases.

COURT OF QUEEN'S BENCH, Westminster, April 16.—*Sitting in Banco, before Lord Campbell and Justices Erle, Crompton, and Hill.)*

NORTON v. NICHOLLS.

THIS was an action brought to recover damages for the infringement of the plaintiff's registered design for a mantilla shawl. The Court had granted a rule for a new trial, or to enter the verdict for the defendant, and, after argument, had taken time to consider.

Lord Campbell now delivered the judgment of the Court, in favour of the defendant. On the part of the plaintiff five points were made, in respect of each of which it was contended the design of the plaintiff's shawl was new. The design was registered under the 5th and 6th of Victoria, cap. 100, and it was contended that if the defendant had imitated the design in any one particular, the plaintiff was entitled to recover. The shawl was reversible, and had two sides, was scalloped, had a particular border, a particular configuration of the corner, and a newly invented fringe. The great merit of the shawl was, that it could be made into eight several shawls, all seeming to be different. The evidence showed that all the five points relied upon were in public use before the registration of the plaintiff's design; but, it was contended, that the combination of all the five points in the plaintiff's shawl was new. The defendant's shawl was the same as the plaintiff's, only the colour was different. Thus the question arose, whether in respect of such an imitation the action could be maintained? The Court were of opinion that it was not. The Court did not deny that a combination might be a "design" within the meaning of the statute, but this was not so. The registration also was defective, consisting merely in leaving in the registry an entire shawl of the plaintiff's manufacture. That gave no notice of the nature of the plaintiff's claim. Nor had sufficient notice been given to the defendant of the plaintiff's exclusive right.—Rule accordingly.

THE VICE CHANCELLOR'S COURT.

TUCK v. SILVER.

Mr. Rolt and Mr. Fooks moved for an injunction on behalf of the plaintiff to restrain an infringement by the defendants of the plaintiff's patent in respect of india-rubber packing for pistons, piston-rods, and valves. Letters patent were obtained by the plaintiff on the 25th of August, 1854, and, in the specification, the invention of "improvements in packing for pistons, piston rods, valves, and other uses" was described as intended to combine a flexible material of canvas, coated or saturated with a solution of india-rubber, or other suitable composition, with an elastic material, so as to cause the former to be constantly kept in contact with the rubbing or tearing surface by the elasticity of the latter, this object being accomplished by constructing the packing with a block or core of india-rubber, or other elastic material, surrounded by folds of flexible material. The packing manufactured in accordance with the patent had acquired considerable reputation, and was known as "Tuck's Patent Elastic Core Packing." The defendants carried on business as outfitters and general merchants at Bishopsgate-street-within, and were also proprietors of a factory at Woolwich, known as "Silvertown Works." In August, 1856, the plaintiff, having discovered that the defendants were infringing his patent, wrote to them on the subject. On the 28th of August, 1856, the defendants replied that they were not aware of the existence of the patent until they had received the plaintiff's letter, and that they had discontinued the manufacture and sale of core packing, and would on no account resume them. The plaintiff had recently discovered that the defendants were selling elastic core packing similar to that manufactured by him under his patent, at exactly half the price, under the name of "Silvertown Packing." To restrain this alleged infringement of his patent the plaintiff had filed his bill, and now moved for an injunction.

Mr. W. M. James and Mr. Baggallay, for the defendants, contended that there had been no infringement: that the specification of the patent was vague, and did not state the employment of vulcanized india-rubber, which was alone available for such purposes, and that the patent itself was of doubtful validity, and, at all events, ought to be legally established before the plaintiff could obtain an injunction in this court.

The Vice-Chancellor said, that upon the two grounds of long and uninterrupted enjoyment under the patent, and of the special circumstances of conduct by the defendants, the plaintiff was entitled to the interlocutory injunction. The enjoyment had been for five years without interruption and with acquiescence. But the conduct of the defendants was alone sufficient to induce the Court to grant an injunction. After the assurance by the defendants in August, 1856, that they would on no account resume the manufacture or sale of "core packing," the plaintiff had no reason to suppose that he would be undersold behind his back, nor that the defendants were going to set up an adverse right and dispute his patent. But for the assurance given by them, the plaintiff would have tried his right more than two years ago, and he had been grievously wronged by the representation then made to him. This was alone sufficient ground for granting the interlocutory injunction. His Honour, after adverting to the arguments as to the patent being void for want of novelty, said that these were questions which would be for a jury to consider. There were material questions to be tried, and the plaintiff had established quite a sufficient *primâ facie* case to entitle him to an injunction until the hearing. With respect to putting him upon an undertaking, although the practice was modern, yet it was convenient and consonant with justice, more especially after the Act of last year, which enabled the Court to assess damages, and thus to complete justice between the parties. There would be an injunction until the hearing, the plaintiff undertaking to bring an action, and to abide by any order as to damages the Court might make at the hearing.

On Monday last Mr. John Laird launched from his shipbuilding yard at Birkenhead an iron steamer for the Russian Government, the first of three boats which he is building for river service. The second boat will be launched in about a fortnight, and the third immediately afterwards. These boats are said to be capable of being turned into gunboats at pleasure.

On Saturday last a large anvil block was cast at the foundry of Messrs. Morrison and Co., Ouseburn, Newcastle-on-Tyne. The block is for an immense hammer to be used at the making of Sir William Armstrong's guns at the Elswick Engine Works near that town. When finished it will weigh upwards of 21½ tons. It was cast in one run, and the quantity of metal melted for it was 23 tons. The size of the base of the block is 6 ft. 6 ins. by 9 ft., and its thickness 9¾ inches, and the size of the body part 3 feet 10 inches by 3 feet 9 inches. In consequence of the great heat still in the casting it will have to lie a week before it will be possible to raise it.

NOTICES.

The letter of P. M. stands over until next week.

The MECHANICS' MAGAZINE will be sent free by post to all subscribers of £1 1s. 8d., annually, *payable in advance*. Post Office Orders to be made payable to R. A. Brooman, at the Post Office, Fleet Street, London, E.C.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 5d. per line for any number of insertions less than 13; for 13 insertions, 4d. per line; and for 52 insertions, 3d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

Special Arrangements for larger or Serial Advertisements. To ensure insertion, Advertisements must reach the Office by 5 o'clock on Thursday evening each week. None can be received after that time for the ensuing number.

THE demand for Mr. E. J. REED'S paper—

ON THE MODIFICATIONS WHICH THE SHIPS OF THE ROYAL NAVY HAVE UNDERGONE DURING THE PRESENT CENTURY, IN RESPECT OF DIMENSIONS, FORM, MEANS OF PROPULSION, AND POWER OF ATTACK AND DEFENCE,"

has been so great that the Journal of the Society of Arts, the MECHANICS' MAGAZINE, and all other Scientific Journals in which it appeared in December last, are now out of print. The demand still continuing, it has been deemed desirable to reprint it in a separate form. An 8vo. edition of it, in large type, and on fine paper, has, therefore, been prepared, and may now be had at the Office of this Magazine, price 1s.

Our Weekly Gossip.

IN confirmation of the views expressed in our leading article on ship-building, we may state what we have just learned, viz., that the Admiralty are about to send an additional purveying officer out to Sardinia to assist in providing still larger quantities of Italian oak, for the frames of our ships of war, than are at present obtained. Even now, when the timber is used almost as soon as it is cut, without any time being allowed for the seasoning of it, the supply falls considerably short of the demand.

We have received, from Mr. Leonard Wray, a copy of a long letter addressed by him to the *Journal of the Society of Arts*, with a request that we would publish it at length. This we are reluctantly compelled to decline doing, as the letter would occupy too much of our space. An abridgment of it will perhaps answer the author's purpose. He writes in reply to the observations made by Mr. E. J. Reed after the reading of his (Mr. Wray's) paper on "Timber for Shipbuilding," at the Society of Arts. Mr. Wray first questions if "liquid fires" will "ever be adopted by any civilized nation in naval engagements that may be fought in our time," and then proceeds to examine the merits and demerits of war-ships built wholly of iron. His remarks are made upon the assumption that the present object is to make such ships "shot and shell-proof;" and he contends that they cannot be made to withstand a concentrated fire of solid shot. "Mr. Reed said to the members of the society," continues Mr. Wray, "'those present might judge for themselves what would be the effect of half-a-dozen shell-proof frigates making their appearance among a fleet of our wooden ships,' and, with all respect to Mr. Reed, I will answer that inquiry, by declaring that those six redoubtable frigates would be boarded and carried at sword's point in 'less than no time,' unless, indeed, our tars have greatly degenerated." If this be deemed a bold and unsupported assertion on Mr. Wray's part, he takes the "opinions of the dashing Dundonald, the undaunted Napier, and ninty-eight other 'British hearts of oak,'" and see how many of them will contradict and how many will confirm that assertion. He also supports the view by other arguments. He further contends that "to plug up a shot-hole in an iron ship is no such easy matter, partly from the jagged and irregular nature of the hole or rent itself, and partly from the want of adhesion between the iron and the wood; whilst the additional safeguard of planking over the plugged holes could not possibly be effected. During the Chinese war in 1843-44, this was clearly shown in the case of the Queen and one or two other iron war steamers belonging to the Indian Navy." In conclusion, Mr. Wray says, "I did not lightly hazard the opinion which Mr. Reed has attempted to refute; on the contrary, it is the conviction I have arrived at after maturely studying the question in all its bearings; and I trust that our Government, and the public at large, will 'read, mark, and carefully digest' the remarks contained in this communication. I fully agree with Sir John Pakington that, as the French are building thick iron-plated ships of war, we also must have them, and if possible with every available improvement. I am much pleased that Mr. Reed has opened up this question for discussion, as it tends to elicit opinions and facts which may have much practical value." To all this Mr. Reed briefly replies in a letter to the Secretary of the Society of Arts as follows:—"Sir,—On reading Mr. Wray's letter on the above subject, I find that in the remarks which I made at the meeting of your Society on the 6th inst., I negligently substituted the words 'shot' for 'shell,' and 'shot-proof' for 'shell-proof.' I very much regret this error, as it has put Mr. Wray to the trouble of using arguments which would not otherwise have been called for. I would here repeat, what I said at your Society in December last, viz., that 'the attempt to build ships which shall be proof to solid shot—at least to wrought-iron solid shot—is an altogether illusory one.' I shall not presume to follow Mr. Wray in his discussion of the general qualities of iron-coated ships. I will merely say that very destructive shells *are* now used in naval warfare, and I know of nothing to prevent the adoption of others still more destructive; and further—with regard to French shell-proof ships—I think it unwise to trust to capturing them by boarders; and this opinion is shared, I know, by many experienced naval men."

In a recent number of the MECHANICS' MAGAZINE public attention was called to a newly-manufactured substance, the uses of which promise to be innumerable—vegetable parchment. The simplicity of the process by which it is produced is as remarkable as are the qualities it is found to possess. Vegetable parchment, as we said, is blotting paper dried, after being passed through a solution of sulphuric acid—nothing more. From the effect of this operation, the weak, porous, non-fibrous material becomes on drying, tough, hard on the surface, and, in a high degree, fibrous! Its whole character, in fact, is changed. It is different in all respects, save one, to what it was before immersion. That one respect is its specific gravity. A sheet of blotting paper and a sheet of the same size of vegetable parchment are of equal weight exactly. It would be imagined that the thirsty blotting paper must drink up and retain some of the acid. If it does so, by some strange paradox the fragile and perishable paper remains, nevertheless, as heavy as the strong and everlasting parchment. It has been found by practical experiment, that vegetable parchment gives a writing surface far preferable to that of either paper or animal parchment—which latter is indeed troublesome to all but the users of quill pens—and that it receives freely oils and varnishes. For power to resist rubbing it is inferior to the sheepskin, but to paper it is far superior,—even to paper of the toughest kind. It is needless under these circumstances to attempt to catalogue the purposes to which this valuable commercial adjunct, which costs in manufacture little more than paper, and far less than animal parchment, may be applied. Each reader will imagine many such purposes for himself.

We hail with satisfaction the successive numbers of Mr. Charles Dickens's *All the Year Round*. One of the most valuable features of *Household Words* under his management was the series of articles in which scientific topics were very pleasantly and profitably treated. This feature is renewed in the new periodical. The third number contains an article on steam ploughing, which, although not unexceptionable in our judgment, will help, nevertheless, in its own way, to diffuse valuable information on the subject. The only quality of *All the Year Round* which we regard with particularly disfavour is its obtrusive praise of "beer." We are perfectly sure that Mr. Dickens—whose sympathy for the poor and the suffering makes him beloved by all—would do well to abstain from lending such continuous countenance to the most unmanly and degrading habit of this nation.

Some papers on the subject of decimal coinage in Canada have been returned to an address of the House of Lords, and printed. These include certain Acts of the Canadian Legislature (1851 and 1857), for the introduction of the decimal system into Canada, and the 3rd and 4th reports of the Select Committee of the Canadian Assembly on Public Accounts, in the session of 1855. This Committee submitted two resolutions for the consideration of the Legislative Assembly, as follows:—"That after the 31st day of January, 1856, there shall be but one currency of accounts and payment, of which the dollar shall be the unit and standard of value; the public accounts shall be kept in dollars, cents, and mills; and the coinage shall be equal in intrinsic value to that of the United States. That the ton of 2,240 lbs., the cwt. of 112 lbs., the half-cwt. of 56 lbs., and the quarter-cwt. of 28 lbs., be reduced to a ton of 2,000 lbs., and its subdivisions." The result was the passing of the following Act, assented to on June 10, 1857: "Whereas it will greatly facilitate the keeping and audit of the public accounts of the province, that the same be kept in dollars and cents.; therefore Her Majesty, by and with the advice and consent of the Legislative Council and Assembly of Canada, enact as follows:—1. All accounts to be rendered to the Provincial Government, or to any public officer or department in his province, by any officer or functionary, or by any party receiving aid from the province, or otherwise accountable to the Government or Legislature thereof, shall be so rendered in dollars and cents; but any such accounts may have a second column containing sums in pounds, shillings, and pence, equivalent to the sums so stated in dollars and cents, if the accountant shall prefer to render his account in that form. 2. The preceding enactment shall take effect upon, from, and after the 31st day of December, 1857, and not before." There is an immense number of letters and papers on the subject of decimal coinage, which emanated from mathematicians and other eminent authorities in Canada.

Patents for Inventions.

PROVISIONAL PROTECTIONS.

Dated March 30, 1859.

790. W. Brown, of Bolton-le-Moors, Clog Manufacturer. Improvements in manufacturing clog soles and in the machinery employed therein.

Dated April 2, 1859.

834. T. Williams, of Aberdaron, Engineer, and J. H. Fuller, of Hatton-garden, Tool Manufacturer. Improvements in screw stocks and dies.

Dated April 4, 1859.

838. C. F. Kirkman, of Argyll-st., Gentleman. Improvements in the manufacture of cocoa nut fibre yarn and matting.

Dated April 5, 1859.

848. A. Shanks, Engineer, of Robert-st., Adelphi. Certain improvements in machinery for forging and stamping metals.

856. T. Scott, of Dundee, Gentleman. Improvements in preparing, treating, or manufacturing fibrous materials, and in the apparatus employed therein.

Dated April 9, 1859.

886. T. Spencer, of Euston-road, Chemist. Improvements in the economical treatment of refuse or waste matter containing sulphur.

Dated April 11, 1859.

898. B. Baugh, Manager, of Birmingham. Certain improved arrangements for working fly presses by steam, water, or other power.

900. W. Schofield, of Thomas-st., Blackfriars-road, Mineral Water Manufacturer. An improved effervescing lemonade.

Dated April 13, 1859.

926. R. Coleman, of Chelmsford, Agricultural Implement Manufacturer. Improvements in agricultural implements.

930. J. A. Coffey, of Providence-row, Finsbury, Engineer. Improvements in apparatus for heating liquids.

Dated April 14, 1859.

934. J. Gillett, of Upper Brailes, Warwick, Agricultural Implement Maker. An improved mill used for grinding, crushing, and reducing bones and other mineral and vegetable substances.

936. T. Bird, of Manchester, Engineer. Improvements in the application and use of a certain natural product or products in the manufacture of pickers for looms, drawing rollers for spinning machinery, cop tubes, and for steps and bushes generally where lubrication is required.

938. J. Beattie, of South Lambeth, Engineer. Improvements in the means of preventing locomotive engines and carriages in motion on railways leaving or running off the rails.

940. W. Barnes and S. Pickering, Spitalfields, and J. Roberts, of Limehouse. Improvements in retarding and stopping railway locomotives and trains.

942. W. Sinnock, of Brompton, Kent, Ropery Engineer. Improvements in submarine and subterranean electric telegraph cables, and in machinery for the manufacture thereof.

944. L. J. Higham, of New York, Gentleman. Improvements in billiard tables.

Dated April 15, 1859.

948. J. Chapman, of Wolverhampton, Ironmaster. An Improvement or improvements in the manufacture of angle iron.

950. R. Boot, of Hill-st., Surrey, Leather Dresser. Improvements in treating sheep or other pelts, so as to give them the appearance of rough calf.

Dated April 16, 1859.

952. H. Barrow, of Birmingham, Saddler. A new or improved fastening for fastening trunks, boxes, and articles of dress, and for such other purposes as the same is or may be applicable to.

954. J. Glasgow and S. Hand, of Manchester. An improved variable circular motion, applicable to slotting, shaping, and planing machines, or similar purposes.

956. W. Clark, of Chancery-lane. Improvements in apparatus for separating metals from their ores and other matters. A communication.

958. J. Hamilton, of Glasgow, Engineer. Improvements in apparatus for regulating prime movers driven by water.

Digitized by Google

960. H. Harrison, of Blackburn, Machine Makers. Certain improvements in looms for weaving.
962. H. H. Vivian, of Swansea, M.P. Improvements in smelting copper.
964. G. B. Cornish, of New York, Master Mariner. Improvements applicable to fog-horns.
966. J. Moule, of Hackney-road. A new compound liquid for illuminating purposes.

Dated April 18, 1859.

968. R. Warry, Armourer-Serjeant, of Chatham. Improvements in breech-loading ordnance and its projectiles.
970. G. Porter, of London, Gas-Fitter. Improvements in valves or cocks.
972. J. Seaman, of Linslade, Buckingham, Engineer. Improvements in agricultural implements for working or cultivating the soil.
974. J. C. Wilson, of Wood-st., City, Warehouseman. A reversible shawl cloak.
978. J. and H. S. Morton, of Sheffield, Grate Manufacturers. Improvements in hearth-plates or ash-pans.
980. G. Coller, of Harlow, Essex. An improved mowing machine.
982. W. Parsons, of Pontar-Tawe, near Swansea, Tin Plate Manufacturer. Improvements in preparing sheet iron and other metal sheets for japanners and other uses.

Dated April 19, 1859.

986. C. Batty, of Manchester, Collector. An improved means or apparatus for effecting instantaneous communication on railways between passengers and officials.
990. J. W. Matthews, of Poplar, Hat Manufacturer. An improvement in the manufacture of hats and other coverings for the head.

Dated April 20, 1859.

992. Q. Beck, of Belfast, Manufacturer. Improvements in stoves. A communication from J. Cherry.
994. J. M. and E. Johnson, of Castle-st., Holborn. Improvements in the production of ornamental surfaces suitable for advertisement tablets, plates for shop fronts, and for other uses.
996. H. Rawson, of Leicester. Improvements in machinery for combing wool and other fibres.

Dated April 21, 1859.

1000. E. Cottam, of Pimlico, Engineer. Improvements in apparatus employed for cutting or sawing metals and other substances.
1002. J. Napier, Gentleman, of Partick, near Glasgow. Improvements in producing figures or representations upon glass.
1004. J. Davies, of Tetbury, Machinist. A new or improved apparatus for ringing door bells, and a bolt to be used with the said apparatus, and for other purposes to which the said bolt is or may be applicable.
1006. R. A. Brooman, of 166 Fleet-st., London, Editor of the MECHANICS' MAGAZINE and Patent Agent. Improvements in knitting frames. A communication from Madame Hammerlin.
1008. E. Clark, of New York, Gentleman. Improvements in sewing machinery. A communication from I. M. Singer.
1010. T. S. Truss, of Darlington, Civil Engineer. Improvemen's in the construction of pipes, and in the mode of joining the same.

Dated April 23, 1859.

1014. C. Mansel, of Plymouth. A folding travelling case.
1016. J. Armstrong, of Sunderland, Timber Merchant. Improvements in drying and preserving timber.
1018. J. Angus, of Glasgow, Ironmonger. Improvements in saddles.
1020. P. L. M. Debain, of Paris, Gentleman. Improved means for transmitting motive power to ships, pumps, and other arrangements by which the displacement of fluids is effectuated.
1022. P. L. M. Debain, of Paris, Gentleman. Improvements in making heat subservient for producing motive power.
1024. R. A. Brooman, of 166 Fleet-st., London, Patent Agent. An improvement in the manufacture of woollen cloth. A communication from L. V. Lemaignen.
1026. W. Moxon, of Parliament-street, Westminster, Contractor, and J. J. Bennett, of Victoria Park, Civil Engineer. Improved apparatus for raising or lifting and lowering heavy bodies.

Dated April 25, 1859.

1028. W. Stevenson, of Johnstone, Renfrew, Manager. Improvements in spinning, doubling, and manufacturing cotton, and other fibrous materials.
1030. J. Higgin, of Manchester, Manufacturing Chemist. Improvements in treating madder, and plants of the same family, and preparations therefrom.
1032. J. Owen, Designer, and H. Duckworth, Manager, of Blackburn. Improvements in machinery or apparatus for leasing yarns.
1034. T. Buckham, of Gloucester, Civil Engineer. An improvement in railway switches.
1036. A. W. Gadesden, of Leman-st., Goodman's Fields. Improvements in producing solutions of sugar.
1038. W. E. Newton, of Chancery-lane. Improvements in sewing machines. A communication from R. H. and A. D. Morford.
1040. W. Warne, J. A. Fanshawe, J. A. Jaques, and T. Galpin, of Tottenham, India Rubber Manufacturers. Improved compounds applicable for packing the joints of steam or other pipes, which compounds are also applicable for packing or lining parts of machinery in general, or parts of ships, bridges, tanks, or railways.

Dated April 26, 1859.

1042. T. Holt, of Rochdale, Engineer, and J. Brown, of the same parish, Agent. Improvements in apparatus, or an improved apparatus, for heating water for the supply of steam-boilers, which improvements or apparatus are also applicable in some cases for the prevention of incrustation in steam-boilers.
1046. R. Main, of Birkenhead, Carriage Builder. Improvements in wheels for carriages.
1048. R. A. Brooman, of 166 Fleet-st., London, E.C., Patent Agent. Improvements in vulcanizing and colouring caoutchouc, and in the preparation of caoutchouc paints and colours. A communication from T. J. Laballe, of Paris.
1050. J. H. Johnson, of Lincoln's-inn-fields. Improvements in machinery or apparatus for combing wool and other fibrous substances. A communication from C. Whipple.

Dated April 27, 1859.

1052. J. M. Ciroux, of Brussels, Merchant. Improvements in lamp-glasses and shades, applicable to gas-burners, light-houses, and railway-signals.
1054. J. Hyde, of Hollingworth, near Mottram, Engineer, Certain improvements in steam-boilers.
1058. R. J. Laing, of Haggerstone, Engineer. Improvements in wet gas-meters.
1060. J. Holroyd, of Leeds, Cloth Finisher. Improvements in machinery used for finishing woollen and other cloths.
1062. Sir T. T. Grant, K.C.B., of Chester-terrace, Regent's-park. Improvements in ships' cooking apparatus.

Dated April 28, 1859.

1066. R. Jones, of New Kent-road. An improved safety lamp.
1068. N. Libotte, Mechanician, of Paris. A steam brake for mines, which may also be worked by hand.
1072. J. Wheat, of Hinckley, Leicester. Certain improvements in drilling-machines employed for agricultural purposes.
1074. A. Boyle, of Birmingham, Tool Maker. Improvements in the manufacture of certain parts of umbrellas and parasols.

Dated April 29, 1859.

1078. H. Bosshard, of Paris, Engineer. An improved mechanism for obtaining and imparting motive power.
1080. S. de Cazenave, of Regent-street. An improved lubricating compound.

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

1153. J. Luis, of Welbeck-street. A self-regulating horse machine. A communication from P. I. Garin. Dated May 9, 1859.
1161. G. G. Bussey, of New Oxford-st., Manufacturer. An improved contrivance for carrying cartridges, and to facilitate using them. Dated May 9, 1859.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(*From the London Gazette, May* 17, 1859.)

29. W. Renton, T. Renton, and W. Binns. Textile fabrics.
36. C. De Forest. Springs. A communication.
47. W. Renton, T. Renton, and W. Binns. Finishing fabrics.
48. J. Aspinall. Bolts, rivets, and spikes.
54. J. J. Florance. Spooling-wheels.
67. W. Clark. Phosphates of lime. A communication.
69. J. T. Forster. Bed berths.
70. W. E. Newton. Steam-engines. A communication.
72. R. D. Clegg. Signalling apparatus.
78. T. H. Toms. Textile fabrics.
79. E. Agneni. Pictures, landscapes, &c.
81. J. Biers, jun. Carriage break.
84. D. E. Hughes. Insulating wires.
85. B. J. Rubenstein. Dentistry.
87. C. W. Siemens. Supports for telegraph wires.
89. N. P. Burgh. Steam-engines.
90. S. Canning and H. Clifford. Paying out and recovering telegraph ropes.
97. T. Elwell. Governors.
98. W. McNaught. Steam-engines.
103. C. Beslay. Coating iron or steel.
108. H. Critchley. Pistons.
112. D. L. Banks. Suspension roadway.
118. T. Herbert. Warp lace.
129. W. H. E. McKnight. Boiler.
131. D. L. Banks. Suspension roadway.
139. P. A. S. Sicard. Steel.
142. E. Brooks. Locks.
167. J. H. Johnson. Lasts, &c. A communication.
182. H. Sagar and A. Schultz. Cotton fabrics.
183. T. Richardson. Manure.
201. D. Moseley. India-rubber thread.
217. A. Warner. Iron.
251. E. T. Hughes. Biscuits. A communication.
262. H. Watson. Paper.
265. J. Lane. Screws.
269. H. Grissell. Moving ships.
367. J. H. Johnson. Fire-arms. A communication.
432. A. V. Newton. Brushes. A communication.
757. J. H. Johnson. Fire-arms. A communication.
845. D. B. White. Pumps.
901. J. Anderson. Furnaces.
970. G. Porter. Valves or cocks.
996. H. Rawson. Combing fibres.
1003. J. Alison. Extirpating thistles, &c.
1016. J. Armstrong. Preserving timber.
1018. J. Angus. Saddles.
1040. W. Warne, J. A. Fanshawe, J. A. Jaques, and T. Galpin. Packing the joints of pipes, &c.
1042. T. Holt and J. Brown. Steam-boilers.
1058. R. J. Laing. Wet gas meters.
1074. A. Boyle. Umbrellas and parasols.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed May 12, 1859.

2547. J. Courage and F. Bennett.
2548. J. Taylor.
2551. L. Petre.
2552. I. Livermore.
2557. M. Pullan.
2558. J. A. Hopkinson.
2562. G. Davies.
2568. J. G. Bunting.
2569. J. Brennand.
2571. J. C. Boisneau.
2572. A. I. H. Parent.
2573. J. Samuel.
2575. C. J. C. Perry.
2587. J. Robertson.
2641. D. Evans.
2649. F. A. Theroulde.
2669. J. S Nibbs.
2702. G. B. Sander.
2723. D. Evans and G. Jones.
2736. R. H. Bow.
2752. J. Lewis.
2779. J. B. A. Monnier.
18. I. Wood.
83. R. and W. Hawthorn.
137. J. Montgomery.
205. W. E. Newton.
435. J. J. Russell.
437. J. Seguin.
568. W. Score.
577. C. R. Mead.
615. J. S. Russell.
630. A. V. Newton.
642. A. Tylor.
705. A. V. Newton.
729. Sir P. Fairbairn and R. Newton.

Sealed May 14, 1859.

2564. W. G. Armstrong.
2583. C. F. Vasserot.
2584. J. H. Tuck.
2586. E. Welch.
2589. E. Mellor.
2591. J. Brennand.
2592. R. A. Brooman.
2598. S. Riley.
2601. Sir C. T. Bright.
2603. H. Stott.
2608. E. T. Archer.
2612. W. S. Hayward.
2616. W. Hancock.
2618. H. H. Henson.
2619. W. Ramsear and J. G. Scott.
2620. E. A. Pontifex.
2621. H. Bailey.
2622. W. Clark.
2627. A. J. Thorman.
2654. W. Ralston.
2655. W. H. Dawes.
2730. A. E. C. Scheidel.
2764. G. E. Noone.
2773. L. W. Fletcher.
2944. E. Fellows.

PATENTS ON WHICH THE THIRD YEAR'S STAMP DUTY HAS BEEN PAID.

928. U. Scott.
1105. R. A. Brooman.
1124. H. Tucker.
1138. U. Scott.
1150. J. Leck and A. Miller.
1152. H. Greaves.
1162. W. Henderson.
1175. R. Knight.
1185. J., T., and G. Wilkes.
1201. A. H. Dufresne.
1206. A. Allan and T. Hunt.
1246. R. A. Whytlaw and A. Mitchell, jun.
1254. W. Hulse.
1255. C. Cowper.
1270. L. D. Owen.

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

STEAM ENGINES, &c., 2255.

BOILERS AND THEIR FURNACES. *None.*

ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 2275, 2284.

SHIPS AND BOATS, including their fittings, 2274, 2276, 2290.

CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 2261, 2279.

FOOD AND BEVERAGES, including apparatus for preparing food for men and animals. *None.*

FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 2250, 2252, 2256, 2260, 2285, 2286.

BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c. *None.*

LIGHTING, HEATING, AND VENTILATING, 2257, 2265.

FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 2282, 2287.

METALS, including apparatus for their manufacture, 2243, 2289.

CHEMISTRY AND PHOTOGRAPHY, 2247, 2262.

ELECTRICAL APPARATUS, 2245, 2251, 2270.

WAR FARE, 2243, 2246, 2269.

LETTER PRESS PRINTING &c. *None.*

Digitized by Google

MISCELLANEOUS, 2244, 2248, 2249, 2253, 2254, 2263, 2264, 2266, 2267, 2268, 2271, 2272, 2273, 2277, 2278, 2280, 2281, 2283, 2288, 2291.

2243. C. W LANCASTER. *A metal or metallic alloy especially adapted to the manufacture of fire-arms and ordnance.* Dated Oct. 8, 1858.

This is composed of copper and aluminium in or about the proportions of 90 parts of copper to 10 parts of aluminum. *Patent completed.*

2244. A. FELTON. *Improvements in instruments used for inserting and fixing metal eyelets.* Dated October 8, 1858.

This consists in the application of knives or cutting edges to the punch or presser of spring nipper eyelet fasteners, so that, when closing the nipper on the eyelet, the knives or cutting edges sever the lip of the eyelet at first when it is being turned over, causing it to separate at several places, whereby the turning over is more uniformly effected, and the eyelet better secured to the leather or other material. *Patent abandoned.*

2245. J. T. SMITH. *Improvements in electric cables.* Dated Oct. 8, 1858.

This consists in the use of a corrugated metallic tube as the conductor for the passage of the electric current, such corrugation being either in unconnected indentations directly transverse to the axis of the tube, or in helical convolutions of one or more helices. *Patent abandoned*

2246. E. BIRCHLEY. *An improved construction of cartridge.* Dated Oct. 8, 1858.

This relates to a method of making ball, shot, and blank cartridges, sufficiently strong to permit of their being carried and handled without liability to injury, and yet admit of their giving way or bursting under the pressure of the thumb and finger of the sportsman or soldier when the discharge of the powder from the case into the barrel of the gun is required. The patentee employs in the construction of the powder chamber two different qualities of fabric, which shall have the one the property of comparative tenacity or strength, and the other of weakness or fragility. These substances are so arrranged as to give strength to the cartridge, and yet permit of its readily yielding to pressure. *Patent completed.*

2247. F. W. GERHARD. *Improvements in the manufacture of aluminium and sodium.* Dated October 8, 1858.

The patentee proposes to use as heretofore the double chloride of sodium and aluminium, or the double fluoride of sodium and aluminium known as cryolite, or both of these substances combined. These substances, when subjected to furnace heat in presence of the proper equivalent of sodium for ensuring the separation or extraction of the aluminium in a metallic form are covered with a layer of fused chloride of sodium, or of a mixture of this substance and cryolite, or of the slag or scoria resulting after aluminium has been extracted, and thus prevent the destruction by ignition of sodium, and consequently obtain a greater quantity of aluminium. In carrying out this part of the invention he employs a reverberatory furnace having two hearths one above the other, or two reverberatory furnaces or crucibles, one higher than the other, which communicate by an iron pipe or discharging passage. He claims the process of pouring the melted substance in the upper furnace or crucible over the contents in the heated lower crucible or furnace, by which means a greater quantity of metal can be obtained. *Patent completed.*

2248. A. E. GALLIARD. *Making self-supplying portable fountains to play water or water perfumed.* Dated Oct. 9, 1858.

This consists, 1, in the application of india-rubber, gutta-percha, or gum-elastic, employed as springs to press the water in a hollow cylinder. 2. In the application to this system of the leather cap or plunger employed in the manufacture of the moderator lamps. This cap is employed with another similar cap in india-rubber, gutta-percha, or gum-elastic 3. In the simplification of this sort of machine by the suppression of the rack and pinion and wire spiral spring, replacing thereby the india-rubber, and cord rolling round as upon a windlass. The improvements are not completely described apart from the drawings. *Patent completed.*

2249. C. E. BULL. *An apparatus for containing and preserving articles of value from loss or damage in cases of shipwreck.* Dated Oct. 9, 1858.

This invention is not described apart from the drawings. *Patent abandoned.*

2250. J. TATLOCK. *Improvements in electric telegraphs, and in telegraphic cables or conductors for the conducting of electricity in submarine and underground telegraphs.* Dated Oct. 9. 1858.

Here instead of employing the earth or water for half the conductor, the inventor employs two wires, which he separately incloses in gutta-percha. The invention also relates to electric telegraph indicators and is designed for better developing the power of the electric circuit. The inventor takes two wires each from the conducting wire, and laps one over each side of the magnetised needle, leaving room for the needle to oscillate inside the coil. It also relates to telegraphing by transmitting the electric current always along the same conductor, and allowing it to return along the other conductor. In this case he uses three batteries or currents. *Patent abandoned.*

2251. L. HOPE. *Improvements in electric telegraph cables.* (A communication.) Dated October 9, 1858.

Here the conducting wires are first coated with india-rubber or gutta-percha, in combination with sulphur. The wires are subjected to heat so as to produce the change in the india-rubber or gutta-percha known as vulcanisation, the conducting wires are then further coated with gutta-percha, &c, and the cables are then completed with a coating of wires or other materials as heretofore. *Patent completed.*

2252. W. CHOFFS. *Improvements in the manufacture of fabrics by bobbin-net or twist lace machinery.* Dated Oct. 9, 1858.

This relates, 1, to so combining transverse weft threads, working from selvage to selvage, with longitudinal bobbin and warp threads in bobbin-net or twist lace machinery that strips or stripes of lace or other weavings may be made side by side longitudinally of the fabric. It also relates to forming fabric of the kind referred to with the pattern of a zig-zag character, the pillars or meshes being bent serpentine, zig-zag, or angular by the bobbin and warp threads forming such pillars or fabrics whilst twisting with each other, being caused to travel out of their ordinary straight lines or courses, and being held together by passing through other warp threads. *Patent completed.*

2253. J. B. PASCOE and J. R. THOMAS. *Improvements in condensing and gassing smoke, which are applicable also to forcing and drawing water, propelling ships, and drawing and forcing air to be worked with animal, water, steam, or air power.* Dated Oct. 9, 1858.

This consists in drawing the air and smoke from any distance to any given point, passing it through the machine, turning it into gas or into water; if into water it is to be used as manure. In propelling ships the inventors take the water from the bows of the vessel, pass it through the machine, and discharge it at the stern in as large a column as may be required. *Patent abandoned.*

2254. J. SCRIMSHAW. *Improvements in pumps.* Dated Oct. 9. 1858.

This consists principally in making force pumps of various descriptions to throw one continuous stream of air, water, or any other liquid, and can be used instead of a bellows or air pump. *Patent abandoned.*

2255. A. MILLER. *Improvements in locomotive steam engines.* (A communication.) Dated Oct. 11, 1858.

This relates to a simple and effective mechanical arrangement for varying the action of the blast-pipe of locomotive steam engines, so as to suit its effect to the varying kinds of work which the locomotives have to perform. *Patent completed.*

2256. J. HOLROYD. *An improvement in the knives used for shearing woollen cloths, and cloths made of wool, and other materials.* Dated October 11, 1858.

This consists in grooving, indenting, or incising the spiral cutting knives, or the fixed blade, or both, used in cloth shearing machines, so as to produce a serrated cutting edge thereon. *Patent completed.*

2257. C. F. VASSEROT. *Improvements in constructing reflectors.* (A communication.) Dated October 11, 1858.

The patentee coats the surface of the glass on which it is desired to produce a reflecting surface with a salt of platinum or palladium mixed with a suitable vehicle, and also with a flux, and exposes the glass that is so coated to a heat sufficient to reduce the metal, and, at the same time, to cause the flux to run over and combine with the surface of the glass. *Patent completed.*

2258. J. SAXBY. *Improvements in apparatus for working signals on railways.* Dated October 11, 1858.

This consists of apparatus for the working of signals on railways by the engine or vehicles passing. The engine wheel in passing is made to depress a lever placed at the outside of the rail, which lever working on a centre, and at the same time rising at the other end, disengages a sliding bar which governs machinery for adjusting the lamps and signals to the position for showing danger, when it becomes fixed until relieved by a lever and chain connected with the signal-box. *Patent abandoned.*

2259. J. BEATTIE. *Improvements in locomotive and other steam engines.* Dated October 11, 1858.

The patentee constructs the fire-doors of the furnaces with a tube of iron fixed therein, and projecting externally and internally beyond the water-space surfaces, and he leaves another tube of iron to slide telescopically in such first-mentioned tube, the lower part of the sliding tube being cut away or perforated, so that the atmospheric air, which is admitted through openings in the door, may, when the inner tube is moved forward into the furnace, pass and strike the solid end of such tube, and be deflected according to the inclination or form of such end, or escape through the perforations in such tube on or over the fuel in the furnace; and he fits a tube of iron of smaller diameter into the end of the sliding tube, and such smaller tube is allowed to slide through an aperture in the fire-door, and so form a guide to the sliding tube. The air passes through the perforations in the smaller tube into the sliding one, which forms a chamber, and it thence passes as before mentioned; and in some cases he has two or more of such smaller tubes arranged in a suitable manner. The patentee also has one or both the plates for boilers and furnaces cut in such form that at such distance as may be desired there may be projecting pieces on one or both plates to overlap, and through which one or more rivets may be passed, in addition to the usual line of rivets, to hold the plates firmly together. *Patent completed.*

2260. R. COWEN, jun. *Improvements in dressing lace, and other fabrics made of silk, cotton, or other material, and in apparatus employed therein.* Dated Oct. 11, 1858.

The inventor winds the lace, &c., upon a roller, so as to conduct the same on to an apparatus which is so adapted as to stretch it any required width when it receives the dressing: from thence he conducts it through a hot chamber at such speed that from the time that the lace or other fabric entered in a wet or glutinous state, it shall, without friction or pressure being applied, come out perfectly dry, and in such a similar state as lace, silks, or other fabrics do when they are dressed or got up in the ordinary way. There is also an apparatus for steaming the lace, &c., previously to entering the hot-air chamber, so as to clear the fabric. *Patent abandoned.*

2261. J. L. and F. L. HANCOCK. *Improvements in implements for tilling, breaking up, or pulverizing land, for sowing seeds, and for thinning-out turnips and other crops.* Dated October 11, 1858.

This consists in constructing implements in which the tools employed are made to act gradually upon the land, so that each tool acting upon small portions of the soil, and each acting upon a separate portion, a great quantity is efficiently acted upon with much greater ease than if one tool only acted upon a quantity of soil equal to that moved by the several tools here employed. For sowing seeds the patentees form an implement with two or more depositors, which are so regulated as not to allow of more seeds being deposited from the whole number of depositors than now takes place from every single depositor as now constructed. For thinning out turnips and other crops, the implement carries a series of revolving discs, and between every two discs in the series they fit a knife or cutter. By means of this implement the plants may be removed from the drills, while the revolving discs will prevent the knives from cutting or dragging the roots of those plants which are to remain. *Patent completed.*

2262. J. ENGLAND. *Improvements in apparatus for cleaning the plates used in photography.* Dated Oct. 11, 1858.

The object here is to fix the pneumatic apparatus in clips which hold it firmly, whilst the glass, being fixed on the top of the pneumatic apparatus, and resting upon supports, is steadily fixed in a horizontal and favourable position to be cleaned without the photographer being obliged to hold it with either hand. *Patent abandoned.*

2263. J. PLATT. *Improvements in locks.* Dated Oct. 11, 1858.

Here the inventor constructs a lock with a key having a double set of wards or throwers, which take into fixed and stationary wards in the lock, and also act on levers or tumblers therein. The key has further a cross slit up the barrel or stem, which takes on to a cross fitted and turning in the centre opening, or eye of the keyhole. The lower set of levers or tumblers, upon which one set of the key wards or throwers act, is connected to bars which receive motion therefrom, and move in a direction transversely to the bolt of the lock, with which they underlock, being furnished with projections which are received in notches formed on each side of a chase or slot in the bolt which traverses on them when all accurately adjusted in position by the key. The other ward, or thrower of the key, acts on one or more levers or tumblers, on which the bolt travels. It also throws or shoots the bolt. This lock is made so that the key only turns in one direction, so that when the key is removed the bolt is shot so as to effect the locking action. *Patent abandoned.*

2264. J. NICHOLSON, jun. *Improvements in machinery for cutting and winding strips or shreds of steel, silver, or other metal used for ladies' dresses, measuring tapes, and other purposes, in which the use of strips or shreds of metal is required.* Dated October 11, 1858.

The inventor employs a strong framing of a suitable height, upon one end of which he places a feeding roller, and above it on the upper surface of the frame he places guide rollers and cutter guides for delivering the sheets of metal direct to the cutters. The cutters are circular, and are mounted on axles one above the other, the cutters being male and female. It is obvious that as the axles rotate, and the sheet is drawn between them, the pressure (which is similar in action to shearing) causes the sheet to be cut into strips. Other appendages are attached to, and used with, the machinery. *Patent abandoned.*

2265. A. VON SCHUTTENBACH. *Improvements in lamps.* Dated October 11, 1858.

The inventor employs a lamp, comprising a reservoir for oil, a resort for generating gas from the oil, and suitable pipes for connecting these parts with a burner, &c. *Patent completed.*

2266. T. RIDDELL. *An improved arrangement for sustaining window sashes and sliding panels.* Dated October 11, 1858.

The patentee avails himself of the elastic pressure of vulcanised india-rubber for maintaining sufficient friction of contact between the sash or panel and the frame, to ensure the retention of the latter at any desired position, and also to keep it from rattling in the grooves of the frame. *Patent completed.*

2267. M. STOW. *Prevention or securing the detection of alterations or erasures in bankers' cheques and other similar instruments, and the crossings thereof.* Dated October 11, 1858.

This consists in making a series of perforations which shall form an essential part of the crossing or other part of the cheque or instrument which is important to guard against alteration or erasure. *Patent abandoned.*

2268. W. E. NEWTON. *Improved apparatus for facilitating submarine explorations.* (A communication.) Dated October 11, 1858.

This consists in combining with the working chamber in which the explorers are to be placed a reservoir containing air compressed, so that the explorers may draw the required supply from the said reservoir, and to control the buoyant power of the apparatus. It also consists in combining with the working chamber one or more ballast chambers. It also consists in purifying the air inside the working chamber whenever it has become vitiated by the respiration of the explorers inside, by a shower of water. It also consists in combining with the working chamber, a pump, which communicates by its eduction pipe with the reservoir of compressed air, and by means of a flexible induction pipe with the atmosphere above the surface. *Patent completed.*

2269. J. F. SWINBURN. *Improvements in fire-arms.* Dated October 12, 1858.

This relates to double-barrelled small arms, and consists in employing a band of clip for connecting the barrels to the stock, whereby the necessity of heating the barrels for fixing on the loops is obviated. *Patent completed.*

2270. L. WRAY. *New and improved compounds for the coating or insulating of submarine electric telegraph wires, and which are also applicable to the coating or insulating of electric telegraph wires laid underground.* Dated October 12, 1858.

The substances which the patentee proposes to employ are, 1, vegetable caoutchouc (comprised under which designation are all those gum elastics produced by numerous South American, Oriental, and African plants, such as the

Digitized by Google

"Hevæa caoutchouc," the "jatropha elastica," the "ficus indica," the "ficus elastica," the "artocarpus integrifolia," and others), mineral caoutchouc (bitumen), or gutta-percha (under which designation are comprised the gummy or gum resinous products obtained from all the plants of the natural order Sapotads or Sapotea), or other gum elastic or gum resinous substances, or one or more of them together. 2, powdered flint, flour of glass, or other siliceous or aluminous matter, such as kaolin. 3, lac, or shell-lac, or other resinous substances, either one or more together. The inventor mixes these different substances in such varied proportions as he finds best adapted for the particular case to which he wishes to apply the compound. *Patent completed.*

2271. T. C. SHAW and F. H. COOPER. *A new or improved construction and mode of working engines by the agency of air or gases in conjunction with electricity for obtaining or producing motive power.* Dated October 12, 1858.

Here a reservoir is filled with condensed air, the condensation of the said air and its maintenance in a condensed state being effected by condensing pumps worked by the engine itself. The condensed air passes from the reservoir in an intermittent stream to a reaction or other engine, which is put into operation by the expansion and escape of the condensed air. On its passage from the reservoir to the engine, the air is exposed to an electrical discharge, whereby the elastic force of the air is much increased. *Patent completed.*

2272. W. JOHNSTON and W. ROSS. *Improvements in water-closets and taps or valves.* Dated October 12, 1858.

This comprises various improvements in the valvular mechanism of water-closets and in taps or valves, the whole having reference to improved modes or means of controlling or regulating the passage or flow of fluids. The invention is not described apart from the drawings. *Patent completed.*

2273. W. SMITH. *Improvements in transferring drawings or delineations in lithographic and zincographic processes.* Dated October 12, 1858.

Here the operator proceeds by primarily preparing a sheet of tracing or translucent paper, cloth, &c., with the transfer medium or materials ordinarily used in the preparation of transfer paper by lithographers and zincographers. The sheet thus prepared forms what may be termed a composite tracing and transfer paper, as it serves both purposes. This prepared sheet then answers as the medium for obtaining the first and only tracing used in the operation from the original drawing which is to be printed, the prepared sheet being fastened down upon the original drawing with its prepared face upwards. The drawing is then traced through, and on the prepared sheet with transfer ink, and it is then removed and applied to the stone or plate, the traced delineation being pressed down upon the face of the stone or plate. The removal of the sheet from the stone is effected by heating the back of it with hot water, and then taking up the sheet at one end and slowly pulling it off backwards. This process leaves the drawing upon the stone or plate ready for being inked up and prepared for printing in the ordinary manner. *Patent completed.*

2274. G. BEADON. *Improvements in the construction of ships, boats, rafts, and vessels for passing through water or through the atmosphere, or partly through the water and partly through the atmosphere.* Dated October 12, 1858.

It consists, 1, in constructing ships, boats, rafts, &c., with an outer jacket and open at the extremities, or with double sides, and with space between large enough to admit the wave or flow of the water or air displaced by the progressing end of a body in motion. 2, In forming the lower parts of vessels, including the patentee's conical bow-propeller, patented 21st Dec., 1852, in sections, in moulds, and putting the same together by tap-joints, bolts, and nuts. 3, In a boom or tail propeller for steering and propelling, and by its action keeping back the wake-water from following the vessel. 4, In constructing vessels with turntables for receiving masts with fixed yards, and working the same by gear-work, and hauling the sails out laterally. 5, In constructing the tubular bottomed vessels patented by the present patentee 21st Dec., 1852, with a moveable crane or Derrick, which the patentee raises or lowers between the sides or tubular bottom so as to project below the vessel to prevent the cables from injuring the conical bows or spiral propellers thereon when the vessel is at anchor. 6, In constructing tubular vessels with conical bows according to the patent aforesaid. 7, In constructing tubular bottomed vessels with openings at the sides above or upon pillars standing upon the tubular bottomed vessels, so that the waves may break through laterally. *Patent completed.*

2275. J. A. GASSE. *Improvements in railway brakes, and in apparatus for working the same.* Dated October 12, 1858.

This consists in constructing railway brakes, and apparatus for working the same, so that the brakes may be applied to every carriage throughout the train by means of rods, worked from either or both ends of a train, and connected between the adjacent carriages by means of two X levers, which cross each other, and are united at the centre by a pin or stud, around which, as a centre, they are free to move. These levers permit of the distances between the carriages being increased or diminished within reasonable limits without interfering with the action of the brakes. *Patent completed.*

2276. H. W. and G. CUTHBERTSON. *Improvements in lever purchases for ships' windlasses, pumps, and other similar purposes.* Dated October 12, 1858.

The inventors employ two short horizontal shafts, one above the other, the ends whereof work in bearings mounted on the top of the "pall-bit." On and about the centre of these shafts are placed two pinions working one in the other, and by the side of these pinions are fixed (also on the shafts) two cross heads; that on the upper shaft is hollow for the insertion of the lower handles, the lower one being solid and jointed or pinned at each end on to two vertical connecting rods by the side of the pall-bit. Thus as the power is applied to the handle and raised at one end, the reverse end of the lower cross head is also raised, and *vice versâ*. By this means they are enabled to increase the power four or five times more than by lever purchases. *Patent abandoned*

2277. M. SAUTIER. *Improvements in air engines.* (A communication.) Dated October 12, 1858.

The inventor uses moist air as the motive fluid, and employs an injection of steam to heat and at the same time saturate it with moisture, and an injection of cold water to absorb and remove such portions of the heat as the regenerator may not recover. *Patent completed.*

2278. J. PARKINS. *Improvements in securing envelopes, and in fastenings to be used therein.* Dated Oct. 13, 1858.

This consists in cutting and forming the envelope so that the ends of the side lappets may fold over each other upon the top of the lower lappet, and in cutting or piercing a hole through each end of the side and lower lappets, so that when folded together the holes may lie over and correspond with each other; also in cutting or piercing holes in the upper or seal lappet to enable it to receive the legs or pins of a plate or shield fastening, to be fixed thereto. *Patent abandoned.*

2279. H. PARKER. *An improved apparatus for the cultivation of land and other agricultural operations.* Dated October 13, 1858.

The peculiarity of this apparatus consists in the use of a portable steam-engine supported by two cylinders or sets of rollers, composed by preference of any number of short rollers revolving separately on circular axes. The one set of rollers is placed at or near to the front part of the machine for guiding, and the other set towards or near the aft part of the machine behind the centre of gravity, and perform the several functions of supporting the greater part of the weight of the apparatus, propelling it forward, and of simultaneously forking, breaking, and pulverising the soil as it passes over the surface of the land to be operated upon. *Patent completed.*

2280. R. RIDLEY. *Improvements in safety cages for mine shafts.* Dated October 13, 1858.

This consists of a peculiar combination of coiled or barrel springs and gripping eccentrics. The cage is fitted at its upper end with a pair of transverse parallel shafts, which carry at each extremity an eccentric. These eccentrics are disposed on each side of the conducting bars, and when brought into action or patially rotated by the coiled springs, they grip or lay hold of the conducting rods, and so prevent the descent of the cage should the rope accidentally break. *Patent completed.*

2281. W. H. TREACHER. *Improvements in respirators.* Dated October 13, 1858.

This respirator is constructed with an outer shell or plate, which may be covered with velvet or silk; at a small distance behind this outer shield the inventor places a similar plate, and brings both plates together at their ends; along the centre of, and between, the plates he fixes a partition which shuts off all communication between the top and bottom of the plates. In the back plate he cuts two slots, one above and the other below the partition, and over these slots he fixes, upon slight springs or blades, thin pieces of metal, one to each slot. These pieces of metal carried on the blades form valves, and he makes one to open inwards and the other outwards; he covers the space between the outer and inner plates with perforated metal both at top and bottom; and for convenience of wear, he applies a perforated metal screen at the back of the inner plate, and pads the screen to make it fit over the mouth. Where desired, he places powdered charcoal or sponge, moistened with any purifying agent, in that chamber to which the valve opening inwards is fitted. Thus air is inhaled through one chamber and exhaled through another, consequently the air exhaled is not again drawn into the lungs. *Patent abandoned.*

2282. A. G. BRADBY. *Improvements in connection with collars, ties, or other like articles of dress.* Dated Oct. 13, 1858.

This consists in combining a collar with a tie, scarf, ribbon, bow, or other like article of dress, so that the two together shall form one article of dress complete in itself. *Patent abandoned.*

2283. A. BENDA. *Improvements in the manufacture of models of the human and other figures, to be used as toys, for tuition, and for other purposes.* (A communication.) Dated October 13, 1858.

This consists in constructing models of the human and other figures, by forming the limbs and other parts of the same separately, and combining them by india-rubber or other elastic strips or cords. Models made in this manner are susceptible of being placed in various attitudes and positions, and may be used for toys, for tuition, for artistic composition, and for other purposes. *Patent completed.*

2284. J. BRADY, sen., and J. BRADY, jun. *Improvements in wheels and wheeled carriages to be propelled by steam, horse, or other power, and in apparatus for retarding the same.* Dated October 13, 1858.

This relates, 1, to a mode of constructing wheels of solid blocks of wood so connected together as to be of great strength; 2, to a construction of cast iron naves for wheels. It consists in constructing the wheel in sections composed of blocks of wood, so that when the blocks are brought together the grain will be from the centre to the circumference. It relates, 3, to a mode of mounting wheel-carriages, and of adapting thereto a portable railway. It also consists in coating the springs of carriages with gutta-percha, india-rubber, &c. Also, to means of retarding the progress of carriages, by adapting to some part of the axle-tree a drop-lever or bar with a kind of shoe or solid bent-up end or crank piece, which will act on the periphery of the wheel. *Patent completed.*

2285. J. C. OLLERENSHAW. *An improvement in cotton-gins.* (A communication.) Dated October 14, 1858.

The object here is to increase the capacity of the "roller gin," and the improvement consists in the use of a feeder bearing and working on centres below, and extending upward nearly to the line of contact of the two rollers, the upper end of the plate having a small curved ledge upon it armed at its front edge with teeth, and having a vibrating motion towards and from the bite of the roller, for detaching the seeds from the cotton and also assisting or feeding the cotton to the bite of the rollers. It further consists in using in connection with the feeder-plate a plate or comb provided with teeth, and having an endwise or lateral motion outside of and just below the bite of the rollers, together with the motion forward and back in common with the feed-plate by which the reeds are rippled, cut, and thrown off from the cotton as fast as the cotton is stripped from them by the action of the rollers and ledge on the feeder-plate. *Patent completed.*

2286. H. LIDDLE and J. BOOTH. *Certain improvements in machinery or apparatus for polishing and finishing yarns or threads.* Dated October 13, 1858.

This apparatus consists of a cylinder secured upon a shaft mounted in the centre of a framing, having its periphery clothed with fibre, and segments or tubes of india-rubber forming a series of "beaters." Upon each side of this composite cylinder, the "hanks" of yarn are distended in a vertical position, between two pairs of rollers which have a suitable arrangement of screw and bevel gearing for stretching the yarn; the cylinder is driven by a band and pulley upon its shaft, and motion is transmitted to the yarn pulleys by a worm and worm-wheel in connection with a train of spur and bevel gearing, which is so arranged that either one side of the machine or the other may be thrown out of gear by a lever and catch to remove the finished yarn without stopping the machine. The cylinder is to be driven at about 400 revolutions per minute, the high speed causing the cylinder to act as a fan and to dry the yarn, and the rapid action of the bearers upon the yarn effects the object of polishing and finishing. *Patent abandoned.*

2287. L. COWELL. *Improvements in apparel affording the means for preserving life at sea, and to prevent accidents to persons casually immersed in water.* Dated Oct. 13, 1858.

Here the garment is made of double or doubled or folded waterproof material, or the ordinary material lined with such manufactured waterproof material, so that the same may be inflated by the wearer, by blowing through an aperture having a spring valve therein. *Patent completed.*

2288. C. COWPER. *Improvements in the manufacture of articles of hard vulcanised india-rubber and gutta-percha, and similar gums.* (A communication.) Dated October 14, 1858.

In the first place the india-rubber, &c., is prepared for hardening in the usual manner, and is placed in the mould made of cast tin. It is then subjected to the action of steam or hot air. It is then removed from the heat, and the mould is removed from the india-rubber, &c. Any blisters or holes on the surface are now moistened by a liquid compound of india-rubber or gutta-percha, and are filled up and smoothed with the original compound, and pressed again in the mould. The parts of the mould are then pressed firmly together by screws, and again replaced in the heat. It is then again removed from the mould, and if the shape be perfect the article is placed loosely in a box without the mould. The box containing the shaped articles is then closed hermetically, and exposed to the heat until the articles are completely hardened. *Patent completed.*

2289. A. GORDON. *Improvements for manufacturing cast iron, steel, and wrought iron.* (A communication.) Dated Oct. 14, 1858.

This invention comprises, 1, a method of purifying and gradually decarbonizing pig or cast iron, or the iron as it runs from the blast or smelting furnace, so as to convert it at pleasure into malleable cast iron, steel, or wrought iron; 2, a method of obtaining steel or iron directly in a furnace or cupola charged with alternate layers of ore or mineral suitably prepared, and charcoal; 3, a method of substituting for the combustion of the coke usually employed, or charcoal, the combustion of coal or wood in the manufacture of iron and steel. This specification is very voluminous. *Patent completed.*

2290. J. R. SMITH. *Improvements in apparatus for propelling boats and vessels.* Dated October 14, 1858.

According to one modification of the invention a horizontal transverse paddle-shaft is fitted up in bearings near the boat's bow. This shaft has a paddle-wheel at each end, working in the usual manner, and it has upon it a toothed pinion, by which it is geared through a train of spur-wheels and pinions, with the shaft of a ratchet wheel, which shaft works in bearings a little abaft the paddle-shaft. The train of gearing is so arranged that one turn of the ratchet-shaft gives a considerable number of turns to the paddle-wheel shaft. The ratchet-wheel is actuated by a pawl and detent arrangement in connection with one end of a long working lever disposed lengthways and horizontally in the boat, the length being as great as the boat will conveniently allow. The party working or propelling the boat is seated in the stern, so as to be within convenient reach of the after end of the great lever, and by working this lever up and down in a vertical direction he actuates the ratchet movement, and through it and the gearing the paddle-wheels. *Patent abandoned.*

2291. T. INGRAM. *Improvements in means or apparatus for signalling between the parts of a train of carriages.* Dated Oct. 14, 1858.

The indicator used as a signal may be a bell or other means and is operated by a suitable cord, wire, rope, &c., continued from the part or parts of the train carrying the signal to the part or parts where it may be desired to operate such signal. *Patent completed.*

2292. W. CLARK. *Improvements in tanning hides, and in apparatus employed therein.* (A communication.) Dated October 14, 1858.

This consists in causing the tanning liquid to penetrate through the fibres of the skin, 1, by applying the pressure of a column of tanning liquid; 2, by a vacuum, which two processes can be employed either jointly or separately. *Patent completed.*

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, MAY 27, 1859.

THE ENGINES OF HER MAJESTY'S SHIPS OF WAR.

In adverting once more, and for the last time, to the Report of Admiral Ramsay and Messrs. Nasmyth and Ward on the engines of Her Majesty's ships of war, we have next to notice the discussion which they introduce upon the amount of steam power that can with most advantage be placed on board such ships. In order to place the matter fully and conveniently before our readers, we have printed upon another page the whole of the committee's remarks and of the Surveyor of the Navy's reply.

This very important subject, which the most experienced naval architects and engineers feel unable to grapple with satisfactorily, is very flippantly entered upon by this steam committee,—"many mistakes appear to have arisen "in making the calculations for ascertaining "the exact amount of steam power required "for any particular ship, &c." We may say at the outset what the Surveyor of the Navy says in another place, viz., that the inferences which the committee have drawn from a certain table of resistances (supplied, as he intimates, by Mr. J. Scott Russell), are altogether vague and useless. This is saying nothing, of course, against the table itself, which, if properly used, would be valuable, although it is found difficult to reconcile it in some respects with other recorded facts; but it was never intended to settle of itself the important question to the solution of which it is here applied. This table was deduced, we may say in passing, by Mr. Scott Russell from experiments made in an entirely novel manner, and with very great care, and from both these causes they might well be expected to differ from many of the data before in our possession. Premising this we may add that with the whole of the practical replies given by the Surveyor we fully agree, and we recommend them to the careful consideration of our readers. We would, however, proceed a little farther, and observe, that of the amount and variation of the resistance which ships meet with from the water but little is known; and to obtain it from trials of ships in the Royal Navy nothing, that we are aware of, has been done for many years. At present matters stand thus:—Engines of a certain horse power are given to a ship in accordance with the principle mentioned by the Surveyor in his reply, and when completed, the ship is tried at the measured knot. During the trial, indicator diagrams are frequently taken, and the mean speed of the ship, from several runs, is carefully registered. If the speed is considered low, the ship is set down as a faulty piece of mechanism; there can be nothing wrong with the engines, for the indicator diagram settles that question, and all screws are assumed to be equally efficient. Now, supposing the work of the engines to be correctly measured by means of the diagram, this work (when there is uniform motion) has to overcome the work done by the friction of the engines, shaft, &c., and the work done on the screw in its revolutions on its axis. The motion of the screw on its axis causes a thrust on its after part in the direction of the axis towards the fore part of the ship. This thrust is always equal in amount and opposite in direction to the resistance which the ship meets with in moving through the water. The thrust of the shaft on the ship is then the exact measure of the resistance. As to its amount for any ship at any speed, or its variation for the same ship at different speeds, we know nothing very definitely at present; and until we have suitable means by which this thrust may be measured, we shall be unable to decide with any certainty in any given case in which the speed attained was less than expected, whether the screw did its work well, and the resistance of the ship was great; or whether the thrust on the screw to push the ship was small; or, in other words, how much of the evil was due to the mal-formation forward, how much to that abaft, and how much to the screw. All the dynamometers which we have seen fail to give an accurate register of the mean thrust of the screw shaft on the ship; and until a simple and efficient dynamometer has been extensively fitted on board screw ships, we believe that we shall be unable to predict, with any certainty, the speed which a given ship will attain with a given amount of indicated horse power. We are, therefore, entirely at a loss to conceive why the committee should have introduced the table into their report, and drawn practical conclusions therefrom, unless it is that they have yet to learn the real position which the resistance occupies in the matter, and which we have above explained. All that has yet been attempted by practical men is to connect the primary cause with the effect;—the indicated horse power with the speed of the vessel. Referring to the tables of the results of the trials of H.M. ships, which we published on 18th February, 1859, there does not appear to be any very simple law connecting the indicated horse power with the speed attained; nor do we think it possible to "make a most accurate estimate of the dif-"ferences of resistance consequent upon dif-"ferent formations;" for, from those tables we find that many ships which would be called sharp, give bad results, and others which would be pronounced full, or even very full, give good results. The subject is beset with difficulties, and our present mode of gaining experience therein is very slow, and not at all sure; for the speeds of new ships often fall short of what might have been reasonably expected from them. It seems to us, therefore, to be very important to narrow our reasonings as far as practicable, by obtaining facts relating to the amount of the thrust of the screw shaft on the ship, so as to gain an additional step between the engine power and the speed. Could these be furnished to us, we believe that our advance in screw propulsion would be rapid, and our ground sure.

The next subject which engaged the attention of the committee is the use of the screw as a propeller. Various forms of screw propellers have at different times been proposed, they say, and various experiments made as to their respective utility; but from all these it does not appear that any form that has ever been applied to our men-of-war is superior, for the purposes of propulsion, to that of the common two-bladed screw, supposing, of course, that the proper pitch and diameter applicable to the vessel has been arranged. It has also the advantage of being more easily hoisted up than the three-bladed screw. The attention of the committee was directed to the consideration of the qualities of Griffith's screw, and as its pitch is capable of being altered, they recommend its use for determining the most suitable pitch, where a common screw is to be fitted for any particular ship. There is one detail which the committee recommend, more particularly as in the greater number of our screw ships the plan has been adopted, and found to answer well; it is, that the screw shaft should not draw in, but be fitted with a T-head. Proposals have been made also for increasing the convenience of stowage, and facility of moving, that very large screws should be made in parts; "but all these details are matters suited," say they, "for the consid-"eration of the engineers of the Admiralty, "rather than by this committee;" and there they are perfectly right. It is a pity that idea did not occur to them before. There is, however, one other point to which, as bearing upon the subject, they draw attention. All the evidence received shows that where a ship has very fine lines a coarse-pitched screw, with comparatively small diameter, gives the greatest speed; "and "as this result is evidently a great benefit, it fur-"nishes another example of the advantages that "ships with fine lines have over others." The committee cannot, they say, close their brief remarks upon this subject without strongly urging that the purchase of screw propellers should be at once abandoned, and that they should be all made at the Government factories. The brass screw, on Griffith's plan, intended for the Doris, cost £637 more than it could have been furnished for at one of our own factories. And taking a general average, it will be found that upon this article of steam machinery a saving may be effected by Government being their own constructors to the amount of at least 30 per cent. upon the price at present paid, besides the certainty of having the best articles that the country can produce. As the committee entered as far as we have shown into this question of screw propellers, we must say it would have been agreeable to us to have found that they had examined, and represented the merits of, the admirable feathering screw of Mr. Joseph Maudslay. In the same connection we may mention a fact which escaped our memory while penning our last week's article—viz., that a remark of the committee, on page 40 of their Report, in which they mention the "oscillating" and "double cylinder" engines together, is apt to mislead; for they incidentally state that the latter engine (and, by implication, that only) was patented by Messrs. Maudslay and Field; whereas it is well-known that the oscillating engine also was first successfully applied to marine purposes by Mr. Joseph Maudslay, who patented the arrangement, and employed it in numerous steam vessels before Mr. Penn or any other person used it as a marine engine. It is only fair that this fact should be borne in mind. A few trifling, not to say trivial, remarks on what they pompously call "economy of labour" (but which really treat of nothing more or less than a donkey engine or two), and on the "classification of engines," bring the committee to the "Summary," with which they conclude.

Before we finish with these gentlemen, however, we must repeat some of the very just observations of the Surveyor of the Navy, and say that it is greatly to be regretted that the committee, before making several of their recommendations and suggestions, had not obtained such information as would have been afforded them by the Surveyor and his department at the least intimation of their wish, and such as in some cases would necessarily have led them to conclusions the very reverse of those at which they arrived, and it is confidently believed in other cases to conclusions considerably modified. Why the committee did not follow this obvious and only course for obtaining authentic information to enable them to draw just conclusions, more especially since the Board's instructions required them to do so, and to have "frequent intercourse with the Surveyor," they alone can explain: it is sufficient to state the fact that they did not do so. If no instructions at all had been given, the Surveyor, who might be supposed from his position cabable of giving evidence of some

Digitized by Google

value on several of the matters which were investigated by the committee, should have been invited to do so; but he was not, although he more than once expressed his readiness to be examined. His minute which they insert in their proceedings, and which looks like a communication to them, was, he says, a copy of a minute which he had previously addressed to the Board, and which the chairman requested to have. The same remark applies substantially to the principal officers of his department. In selecting their witnesses, also, in many instances the committee did not take that course which is generally observed by committees appointed for similar purposes, and it is presumed never intentionally departed from. For instance, in their inquiries in regard to the forms of ships, the only persons whom the committee examined, with the exception of Mr. Scott Russell, were one master shipwright and two assistants, who, says the Surveyor, from their not having received a regular training in those branches of physical sicences which are necessary for the successful investigation of a subject far more complex than it appears at first sight, cannot be expected to be capable of giving so sound an opinion as those officers in the service who have had the advantages of a course of scientific instruction. In addition to what the Surveyor states, as we have seen, respecting the table of resistances, he adds that another striking instance of their over-hasty conclusions occurs in the case of the Diadem. "They record some person's opinions which cannot be entitled to much weight, while the opinion of Captain Cracroft, who had commanded the ship on a trial cruise, and who expressed that opinion to the chairman—a favourable one—is entirely omitted; his name does not even appear. On the other hand, the evidence of Captain Moorsom, who before he had tried the ship, recommended her stern to be cut off, high-pressure engines to be put in with a smaller screw, and other changes to be made, is duly recorded. Whether Captain Moorsom's opinion is right or wrong, it appears to have been formed and expressed so early as in a great degree to lessen its value. A somewhat similar course was pursued on another subject. A question to ascertain the readiness of manufacturers to construct engines on a plan different from their own, appears to have been put to all who were examined, with the exception of two, Messrs. Maudslay and Messrs. Penn. Possibly the committee thought it unnecessary to put the question to them, as they knew perfectly well what their answer would be. But such a mode of collecting evidence gives a one-sided appearance to their proceedings.

We think it right to expose these unjustifiable short-comings of the committee, lest any heedless and hapless reader, overawed by the authority which such a Report as that before us ought to possess, should mistake their blundering assertions for orthodox science. In conclusion, we will only say that while we have heard much, very much, spoken in condemnation of this silly production, we have heard no word pronounced in commendation of it.

THE CULTIVATION OF FLAX.

In a recent number we noticed the Prospectus of the National Flax Company, and, believing the extension of flax culture to be of great importance to the country, we again take up the subject.

The deficient supply of the raw material for our linen and canvas manufactures has for many years occupied much attention, and various projects have been devised with the view of increasing the quantity of home-grown flax, and improving its quality. The Royal Flax Society of Ireland has, ever since the year 1841, laboured zealously for the promotion and improvement of the growth of flax in Ireland. We have had Schenite's, Claussen's, Donlan's, Watt's, and other patent processes for the preparation of the fibre; yet for the last ten years the breadth of land under flax in the United Kingdom has been gradually decreasing, the entire quantity produced at home last year being only 26,599 tons, while 90,794 were imported. Our linen trade would at present absorb upwards of 150,000 tons of flax annually, and there is no adequate reason why the entire supply should not be produced from our own soil. We believe that most of the patented systems hitherto proposed have not been found successful when practically tested, and thus an amount of apathy and distrust has been created, which is much against the carrying out of any really sound and well-considered plan for promoting the culture and improving the management of flax. The National Flax Company intend to establish *Rettories* in suitable localities throughout the United Kingdom, purchase the flax from the farmers when grown, and make the preparation for the spinner a separate business. This we consider the right system to go upon, as flax will never be generally cultivated so long as the grower has to undertake the trouble of steeping, drying, &c., for the proper performance of which he has neither the requisite time nor knowledge. It seems to us that the drying machine (the patent right of which has been secured to the Company) renders the plan proposed to be carried out easy, simple, and certainly profitable. The apparatus to which we refer is thus described in the pamphlet issued by the Company:—"By the patent machinery, the flax, after being lifted out of the water, is passed at once in a continuous course through pressing rollers, and round cylinders heated by steam (being pressed against these cylinders by small carrying rollers) into fluted rollers, whence it is conveyed by hand all ready dried and broken, to be scutched. Thus the operation between the water and scutching is performed in less than a quarter of an hour. One machine is capable of drying sufficient flax to produce half a ton of fibre, and a quarter of a ton of tow, in ten hours." The processes of steeping and drying flax on the old system require from four to five weeks, and can only be done during the summer months; but by the patent process the whole can be accomplished in three days, while a superior article is produced, and the work can be carried on at all seasons, independently of the vicissitudes of the weather.

In the present aspect of European affairs the flax question assumes great additional importance, as complications may unfortunately arise which would shut up the markets of Russia, and thus leave us almost entirely dependent on our own resources, which in this respect are certainly ample, if properly utilised. We should, therefore, be up and doing while there is yet time. In every view of the case this is a truly national matter, the canvas used so extensively in our navy, and also in the manufacture of tents for our army, is made from flax of English growth. No one can say how soon the efficiency of both branches of the service may be put to the test, so that we should not neglect any of the necessary appliances, but, by developing the capabilities of the country for the production of flax, render our manufacturers, as far as possible, independent of foreign supply. The best argument, however, in favour of the National Flax Company is, the certainty of its paying a good dividend on the capital invested, as the calculations, based on sound data, show that a handsome return may be safely relied on. As we are in the habit of devoting a large portion of our space to the consideration of naval matters, we feel it our duty thus to bring forward the claims of this Company to general support.

GUNPOWDER EXPLOSIONS.

VERILY, gunpowder remindeth us of those old haradans who are brought before the magisterial bench, and who, after receiving just sentence for their deeds, incontinently hurl a shoe at the judge, or attempt to tear the jailor limb from limb. Scarcely had this Hecate of science received her well-merited verdict from the Hounslow jury, who pronounced her conduct "loose and dangerous," than she bursts out in a fury of revenge, blows up four mills, and flies at the poor fellow who would control her fury, and pursues him to the death.

This in sober earnestness is very sad! The verdict of the jury, which appeared at length in our columns of last week, is, although severe, only just, and we cannot see how anything less could have been arrived at. Those who read our former articles upon this subject may have been prepared for it; but with all our prophetic assumption, we confess we held on to a lingering hope that some one circumstance or other would crop out of the inquiry to mitigate or extenuate the fearful accusation of wilful neglect under which the proprietors and managers of these mills now labour.

Upon the subject of Government *surveillance*, the jury and the public appear to be somewhat in the dark. There already exist, to the best of our belief, official Inspectors of Powder Mills. We found this belief, in the absence of reference, upon the fact that a gentleman assuming to be a Government Inspector presented himself at the principal gates of the Hounslow Powder Mills upon the morning succeeding the late great "blow," and demanded admittance. This he was at first denied, but upon his threatening to send for a picket of soldiers from the neighbouring barracks and force an entry, the gates were thrown open to him. If we are not incorrect in this what a farce is here—a farce succeeding so deep a tragedy! A Government Inspector presenting himself at the door of the stable after the steed is stolen!—a Government Inspector whose face and person are totally unknown to the porter at the gate, although the latter has held that post for many years!

Professor Taylor's report is not yet printed. When this is done we shall return to the general subject of explosions of powder mills. With reference to the last accident we purpose maintaining a like reserve until after the coroner's inquest, feeling satisfied, as must our readers, that "Polvora" has been sufficiently answered by the events which have occurred since his letter was written without any further remarks from us.

GREAT GUN-MAKING AT WOOLWICH ARSENAL.

In completing our notice of the Royal Gun Factories at Woolwich, it is necessary to mention more particularly the arrangements for drying the moulds, the manner of preparing which it is hoped we have explained with sufficient clearness in previous papers. The drying stoves, as has been stated, are as nearly as possible 20 feet long, by 9 feet broad, and 8 feet high. They are covered with arches springing from cast iron girders, supported by the side walls. The stoves stand isolated, as it were, in the middle of the room or shop in which they are placed, and are built of 9-inch stock-brick work, bound together by bolts of iron—passing through external plates of cast iron—and nuts. The internal lining is composed of 4½-inch fire-brick work. The fire-places for heating the stoves are constructed on the insides of them, and at one end. They are sunk to about 18 inches

Digitized by Google

below the floor line of the stoves, and rise 6 inches above it. This prevents the fire, or rather cinders and ashes from it, reaching the floor. The fire-grate in each case is 3 feet 6 inches, by 2 feet 6 inches, and gets its supply of cold air through the ash-pit, which communicates with the external atmosphere. Draught is obtained by means of an outlet through the roof of the stove, the dimensions of this being 18 inches by 6 inches. The smoke from the stoves is carried away, not by a chimney, or chimneys, which would have disfigured in this particular instance the building, but through square wrought-iron pipes connected with the roof outlets of the stoves, and then passing down to underground flues which lead to vertical pipes running up the outer walls of the foundry. There are many practical mechanics who doubt the satisfactory action of downcast flues under any circumstances, and especially where combustion is slow, but at the Woolwich Factory, we can assure the sceptics, no difficulty is experienced with them. Well, then, the moulds are prepared, and the stoves are ready to receive them. Skeleton trucks, with four wheels each, so arranged with regard to guage, as to run freely in grooves commencing in the cast-iron floors of the stoves and extending into the shop beyond them, for a considerable distance—skeleton trucks of three or four *stories* in height, are now advanced to receive the several instalments of the great gun mould. Those parts of the mould which contain the greatest thickness of sand occupy the upper storey of each truck, because the temperature at the upper part of the stove will be the highest. In the 68-lb. gun, for example, the thickness of sand at the base ring is about 5¼ inches, and at the upper part of the "dead head," 4 inches, and, as may be supposed, the operation of drying so much material occupies a considerable time. It has been found by experience, indeed, that nothing less than 36 hours' submission to the properly-heated stove, will suffice to produce perfectly dry moulds. On one occasion, an attempt was made to expedite the drying of the moulds for a 68-lb. gun. Greater heat and shorter time was the theory of the Woolwich experimenters in these their "green and salad days." In the particular case to which we allude—and the lesson may profit others engaged in producing sound heavy castings—18 hours' drying was tried. The consequence was, that when the metal was run into the mould, steam was generated, and gases evolved to such an extent that, although there was a vertical column of fluid iron 17 feet in length within it, a terrible commotion ensued. The fluid iron surged and bubbled, and seemed to boil up for fully half an hour after pouring, and there is no doubt that, had not the mould been open at the top, and vent holes in the boxes very numerous, the combined explosive force of steam and gas would have rent the mould asunder, and scattered its contents with death-dealing force among the experimenters. In spite of the phenomena observed at the casting of this gun, it was turned; and presenting then to the eye no defect, bored and finished. In the proving operation, however, it went to pieces at the first round; and the short drying process has not, we believe, been repeated.

Supposing that the mould, of which we have been previously speaking, is sufficiently baked, it is next drawn from the stove, and by means of the crane removed also from the truck. Three or four corresponding portions of the mould are now bolted together, and lowered into the casting-pit, this being formed of wrought-iron plate ½ an inch in thickness, and being 20-ft. deep, 20-ft. long, and 8 ft. broad; and the remaining parts of the mould also bolted together quickly follow, and united make the whole complete for the reception of metal. The kinds of iron most suitable for great-gun making, the furnaces for melting that iron, the means of pouring it, and the method of preparing the patterns and moulds for the purpose, have now been given, and it only remains to be said that castings of the size in question are allowed to remain undisturbed for three days; that from the excellent character of the "blacking" used at the Arsenal, and described in our last, the castings then present as smooth a surface as that of a Paris kid glove, that scarcely any trimming is required even opposite the joints of the moulding-box, and that the loss in weight of iron used in the furnaces as compared with iron produced in the shape of guns, is 5 per cent. So much as to the production of heavy guns; the boring and turning operations have not been described, because similar manipulations are familar to our practical readers. The war pressure has increased the addition of further means and appliances to the Royal Gun Factories, and it is certain that the rate of production from them cannot be too much increased at this "rugged and awful crisis."

MARINE ENGINE-ROOM TELEGRAPHS FOR HER MAJESTY'S NAVY.

WE are much pleased to know that a series of experiments with these valuable instruments, and very important acquisitions to steam-ships, more especially to ships of war, has lately been going on at Sheerness for some time, under the direction of Captain Halsted and the steam-reserve. The operations and trials have been severe, in order to test the accuracy and working of each of several competitor's inventions, and to afford grounds for a report to the Lords of the Admiralty upon their relative efficiency; when we take into consideration the number of lives and valuable property dependent upon the efficient and accurate working of such telegraphs, especially in cases of emergency, it is of vital importance that every means should be taken to secure the most simple, substantial, and reliable instrument. The arrangement for proof was a day set apart for a trial of each inventor's apparatus, when reported ready for proof by themselves to Captain Halsted. The mode adopted to prove them consisted of the engine-room dial being divided into eleven segments of the circle, each segment graduated into seven divisions similar to the "minute" marks of a clock dial, thus making 77 divisions. The centre of each segment is accurately found, marked with a spear head, or arrow, intended for the index hand to stand at, when the motion of the needle to the point is "perfect" on being worked by the captain or pilot on deck, by the deck dials. The next graduated mark to the right is termed "good to the right;" the third mark is termed "indifferent;" and the fourth mark "bad." The same description applies to the left of the *arrow*.

The trials of each telegraph consisted of some hundreds of moves, as previously arranged on a tabulated form for this particular test, and were carried out by Captain Halsted on deck with each deck dial, two deck dials being necessary in a ship of war, one in each hammock netting, at the gangway or bridge. The officials below in the engine-room marked the working of each move of the hand on the dial. It may be interesting to some of our readers to give, as near as we could ascertain, the result of each inventor's telegraph on the days of trial. Without troubling ourselves with intermediate degrees of merit, we may say that the greatest number of "perfect" marks was attained by Mr. Thomas Suffield's (of Bermondsey-wall, and Fenchurch-street) instrument, which registered no less than 600 such marks. Mr. A. P. How's (London) came next, with from 350 to 400. Mr. Hornsey's (Southampton) followed with considerably less than 200, and Mr. J. Allen's (London) last with about 150. Of "indifferent" or "bad" Suffield's, and that alone, registered none at all.

It will thus be seen that the Suffield's telegraph had a very decided and great advantage. Having obtained the above information we waited upon Mr. Suffield in order to obtain particulars of his invention, when he in the most candid manner exhibited to us the whole apparatus in a full-sized working model; and in justice to the inventor, we must say it is an exceedingly simple and reliable working piece of mechanism. The arrangement of it throughout has evidently been made by a person of great practical experience, and we do not in the least wonder at its marked superiority. Mr. Suffield, as we learn, has recently opened extensive stock premises at 116 Fenchurch-street, for the convenience of shipowners, captains, engineers, and others, and the engine-room telegraph will, we presume, speedily be placed on view there.

THE EFFECT OF THE INTRODUCTION OF THE ARMSTRONG GUN ON NAVAL ARCHITECTURE.

BY CAPTAIN J. GARDINER FISHBOURNE, R.N.

(*Continued from p. 334.*)

THE above is fully confirmed by experience, as may be perceived by reference to the following table,* which shows that the widest ships with the least proportionate mean draught are the most uneasy—that is, roll quickest and deepest.

No. of Guns.	Name.	Length.	Half Breadth.	Mean Depth.	Diff. of 4 and 5 Col.	Character.
		ft.	ft. in.	ft. in.	ft. in.	
116	Queen	204	30 0	25 3	4 8	Uneasy.
120	St. Vincent	205	26 9	25 3	1 6	Very easy.
121	Trafalgar	205	27 6	25 3	2 2	Easy.
90	Albion	204	30 0	24 4	5 8	*Very uneasy*
90	Rodney	205	27 0	24 8	2 4	Easy.
80	Superb	180	28 6	24 7	3 11	Uneasy.
84	Canopus	183	25 6	23 10	1 9	Very easy.
80	Vanguard	180	28 6	24 0	4 6	Very uneasy
131	Marlborough (Sc.)	245	30 6	25 6	5 0	
91	Agamemnon (Sc.)	234	27 6	23 6	4 0	
	Birkenhead (Pad.)	210	18 6	17 0	1 6	Very easy.

The old French ships are in marked contrast and show the recognition of a principle in designing.

No. of Guns.	Name.	Length.	Half Breadth.	Mean Depth.	Diff. of 4 and 5 Col.	Character.
		ft. in.	ft. in.	ft. in.	ft. in.	
120	.....	209 0	26 9	25 11	0 11	Very easy.
86	.....	193 6	25 5	23 9	1 8	"
50	.....	173 0	22 5	20 2	2 3	"

The Albion rolled through 49° to one side, and somewhat less to the other side, and thirteen times in the same time and under the same circumstances that the Rodney rolled only *eight* times and 27° one way, somewhat less the other.

On a different occasion from the above, the Queen was observed to roll 20° and 7° and *seven* times in the same time and under the same circumstances that the St. Vincent rolled only *five* times and 13° and 5°; usually the St. Vincent was only shutting her first lower deck ports when the Queen had shut all hers and was commencing to shut her skuttles, which were 18 inches to 24 inches higher than her ports.

The Queen has also been observed to roll four times while the Trafalgar rolled but once.

Nor can these motions be said to have been due to the inequalities of the solids near the load water-lines, as has been asserted, for the Agamemnon, Hecate, and the Queen, very nearly so, have their sides perpendicular at that part; indeed, the Queen was originally laid down as a Trafalgar.

If, on the supposition that moving the centre of gravity would mitigate the evil of quick rolling, weights were raised in the Queen, Albion, or Superb, as a consequence they would roll deeper, but that fault is already too great; and if weights were lowered quicker rolling would ensue, but this is already too quick.

It must be observed also, contrary to what might have been expected from considering the effect of weights alone, notwithstanding their third deck, which, with its guns, must have amounted to 350 tons, situated say 25 feet above the centre of gravity, the Queen and St. Vincent were easier, and rolled less deep than vessels of

* *Limited as this table is, it shows the value of statistics*, which are dangerous only in ignorant hands. The contrast drawn above is between sailing ships, simply so, and screw vessels; yet, without controversy, the latter kind should be proportionably deeper.

Digitized by Google

their own type and nearly similar dimensions, viz., the Albion and Rodney respectively, principally because of their greater immersion, the Queen, partly because of her fuller body below. This view is endorsed by the reports of their Captains. Captain Lockyer wrote: "Albion rolls quicker perhaps for want of ballast, and her rolling has *increased* since the ballast and shot have been removed, and the ship *lighter from want of water and provisions.*" And Captain Corry wrote of the Superb: "Her rolling is quick, and in proportion to Canopus as 3 to 2, which in light airs, with any swell whatever, renders her very unsteady, and makes it *difficult to take accurate aim with her guns.*"

More recently the Agamemnon, when she had the Atlantic cable on board, with a swell abeam, and very little wind, rolled 20° to starboard, and 12 to port in 9·4 seconds. It must be added, that this was stated to have been due to the fact of the cable having been stowed too low; a sufficient contradiction to this, however, is, that the obvious consequence of raising the weight would have been to have increased the extent of the roll, just in proportion as it reduced the rapidity; on the subsequent cruize, but during bad weather, the vessel having been lightened 5 inches, and having had 200 tons of cable placed on the upper deck, lurched to upwards of 40°, and completed her roll in 10·3 seconds. The American frigate Niagara, on the first occasion, was said "scarcely to roll at all," while the Agamemnon was rolling both deeper and faster, and yet she had the greater portion of her moity of the cable stowed very high; consequently, if the effects described were due to the position of the weight alone, she would have rolled deeper but not so fast. This ship, however, as she discharged the cable, rolled more, and considerably by the time she arrived near Newfoundland, when she had discharged the greater part of the cable. Admitting some small portion of the difference between the rolling motions of these two ships to have been due to the difference in their dimensions, yet the principal cause was the large mean breadth of the Agamemnon, and the comparatively small mean breadth of the Niagara, as compared with their respective draughts of water, which in the first cruize was equal; the difference of mean breadth being due to their difference of form. If dimensions necessarily make a vessel easier, it may be asked why the Albion was so much less so than the Canopus. The owner of a yacht, and one of the best informed on the subject that I have met, says, "The rolling of my vessel has been strikingly diminished by lengthening her by the bow 8 feet," which he justly observed must have been in a great measure because her mean breadth was reduced.

It cannot be, as has been said, that the uneasiness of H.M.S. Agamemnon was due to the abstract fact of her being deep, for it is no uncommon thing for merchant ships to be much more so; thus, for instance, a ship of Mr. Green's brought a heavy cargo from Calcutta not long since, and was very easy.

The following dimensions will put this in a clearer light:—

	Length between Perpendiculars.	Half breadth.	Mean Draught.
	feet.	ft. in.	ft. in.
H.M.S. Agamemnon. . .	234	27 6	26 0
Mr. Green's Agamemnon .	244	18 0	19 6
White Star	285	22 6	24 4½

That is, the merchant vessels Agamemnon and White Star were proportionally deeper, the first by 3 feet, the second by 3 feet 4 inches, than the man-of-war, which was said to have been under extraordinary circumstances.*

Easiness is so important that its value should be further illustrated and enforced.

It is stated by Sir Howard Douglas that a second may elapse between the time of pulling the trigger and the time the shot leaves the muzzle of the gun. The arcs of roll of the Queen and St. Vincent being respectively 3° and 1½° in a second, we have but to suppose equally expert gunners, each to aim at the water-line of the other, and each to fire with a rising motion, the ships being 30 feet high and 400 yards apart, and the second alluded to to elapse, the result would be, assuming that there is no other cause of deviation, that the Queen's fire would pass over the hull of the St. Vincent, while every shot of the St. Vincent would hit the hull of the Queen; and yet the Albion, Superb, and Vanguard, rolled three times as fast as the Queen; how, then, could it be expected otherwise than that sister ships to these, as the Colossus, Exmouth, and others, should be otherwise than failures?

There is no reason to doubt but that the motions of the Marlborough, though less than those just named, would be faster than those of such ships as the St. Vincent or Trafalgar, as from the table the difference between her half-breadth and her mean draught is as 5 to 1·6, and 2·2 respectively.

As the deviation increases with the range, it were absurd to expect efficiency from ships that are so uneasy under not unusual conditions of weather; and if unfitted for smooth-bore guns, how much more unsuited to rifle guns, when, in addition to their great range, their shot take longer before they leave the gun.

The following is a more pointed illustration of the necessity for steady platforms. The Hecate and Antelope were anchored off the coast of Africa under very similar conditions; that is to say, they had about an equal proportion of provisions and water, &c., on board; the former was rolling 11° each way, and eight times in a minute—her commander states that her guns could not have been cast adrift and worked without danger.

He visited the Antelope officially, and found she was rolling but 5° each way, and about four times in a minute; her guns were cast adrift, exercised, and satisfactorily pointed at a target. The commanders of both vessels agreed that the Antelope could have destroyed the Hecate with ease, as the latter, at a moderate distance, could not have hit the former much oftener perhaps than once in fifty times.

In this case we have a vessel carrying only three guns, admitted to be superior to one a sixth larger, and carrying six guns.

It is evident that had the Hecate had 100 guns, and had rolled with equal rapidity, supposing only that the Antelope should have, as in the case in question she had, greater speed, her 100 guns would not have saved her from the fate predicted of the 6-gun Hecate; and if this case can occur with smooth-bore and comparatively short-range guns, how much more certainly would it do so were the Antelope's guns accurate and long-ranging rifles.

Rapid as was the motion of the Hecate, it was less than that of H. M. S. Agamemnon under favourable circumstances of weather, and only one-fifth that of the Albion; still it was at the rate of 3° in a second.

The form of the Hecate and Antelope, near the load water-line, was similar, so far as having equally vertical sides; consequently, the difference in their motions could not have been due to any inequality there.

I stated in a pamphlet last year that the Diadem would roll considerably; it is now reported that she and the Cæsar, 90, were lying at Greytown together, and that the former rolled twenty-five times, while the latter rolled only fifteen times. If these ships were under equal conditions as to the swell, and equal as to the proportion of coals, water, and provisions they had on board, then are we receding in our practice of shipbuilding, as the Cæsar is a much older ship, and a much shorter ship; whatever was the cause of the difference, it should be inquired into, and if possible removed, if not avoided, in any future ship.

In a paper of this sort, it were impossible to do more than clearly recapitulate the principles already enunciated.

The depth of water in which any projected ship is to be navigated should be taken as the limiting principle of the design; from that the immersed depth should be determined, and the vessel designed on that as a basis, and upon definite principles.

If a maximum fitness as a floating battery or effective sea-going ship, there must be a definite ratio preserved between the breadth and the mean immersed depth. If the horse-power is to be kept within satisfactory limits and a sufficient immersion obtained for an effective screw, the half-breadth should not exceed the mean immersed depth, and the centre of gravity should be kept proportionably low; if a maximum result as to efficiency and economy, so far as form will effect it, a fine bow and suitable midship section should be added—slightly convex at the load water-line is the best form.

[The concluding portion of this paper, together with some remarks by Sir W. Armstrong with which it was followed, will be given in our next.]

* It has been objected that in a pamphlet which I printed last year I understated the draught of water of the Agamemnon, and to that extent undervalued her as compared with the Napoleon; this implies that the defects of the former were confined to deficient draught, and that those who objected to my view would have been content had hers been equal to that of the Napoleon. Now I, on the contrary, contend that her form also is defective in principle, just where the French have borrowed from us, viz., in giving undue breadth; and while, as I believe, she is superior to the Agamemnon, her breadth is still too great by several feet for her depth. I was contending for a principle, and took the most correct information at my disposal; the incorrectness of this, however, even if it had been greater, would not have affected the *principle*, and in the case in point the only thing that was grounded on the fact was the propriety of inquiry before any ships similar should be built—a course not without value whatever the facts may have been. I could have no wish to misrepresent, inasmuch as the fact, whatever it may be, "cuts both ways;" thus in the same pamphlet I argued that it was not an undue weight of cable that caused her to roll so deep and so rapidly: this argument gains considerable force by the admission that she was only 2 feet or 2 feet 6 inches more than her proper draught, instead of 4 feet, more or less a few inches.

Literature.

The Story of the Life of George Stephenson, Railway Engineer. Abridged by the Author from the Original and Larger Work. By SAMUEL SMILES. With Portrait and Illustrated Woodcuts. London: John Murray, Albemarle-street. 1859.

WHETHER the remarkable character of George Stephenson, or the work which he accomplished, or the manner in which the story of both is here told, be considered, there is but one judgment to be pronounced upon this book, and that is an unqualified approval. There is not a youth in the kingdom, whether high-born or low-born, who would not find in its perusal a healthy and elevating stimulus. The demand for the larger work, from which this has been condensed, has been so great that we are encouraged to believe that in this its cheaper form it will have an enormous circulation. We earnestly hope it may. Let no youth or young man who may read these lines omit to procure it; as a possession, if possible; if not, for perusal.

Things not Generally Known, Familiarly Explained. Second Series. A Book for Old and Young. By JOHN TIMBS, F.S.A. Author of "Curiosities of London," &c. London: Kent and Co. (late Bogue), Fleet-street, 1859.

THE merit of Mr. Timbs' first series of these popular explanations is well sustained in the present series. He is an unrivalled compiler, and this, his last book, is inferior to none that has gone before it. It contains authoritative expositions of old English manners and customs, old plays and pageants, English laws, privileges, &c., money, weights and measures, olden herbs and fruit, phenomena of life, funeral ceremonies, home proverbs, sayings, &c., weather-wisdom, pictures, and the care of them, inventions and discoveries, &c.

Recent Practice in the Locomotive Engine. By D. K. CLARK, C.E., and Z. COLBURN, C.E. Parts 5 and 6. Blackie and Son; Glasgow, Edinburgh, London, and New York. 1859.

IN the first of the parts before us Mr. Clark continues his discussion of coal-burning locomotives, and of recent practice with them, and then, in

Digitized by Google

pursuing the subject of the physiology of the boiler, treats of "heat-traps," such as Gooch's Venetian damper, Barran's cup-surfaces, &c. In the sixth Part he concludes this part of his subject by a few pages on safety-valves, feed-water, and steam. He next gives two chapters on "The Engine"—respectively headed "Details," and "Working dimensions and arrangement of engines"—and then makes way for Mr. Colburn, who commences his part of the work with an account of the historical progress of the locomotive in America. The plates in Part 5 illustrate a passenger locomotive, by Danforth, Cooke, and Co, Paterson, New Jersey, and a goods locomotive, by Alexander Allan, of Perth. Part 6 presents us with several locomotives, by Beyer, Peacock, and Co., Manchester. These plates are got up with that excellence of style from which Messrs. Blackie and Son never depart.

Lecture IV. *(with Appendices) of a Course on the Principles and Practice of Civil Engineering: delivered at the Royal Engineer Establishment for Field Instruction at Chatham.* By HENRY CONYBEARE, F.G.S., M.I.C.E. London: Office of the *Civil Engineer and Architects' Journal*, 13 Warwick Court, Holborn. 1859.

MR. CONYBEARE is known to the profession as an able and zealous man; but it is only by perusing these lectures of his that a just estimate of his industry and research is to be formed. Here, for example, we have a discourse embracing an elaborate discussion of the various sources of resistance offered to motion on railways, the proportion of the load insistent on the driving wheels that is available in traction, and the general conditions of maximum useful effect in the locomotive, and in steam engineering generally, these subjects being illustrated by copious references to all kinds of authorities, and to inventions of the most recent date.

The Carpenter and Joiner's Assistant. Parts 17 and 18. Blackie and Son: Glasgow, Edinburgh, London, and New York. 1859.

WE have only space just now to say that the high degree of merit which has characterized this publication from the beginning, is in no way abated now that the work is approaching its completion.

Instructions for the Management of Open Boats in Heavy Surfs and Broken Water; with Practical Hints for the consideration of Merchant Seamen, or others having charge of Ships' Boats; to which is appended Instructions for Rescuing Drowning Persons, and for Restoration of the Apparently Drowned. Issued by the Royal National Life-Boat Institution. Charles Knight and Co., Fleet-street. 1859.

HAVING given the title page of this little pamphlet (published at 3d.) in full, it only remains to say that it has been deemed so reliable and useful that the Lords of the Admiralty have authorized its circulation in large numbers throughout the Royal Navy. This is, we presume, a stronger recommendation of it than anything else we could say in its favour.

LIST OF NEW BOOKS.

Althan's Treatise on Medical Electricity, 8vo.
Busk's Rifle, and How to Use It, 4th ed., fc. 8vo.
Foster's Commercial Code of Signals, by Larkins, second edition.
Hoppus's Table for Measuring, new ed., oblong.
Stantial's Test Book for Students, Pt. 4, Physical Science.
Stephenson (George), Life of, by Smiles, post 8vo.
Tate's Key to Elements of Commercial Arithmetic, new edition.
Timbs's Things not Generally Known, 2nd series, 8vo.

The National Botanic Gardens, containing the great palm house, the old and new museums, the tropical aquarium, &c., and the royal palace pleasure grounds, flower gardens, and new arboretum, having been greatly improved and adorned, are now open for the season, every week-day from one o'clock till dusk. On Sundays, from two o'clock till six. Free admission to the whole.

Proceedings of Societies.

ROYAL AGRICULTURAL OF ENGLAND.

May 18.—A Weekly Council was held.—The names of candidates proposed for election were read. The Secretary of the Belgian Legation transmitted copies of the programme of the International Exhibition of Reaping Machines to be held at Brussels, under the auspices of the Central Agricultural Society of Belgium. The Hon. Leslie Melville laid before the Council copies of the prospectus of a gas apparatus adapted to lighting farm buildings and stables and private houses. Having had one in operation himself for a year he was enabled from personal observation to detail its success. He stated that an intelligent labourer could manage it, and that the cost of gas varied from 2s. 9½d. to 3s. 6d. per 1,000 feet, but of course subject to variation according to the price of coal used. Mr. Fisher Hobbs expressed his willingness to detail to the Council the result of his practical experience relative to the Turnip fly, and his success in lessening the ravages made by it. The Council expressed their hope that Mr. Fisher Hobbs would favour the Society with this statement at the Weekly Council to be held on Wednesday next, the 25th inst. Adjourned to Weekly Council, on 25th inst.

UNITED SERVICE INSTITUTION.

May 20.—A lecture was delivered in the Theatre of this Institution, Col. the Hon. Jas. Lindsay in the chair, by the Rev. Baden Powell, M.A., F.R.S., Savile Professor of Geometry, Oxford, on "Rotatory motion, and its application to obtain stability for astronomical observations at sea." The object of the lecture was to explain the principles, on which, recently, plans have been proposed and successfully tried, for obtaining a stable platform for an artificial horizon, and a support for a telescope on board ship. The principles of contrivances hitherto adopted were shown to be defective on mechanical grounds, as mere suspension generates pendulum motion. The rotatory principle applied in the "top" of Terson and of Troughton, as the centre of gravity is below, involve the same defect. This defect is obviated by suspending a revolving desk in gymbals accurately balanced on its centre of gravity on the principle of the gyroscope. Such a machine has been constructed and actually used by Professor C. P. Smyth, on his voyage to Teneriffe. It affords a support either for his artificial horizon (constructed by means of a spirit level), and when on a larger scale for a telescope, which may be applied to the observation of the eclipse of Jupiter's satelites, so valuable for determining the longitude, but without it incapable of being observed. A working model of the machine was exhibited.

SOCIETY OF ARTS.

May 18.—Sir John Rennie, F.R.S., in the chair. The following candidates were balloted for and duly elected members:—T. Battam, jun., S. B. Edenborough, W. Hancock, T. Harman, J. Hollingshead, H. A. Silver, Vice-Chancellor Sir W. Page Wood. The paper read was, "On the Relative Values of Coke and Coal in the Locomotive Engines," by B. Fothergill. The paper consisted of a statement of the results of a series of experiments which the author had made, and was designed to show, first, that coal was decidedly superior to coke in respect of heating power, and consequently more economical; second, that a plentiful supply of steam could be generated by the use of coal for working engines at high velocities, and for drawing heavy trains; third, that coal-burning engines could consume their own smoke; and, fourthly, that fire-boxes and tubes were more durable with coal than with coke.

MEETINGS FOR THE ENSUING WEEK.

MON.—*United Service Inst.*, Evening Lecture, at 8 p.m.
TUES.—*Royal Inst.*, "General facts and leading principles of Geological Science," by John Morris, F.G.S., at 3 p.m.
Inst. Civil Engineers, Conversazione.
WED.—*Geological Society*, I. "On the sinking for coal at the Shirecoaks Colliery," by J. Lancaster, Esq.; II., "Notes on the Geology of Southern Australia," by A. Selwyn, Esq., in a letter to Sir R. Murchison, F.G.S.; III., "Notes on Spitzbergen," by James Lemont, Esq., communicated by Sir C. Lyell, V.P.G.S., at 8 p.m.
THUR.—*Linnæan*, at 8 p.m.
Society of Antiquaries, at 8 p.m.
Zoological, General Business, at 3 p.m.
Chemical, at 8 p.m.
FRID.—*Royal Inst.*, Thomas Henry Huxley, Esq., F.R.S.
SAT.—*Royal Inst.*, "On Modern Italian Literature," by J. P. Lacaita, Esq., at 3 p.m.

REEVE'S PATENT REVOLVER.

THE utmost thought amongst military mechanicians is at present being exercised to improve upon the revolver—a weapon of vital importance to the soldier. Such attempts, while they sometimes display considerable ingenuity, give us, for the most part, merely novelty as their result. Mr. Charles Reeves, the eminent contractor for arms of the Toledo Works, Birmingham, has, however, patented a revolver which may not be passed over without comment. It provides greater strength where the recoil of the chambers take place, and thus fracture is prevented at that part. The action of the rod is likewise *direct*, but that which will insure the greatest amount of interest is to be found in the arrangement which permits its owner getting immediately at the whole of the interior of the lock's machinery for examination, cleaning, and oiling. This is certainly a feature of improvement, as the user may be assured from time to time that all is right without waiting for the disturbing cause, which may alone present itself at the moment which may determine life or death. Reeve's pistol can likewise be half-cocked for safety in loading, and secured in that position by an excellent bolt, thus preventing accidental explosion. It can be wholly cocked with the thumb in taking a deliberate aim, or the contents of all the chambers can be discharged instantaneously by the trigger; either of which operations can be performed without withdrawing the hand. The chamber revolves upon an axis which is removable at pleasure, but which cannot become displaced, as is too often the case in other arms of a like nature. Having thus briefly alluded to the peculiar merits of this revolver, we need not add that in the choice of a weapon of this character too much discrimination cannot be used; and every opportunity ought to be afforded by the seller for comparison, and, if it be possible, for a practical course of trial.

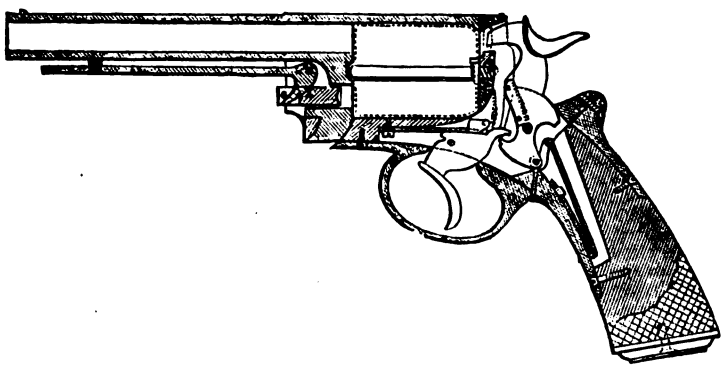
THE DEANE-HARDING REVOLVER.

ANOTHER revolver which has excited some attention recently is the "Deane-Harding Revolver." The engraving (next page) illustrates this weapon. The manufacturers (Messrs. Deane and Son) tell us that previous revolvers cannot be taken to pieces and put together again without difficulty. As a result of this, it not unfrequently happens that the owner, having taken his pistol to piecse for the purpose of cleaning, and having wearied himself with almost every variety of misplacement of the several parts in his attempt to put it together again, is compelled to resort to the gunmaker to make his weapon useful again. It was desirable that this objection should be removed. they say, and naively add, "but the difficulty of producing an entirely new arrangement without interfering with, or touching upon, one or other of the numerous patents already granted, was very great, independently of the natural obstacles which 'simplification' *per se* generally presents." The attempt, however, was made, and the present pistol is the result. The construction of it is so simple, in the judgment of the manufacturers, that it is almost impossible for any one having taken it to pieces to fail in putting it together again, in consequence of the whole of the functions being performed by the cock and the trigger; while from its simplicity and strength of parts, it is also not liable to get out of order. Another peculiarity in the new revolver is, that the barrel is removable for the purpose of being cleaned. "The readiness with which it can be detached, and its firmness and solidity when fixed to the body of the pistol, render the barrel and the frame, as it were, one piece—yet separable."

"In order to remove the barrel, it is necessary to turn the pendant part, forming the bolt to the cylinder, from right to left, until it stands upright above the top of the barrel, when the pin which joins the fastening between the barrel and the body may be withdrawn, and the two parts be separated by pressing them downwards in opposite directions (as if breaking a stick), the stock being in the left hand, and the barrel in the right. To replace the barrel,

Digitized by Google

THE DEANE-HARDING REVOLVER.



insert the hook upon its lower limb in the slot in the body intended to receive it, and the projection on the top of the body in the slot of the top strap of the barrel, when the bolt-pin can be returned to its place. To take the action (or lock) to pieces, take out the screws by which the stock is affixed. Remove the mainspring by placing the edge of a screw-driver under its lower extremity and pressing it upward. Take out the screws which hold the guard in its place. Unscrew and remove the trigger-spring with the lifter. Then the cock and trigger may be taken out by unscrewing their respective pins. When cleaned, return each part to its place in reverse order."

The facility with which this pistol may be loaded, by the use of the new Lever Ram Rod, which is at once simple and powerful, acting vertically upon the bullet, is also another new feature.

THE STEAM POWER OF MEN-OF-WAR.

By ADMIRAL RAMSAY, C.B., Mr. NASMYTH, and Mr. WARD.

[The following paper on "the Amount of Steam Power that can, with most Advantage, be placed on board of Men-of-War," and the reply of the Surveyor of the Navy to it, are taken from the Report made to the Admiralty on Marine Engines. Our remarks upon these papers will be found in our leading article.]

MANY mistakes appear to have arisen in making the calculations for ascertaining the exact amount of steam power required for any particular ship. The source of these mistakes has often been sufficiently obvious, and the greatest uncertainty will always prevail as to results, where there has not been the most accurate estimate of the differences of resistance consequent upon different formations of vessels, as well as taking into account the capability of the ship when fitted with an engine for carrying weight.

1st. Of these mistakes, some no doubt had their origin in the attempt to obtain great speed from ships where there has not been the proper formation for obtaining that speed. The ships may, from their capacity, have been quite competent to carry the weight of steam machinery put on board, but were not constructed for the speed.

Before determining the amount of steam power suitable for any particular vessel, a reference should be made to the conditions indicated by the following table:—

Suppose four vessels of the same size and displacement, but of different formation, the results of the resistance at two different rates of speed will be as follows:—

VESSELS.	RESISTANCE.	
	At 3 knots.	At 7 knots.
A. With as fine lines as a man-of-war can have.....	12·0	52
B. Lines not quite so fine.....	12·2	84
C. Still coarser.....	12·5	96
D. With lines the same as our old 44-gun frigates.....	12·7	129.

Now, assuming that the above table is correct, and there seems no reason to doubt its accuracy, it must be obvious that the error has been sometimes committed of putting too great power on board of our steam ships as at present planned.

The Diadem, with 800 nominal horse-power, although a noble ship, is quite a case in point. By reference to a table kindly furnished to this committee by Captain Moorsom, it will be found that in perfectly smooth water and little wind (force 3) it required an indicated horse-power of 2390, or in other words, nearly three times the nominal horse-power, together with a consumption of 60 tons per day, to obtain 9·9 knots from the Diadem.

But it has been urged, although the committee do not admit the objection to be relevant, that although the Diadem, and vessels with similar lines, cannot be expected to attain to great velocity under steam alone, yet that, in the case of strong head winds, when slow speed can only be expected, they then are placed more upon an equality with ships which have finer lines than they have, and thus the great power placed on board of them becomes of essential use. The committee conceive that there must be a fallacy in the argument, as it would lead directly to the conclusion, that to have fine lines is a disadvantage to a man-of-war.

There is, however, another error into which the professional advisers of the Admiralty have sometimes fallen, and which the committe are desirous of noticing. In order to obtain great speed, engines of such large power, and therefore of such great weight, have been put on board that the vessels have been quite unfit to carry the weights allotted to them. In some cases also, from the small size of the ship, the steam machinery has occupied so much space that the vessel has lost much of its utility.

The projectors of such vessels seem to have forgotton that the length of a screw-ship may, under certain circumstances, be considerably increased without diminishing the speed; and in some cases, where the weight put on board is less in proportion to the increased length, and the immersed midship section being lessened, the velocity may be increased.

The following is an important example, to show that the length of a ship may be increased, that 300 tons more weight may be placed on board, the immersed midship section being unalterd, and yet that the speed may remain the same, with the same engines and boilers.

The Peninsular and Oriental Company's ship Canada, before being lengthened, was 280 feet long, and her trial at the measured mile in Stoke's Bay gave 12·5 knots. This vessel was lengthened 35 feet before the midship section, and on her second trial had 300 tons more weight on board than on the first trial. Her second trial took place on the 12th August, 1857, also at Stoke's Bay, and the speed of the Canada was then 12·45 knots.

It must not, however, be supposed, from anything that has been said upon the subject of placing great power on board unsuitable ships, that the committee are not desirous of guarding against the opposite extreme, namely, that of placing only very small steam power in ships, merely because they have not good lines of construction. A certain degree of speed for a man-of-war has now become essential; and in converting old sailing ships into screw steam-ships, the nominal horse-power that ought to be placed on board each ship must be carefully considered in reference to the size and lines of the particular case. For instance, from the size and formation of the Queen, it would probably be advantageous to place 100 nominal horse power more than should be placed on board some of the other line-of-battle ships that are being converted.

REPLY.—BY THE SURVEYOR OF THE NAVY.

It appears from the tenor of the remarks of the committee on the forms of ships, that they suppose there are some persons holding office in the Government service, and who, having made this subject their especial study, and being well acquainted with the dimensions, forms, and other elements of Her Majesty's ships, and of many others, as well as with a vast number of authentic facts relating to their actual performances, are not yet aware that fineness of lines is conducive to velocity, and essential to high velocity. Such an opinion, however, it may be confidently stated, is altogether erroneous.

The effect of fineness of form on velocity is universally admitted, and it has never been disputed.

All theoretical considerations show that this might be expected, and all experience proves it beyond the possibility of a doubt.

Then it may be said, why not carry the principle into practice? How far it has been carried is strikingly seen by a glance at the models of ships constructed during the last 10 years, and the propriety of going so fast in this direction has been questioned by more than one Board of Admiralty. At first sight it appears a simple question: it may be thought that to effect the object in view, it is only necessary to add a finer piece of structure to each end of a ship; but a moment's reflection will dispel this error; the displacement of the pieces supposed to be so added will not give buoyancy to support a tenth part of this weight; the necessary displacement must therefore be provided elsewhere; this can be found only in the middle of the ship, so that the ship must be also lengthened amidships sufficiently to displace a quantity of water equal in weight to the entire weight of this midship piece, in addition to 9-10ths of that of the other two: but this is not all, the temptation to put into a ship of such dimensions a heavier armament is irresistible, rendering necessary more men and more stores; displacement must be provided for all; in fact, a ship of the old form to be made like one of our recent designs, must have her length increased by one-half; her cost of construction would in consequence be half as much again, and her handiness under sail somewhat impaired.

It is no wonder, therefore, that propositions to build a frigate 50 feet longer than former frigates should be considered, debated, and reluctantly consented to, more especially as no honest man could say with certainty what would be the precise effect in point of speed, and in other respects, of such additional dimensions and alterations of form.

After a few good experiments have been made, which are now in progress, and a few great points, as it were, fixed for future guidance, it becomes an easy matter to predicate with some certainty the results of any subsequent and comparatively subordinate changes that may be required if they do not constitute a very peculiar combination.

A kind of law is thus established, which may be relied upon with certainty within its own limits, and even for some distance beyond them. This is the extent, whatever some may pretend to, of the means of extending our knowledge of this branch of naval architecture, and it is deeply to be regretted there is not much chance of our

Digitized by Google

getting any other help. Our proceedings must be based on experiments, and on experiments alone; hence the vast importance of those trials to ascertain the exact speed of our ships and of the power developed at the time—trials which some persons consider as matters of mere curiosity, not worth the time they occupy, and others as calculated, if not intended, to mislead persons into the belief that the speed thus realised is to be regarded as the ordinary sea-going speed of the ship.

This subject being of high importance, it may not be out of place to point out shortly how our ships have been lengthened, step by step, in order to give them finer lines.

	GUNS.	BUILT.	LENGTH. ft.	in.
Agamemnon	90	1852	230	0
Renown	90	1857	244	9
Bulwark	90	Building. 1858	252	0
Imperieuse	50	1852	212	0
Shannon	50	1855	235	0
Diadem	32	1856	240	0
Newcastle	50	Building. 1858	250	0
Ister	50	Building. 1858	270	0
Mersey	40	Built. 1858	300	0

It will thus be seen that our frigates have now reached the length of 300 feet.

In designing screw-ships for the navy, it has always been considered as essential that they should be capable of sailing well, of being readily manœuvred, and of steaming well.

Speed under steam may be obtained by means of length and fine lines; but until it shall have been satisfactorily ascertained that the great length which is necessary to obtain high speed under steam alone does not materially interfere with the ready performance of the evolutions which may be required of men-of-war under any circumstances, it would not be prudent to depart otherwise than gradually, and after sufficient experience, from the dimensions and forms of the ships which have been found to possess every good property.

Almost the first of the large ships designed especially for the screw were the Duke of Wellington, Agamemnon, and Imperieuse, when a considerable step was taken; the Agamemnon having been made 230 feet in length; the longest sailing two-decker being only 205 feet.

It being found that these ships sailed and worked quite as well as the ordinary sailing ships of the same classes, it was decided to make a further step in this direction; and, in consequence, the Renown was built of the still greater length of 245 feet, to enable her to receive larger and more powerful engines than the Agamemnon, and to give her finer lines with a view to increase speed under steam.

The trial of the Renown having proved so far satisfactory, it has been decided to take a yet further step by building the Bulwark, and other ships of this class, of the still greater length of 252 feet, for the purpose solely of making them of still finer forms for greater speed.

High speed under steam is, in the present day, considered of such paramount importance that no reasonable expense should be spared, nor means left unresorted to, which are likely to accomplish it, provided the sailing and other essential properties of ships are left intact.

But in still further increasing the length of ships there is another and very important consideration, whether, looking at the fineness of their extremities, and weight of their machinery, it will be possible to make ships built of wood of sufficient strength to retain their forms for any length of time.

It has always been felt that it is by means of experiment at sea chiefly that any reasonable expectations can be entertained of advancing the art of designing ships and their machinery; and, with this view, experimental trials of ships have been made from time to time when their services could be spared; but the absolute necessity for such experiments has been still more felt since the introduction of the screw, for this has rendered necessary an entire change in the size, proportion, and form of ships, in consequence of the enormous bulk and weight of their machinery and coals, and of their being required to sail well, to steam well, and also to behave well under sail and steam combined.

Far more complex and difficult considerations are thus introduced, and almost incompatible conditions required; in fact, so complete a change has been made in Her Majesty's navy within the last few years, that the former accumulated experience derived from the behaviour of sailing ships becomes comparatively useless as a guide for the construction of modern steam-ships.

Data, however, founded on the actual performance of these ships at sea are now fast accumulating, and it may be expected that the conclusions drawn from them, and from an elaborate comparison of the lines, and calculated elements of ships of different classes, will gradually but surely point out the nature of the improvements which are still needed, and the best mode of effecting them.

Immediately connected with this subject is that of the engine power which ought to be used. This is also an important question, and one involving difficult considerations, which experience and observation will alone help us to deal with satisfactorily. It by no means follows, that because a vessel carries a wave before her when urged to the utmost at the measured mile, she has more power than can generally be used advantageously. This is an exceptional case, and should not of itself be taken as a criterion of the proper amount of power required for general use.

A certain speed for every particular class of vessel may be regarded as essential, at which speed the power placed in her should be capable of propelling her under ordinary circumstances without difficulty.

The rule generally has been to place in ships of war as much power as the displacement and general arrangements connected with the necessary stowage of the ships admit of being placed in them, and in no instance has the amount of power so determined been reported too great by the officers who have commanded such vessels; but, on the contrary, complaints have been sometimes made of its being insufficient.

The committee, however, adduce as one instance of too great power being, in their opinion, placed in a vessel, the case of the Intrepid, which was taken out for trial by them at Devonport. Against this opinion may be placed that of Captain R. Drew, who commanded the Nimrod, a sister vessel, with the high boilers taken out to afford greater coal stowage, to adapt her better for making the passage to China. He says in his report, "In steaming head to wind in smooth water the ship behaves well, but against a swell her performance, from want of power, is very bad; she will only move two or three knots when a full-powered steamer would be making six and seven knots. Auxiliaries have at least their sails to depend on, but this ship is both auxiliary in steam and sail. I would recommend the high boilers being replaced, and the ship full rigged, which would make her perfect in both respects."

All ships of this class have since been more fully rigged.

The next case of too great power, in reference to form, is that of the Diadem. Her speed, when last tested at the measured knot, was 12 knots, which the committee regard as less than is due to the power, and that with a less amount of power, and finer lines, an equal speed would have been obtained. This may be true with greater length; but under the same length it would not be practicable, it is believed, to fine the ends of the vessel sufficiently to effect this object At the time when the design was made for this ship, a strong feeling was entertained against increasing the length of ships, both on account of the additional cost of their construction, and of the difficulty which might attend the working of them under sail, together with the greater dock and basin room they would require. These considerations have prevailed up to within a short period, to prevent the lengthening of ships sufficiently to enable suitable forms to be given them for attaining high speed, except with some sacrifice of power.

The Diadem it may, however, be observed, was designed originally for 600-horse power engines, and 800-horse power engines were subsequently ordered to be placed in her, because the French were then placing engines of this power in their 50-gun frigates of about the same length.

In order to form a better judgment of the capabilities of the Diadem, it might be well to compare her with the Euryalus, a frigate carrying a greater number of guns, but of about the same aggregate weight.

This ship has only 400-horse power, and the Diadem, in consequence, has a superiority in point of speed of nearly two knots, an advantage which, coupled with the longer range of her guns, gives her a superiority which cannot be questioned.

It may be almost unnecessary to observe that the disadvantage of expending a larger quantity of coals is only incurred when high speed is necessary to effect some important object beyond the range of the smaller-powered ship; at speeds within this range, the Diadem would expend no more coals than her rival.

In fact, the only important question is, is the Diadem a better ship with 800-horse power than she would be with 600, or any less amount of power?

It is assumed that few practical men would hesitate in answering this question in the affirmative.

The question raised in the last paragraph of the committee is not one of opinion, but of fact, namely, the internal capacities of the several ships referred to.

This was of course ascertained in the first instance, before any suggestion was made to the Board respecting their conversion into screw ships, and if the committee had communicated their intention of expressing their opinion on this subject, the necessary information would have been freely furnished to them, and they would thus have been prevented from making loose statements, so calculated at first to convey erroneous and unjust impressions, but afterwards to lessen the confidence which the statements and opinions of a committee generally command.

Instead of the Queen being capable of carrying larger engines than the other three ships, she is, in fact, the least capable; she has actually less available displacement than any of them, and less internal space.

The cubic contents of her hold below the orlop deck is upwards of 1,300 feet less than that of the Trafalgar.

"DELTA'S" PATENT CHEESE PRESS.*

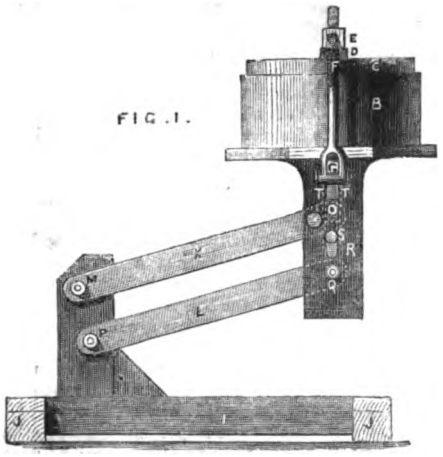
IN the new press, which is here arranged for a cheese press, but is applicable for any purpose where a press of moderate power is used, the simple mechanical arrangement and the absence of screws and appliances where an uncertain amount of power is obtained, is the chief argument for its recommendation. The precise force exerted may at all times be known and regulated, and after that it is entirely self-acting.

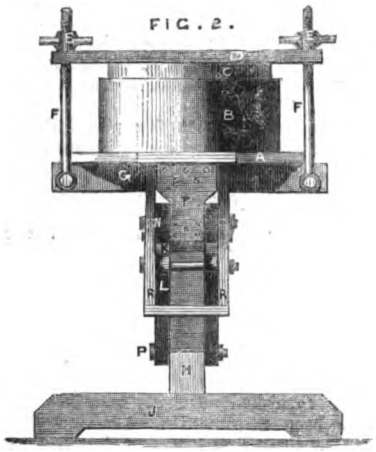
Fig. 1 is a side elevation, Fig. 2 a front elevation, Fig. 3 a plan, and Fig. 4 a diagram of its working. *A* is the table of the press on which is placed *B*, the hoop containing the cheese, and *C*, the cover fitting loosely within the hoop *B*; *D* is a crossbar which is screwed down upon *C* by means of the nuts *E E* on the screws *F F*, which are attached to the lower crossbar *G*. *H* is the framing of the machine, or upright fixed in *I*, which is kept in position by the feet or stretching pieces *J J*. Fixed to the upright *H*, by the pins *M* and *P*, are the two pair of arms *K K* and *L L*, the latter of which act merely as guides, while *K K*

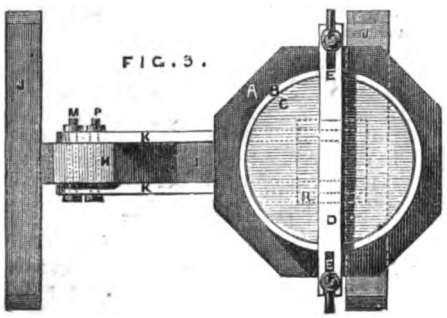
* The inventor and patentee of this apparatus wishes his name to be kept back.

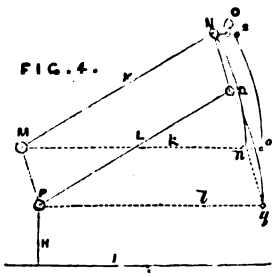
Digitized by Google

are double levers attached to the sides of the table brackets *E E* by the pin *N*. The slide piece *S* is joined to the crossbar *G* by the plates *T T*, and is acted upon by the pin *O* in the levers *K K*. Then, as the table *A* is depressed, the pin *O* forces the









slide piece *S* down, drawing with it the crossbars *G* and *D*, and therefore pressing the cheese.

In the diagram the levers or arms *K* and *L* are shown at an angle of 30°, and it will be seen that the length of *K* from *M* to *N* is the same as that of *L* from *P* to *Q*. *N* and *Q* being the pins by which they are attached to the table brackets *R*, and they thus form a parallel motion for the table *A*.

If a horizontal line be drawn from the point *N* while elevated, it will show the distance between *O* and O^2 to be one inch; then if the levers are placed in a horizontal position the short arm *n o* will have recovered the inch, which will consequently have been communicated to the cheese.

In the arrangement shown, the levers bear a proportion of 12 to 1, and in practice it is found that the weight is transmitted to the cheese in this ratio, added to the constant weight of the levers, table, &c., which is found to be equal to from four to six cwt.; then if the cheese, hoop, and cover weighs 30 pounds, the force exerted will be 3¼ cwt. nearly—the constant say 5 cwt.

Should this not be found to be sufficient a weight placed upon the table will readily make up the deficiency, as a seven pounds weight will give out a force of three-quarters cwt., and the weigh of the cheese determines the pressure to be given out by the levers. These may be made any length and proportion, but that here given has been adopted as giving the best range of the point *O*, being about 1¼ to 1⅝ inch.

The press is readily loosed, and when lowered the table serves as such to turn and trim the cheese upon; to obtain a fresh purchase it is only necessary to raise the table and screw down the nuts *E E*, when the range is again renewed. The weight of the whole is from 40 to 60 pounds.

A silver medal was awarded to this press a few days since, on the only occasion when it has been exhibited. Mr. R. Law, of Shettleston, by Glasgow, was the maker.

HALE'S IMPROVED WAR-ROCKETS.

FIG. 1.

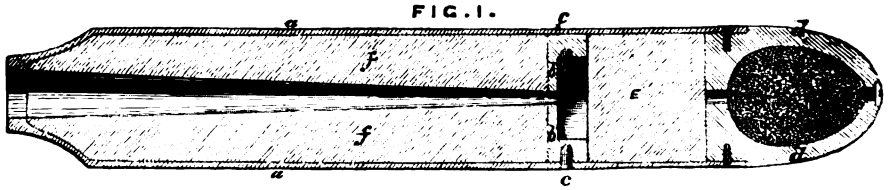


FIG. 2.

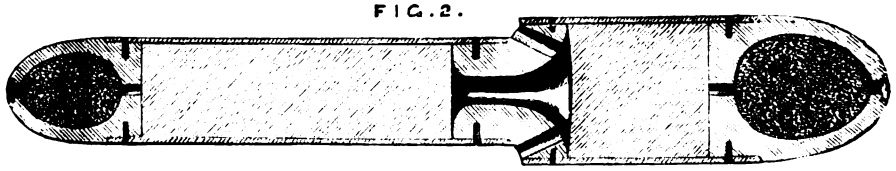

MR. HALE, the inventor of the well-known war rockets, is not idle in these days of preparation. He has just completed a patent for further improvements, the object of which is to ensure a more certain direction of the flight of rockets than can be obtained by any other arrangement hitherto made use of, and also for sustaining the case against the extra pressure which is produced in rockets constructed according to a former patent, dated January 11, 1844, wherein the bored composition has not only to be sufficiently long for supplying the gas to give the onward motion, but likewise for giving the rotatory motion, and a weight or plug was placed at the back for the purpose of bringing the centre of gravity towards the after end. But he has since discovered, as he tells us, that the application of the weight with the oblique tangential apertures at the after end causes the rocket to describe an orbit which more or less produces uncertainty in the direction of its flight; and to obviate this is one important object sought in these improvements. It is effected by dispensing with the weight at the after part, and instead of placing the tangential apertures at one end, he now arranges them in a plane as near as possible to the centre of gravity, between the bored part of the composition and that part toward the head, which is left solid, this being in the position of about the centre of gravity; and in order to give greater stability to the case he rivets in a cast iron piece in which the tangential apertures are formed. whereby solid composition supplies the tangential apertures with gas for giving rotatory motion about the rocket's axis. The bored composition is devoted only to giving the onward motion. Fig. 1 of the accompanying engravings is a longitudinal section of this improved rocket; *a a* is the cast iron case forming the body with the after end contracted to nearly the size of the main central hole; or a light cast iron end may be riveted into the tube in lieu thereof. This aperture is intended for the egress of the gas in the direction of the rocket's axis, producing the onward motion; *b* is a cast iron plate with a thick rim on one side which is riveted inside the case in such position that when tangential holes are drilled through the case, and through the rim of the plate, they shall all range in the plane of the rocket's centre of gravity, when the rocket is complete with the shell or shot in the head. The dotted lines *c c* indicate the centre of gravity; *d* is the shell showing the hole for the fuze; *E* is the solid composition between the shell and the plate *b*, which is intended by its construction to supply the tangential holes with gas for giving the rotatory motion, while the bored composition *f* supplies the central hole with gas for giving the onward or rectilinear motion. A small hole is drilled through the centre of the plate whereby a communication is obtained between the gas generated by the combustion of the solid composition and that of the bored part, so that the rotatory and rectilinear motion shall take place at one and the same time, the rotation being produced by holes formed in the direction of tangents to a circle described in the plane of the rocket's centre of gravity, to insure a steady motion during its flight. Fig. 2 shows a section of another form of rocket, with a shell at either end for ground firing at short ranges, and for which no rotatory motion is required.

An issue of tickets for the Crystal Palace Handel Festival at five shillings each has been announced. Seats for these will be provided in the north and south naves, and from the fact that the present orchestra projects considerably beyond that of 1857, and brings the principal singers and the band and chorus much more into view, there is no doubt but that the issue of these tickets will be appreciated. Concurrently with this arrangement, additional galleries have been planned, and raised stalls have been decided upon, on the site now occupied by the Italian orchestra From these seats the entire frontage of the orchestra (216 feet wide) is comprised within one glance. Considerable additions, principally unison stops, are being made to the Festival organ erected, and some gigantic steel kettle drums, far exceeding in size any yet in use, and some deep-toned brass instruments, are being built for the occasion.

Mr. J. Le Cheminant, of 39 Queen Ann-street, writes under date of May 19, 1859, as follows:—"To the Editors of the MECHANICS' MAGAZINE." Gentlemen,—Having noticed in your interesting and valuable paper of the 13th instant an advertisement of Mr. W. Gosling relative to a newly-invented gun and projectiles, I beg to inform you that the projectiles, as well as the hinged platform for the gun to slide upon, were patented by Mr. Wm. Hobbs, of 196 Piccadilly, on the 1st of September, 1858. This being the case, I felt it advisable to apprise you of the same."

LAYING-OFF; OR, THE GEOMETRY OF SHIP-BUILDING.

FIG. 23.

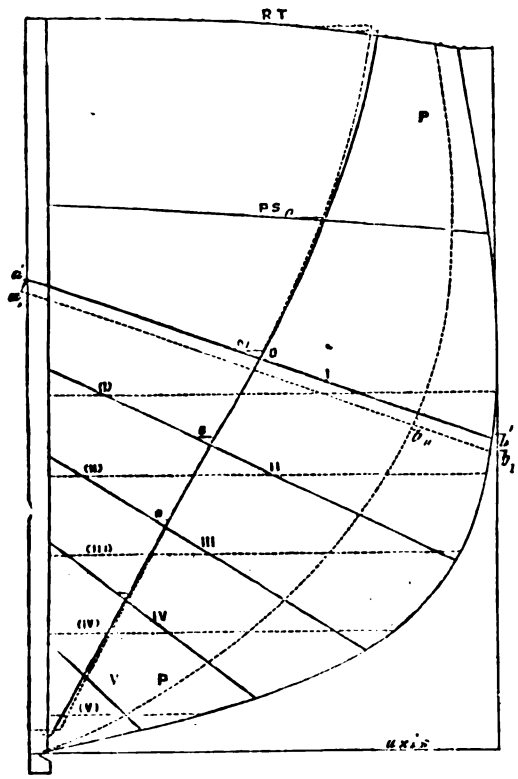

FIG. 24.

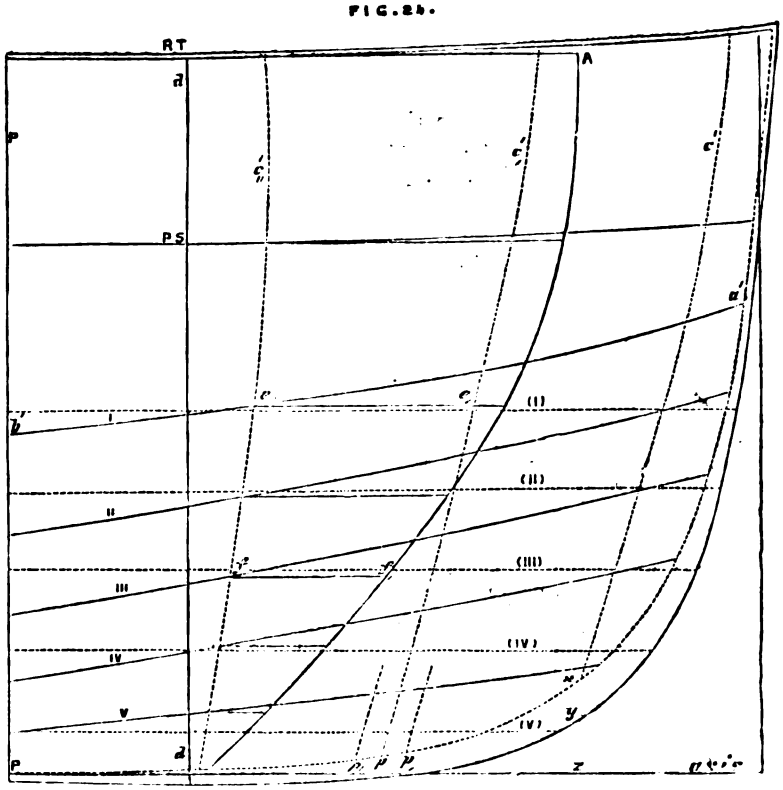


LAYING-OFF;
OR,
THE GEOMETRY OF SHIP-BUILDING.

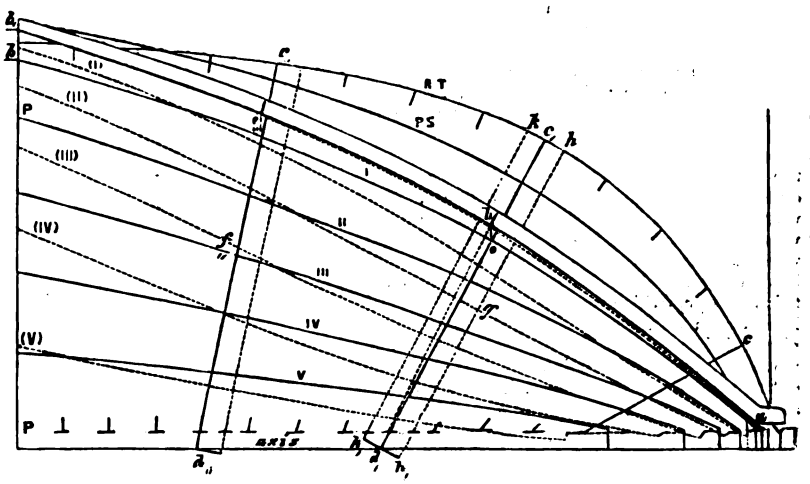
No. VI.

THE diagrams given above show on a small scale the various sections which have to be drawn on the floor for the purpose of laying-off the harpins and cant timbers in the fore body of a corvette. The sections marked (*I.*), (*II.*), (*III*), (*IV.*), (*V.*), in the three plans are level lines; and those marked *I.*, *II.*, *III.*, *IV.*, *V.*, are the projections of diagonals; these latter lines in Fig. 25 are called *level* diagonals, or horizontal ribbands. The line *P P* in the three plans is a vertical transverse section. *R T* is the rough-tree or upper boundary of the ship, and *P S* is another sheer line at the height of the portsills. The lines *x*, *y*, and *z*, in Fig. 24, are respectively the bearding line; the fore edge of rabbet of stem; and a continuation of the upper edge of rabbet of keel, forming the axis. The straight lines *c*, c_{I}, and c_{II}, in Fig. 25, are the horizontal projections of the joints of cant frames; *c'*, c_{I}', and c_{II}',* are the vertical projections of these joints in the sheer plan. The positions of all the joints of the cants in the fore-body are indicated in Fig. 25, but to avoid confusion, only three have been drawn. It may be necessary to repeat here what we have already said in describing the square frames, viz., the adjacent sides of the lower pieces in each *cant* frame touch each other, but between those of the upper pieces there is an interval of some inches. There is, however, an imaginary surface of contact from the bottom to the top of the frame in continuation of that formed by the lower pieces; this imaginary surface is called the *joint* of the frame.

To lay-off a harpin.—The line *I* is, as we have said, the horizontal projection of a diagonal line, and does not give the real shape of any section of the vessel. To obtain the shape of the section made by the diagonal plane *I*, or *a'b'*, the plane must be swung up about its trace upon the vertical plane through *a'* until it becomes parallel to the horizontal plane, the true form of the line

* Read *c*-dash, *c*-one-dash, and *c*-two-dash.

FIG. 25.



will then be found to be ab_1; to which the harpin mould may be made, as shown in Fig. 25. In order that the workmen may be able to trim the harpin, so that it may fay against the bottom, it is necessary to give them not only the mould to one of its edges, but also a number of bevellings; for which purpose the shape of the bevelling edge of the harpin must be obtained. The projection of the bevelling edge in the body is a straight line parallel to the moulding (upper) edge, and at a distance from it equal to the thickness of the harpin, as shown by the dotted line a_1b_1. Let us now suppose that the half of the ship is cut through by the planes $a'b'$ and a_1b_1, so that $a'b'\ b_1a_1$ may be a slice of the ship. Let this slice be supposed to be hinged in the horizontal line through a', and swung upwards: then when $a'b'$ becomes horizontal, a_1b_1 will also be horizontal, and if both the curves, viz., that of the moulding edge, and that of the bevelling edge be projected upon the horizontal plane from this position we shall be able to discover where the bevelling edge projects beyond the upper edge, or where the bevelling of the inside of the harpin is *under*; and also where the converse of this is the case, and the bevelling is *standing*. The dotted line in fig. 25, nearly coincident with $a\,b_1$ is the bevelling edge for that harpin. It will be seen that the distance from the *axis* of any point in the line $a_1\,b_1$ (fig. 23), after the planes have been swung up, is the same as its distance from the point a_1, because, after the revolution, the point a_1 lies in the axis. For example, the position of the point in which the bevelling edge intersects the vertical transverse section *P P*, is found by setting off on *P P* in the half-breadth, the distance $a_1\,b_{11}$ measured in the body. Having obtained the moulding and bevelling edges of any harpin, it is very easy to take the bevellings. If it is desired to get the bevelling at the joint c_1, measure square to the curve (fig. 25), the distance between the two edges, this will be the distance

Digitized by Google

(in this case) outside a "square" or right angle in the siding or thickness of the harpin.

It is sometimes convenient to "pitch" the *lower* side of the harpin at a definite height at the ship; to make this the moulding side, and the upper side the bevelling edge. In such a case the measurements for obtaining the bevelling edge in the half-breadth for the diagonal a' b' would be made on a line drawn the thickness of the harpin above it, and from the point in which a_1 a' produced upwards would meet this new line.

It is necessary to mark on the harpins—and, therefore, on the harpin moulds—the positions of the joints of the cants, to direct the workman in fixing the timbers in their places. To do this it must be observed that the *horizontal* projection of the point in which the harpin crosses the joint of a cant timber is the point in which the horizontal projections of the diagonal and of the joint cross each other. For example, o is the horizontal projection of this intersection in the case of the joint c_1 and the diagonal I, and is, therefore, the horizontal projection of the point we wish to mark; from which we know that, were the harpin in place, the point itself would lie *vertically* over the projection o. It must therefore be evident that when the diagonal plane with the harpin is swung up into the position a b_1 the point sought would describe a circle in a plane at right angles to the axis; and would be found after the revolution in a line o o', drawn through o at right angles to the axis; and, of course, also in the expanded diagonal a b_1; the point o' is, therefore, that which should be marked on the mould. We conclude, from this, that the proper positions of the joints on the harpin mould, may be found by squaring up from the level to the expanded diagonal the points in which the level diagonal crosses the joints of the cants. The line c_1 d_1 gives us, as we shall see more clearly presently, the direction of the sides of all the timbers composing the frame $c_1 d_1$; this *direction* also it is necessary to mark on the harpin mould as a further guide to the workman. It will be seen that if the harpin mould were down in its proper place instead of being rabatted upon a horizontal plane, it would appear to be coincident with the line I; and the direction of the line c_1 d_1 across it would be the direction required. Suppose, now, that while the harpin mould is thus inclined downwards, a batten were laid on the diagonal plane coinciding with the line c_1 d_1, and therefore indicating the required direction upon the harpin mould. Then when the diagonal plane with the harpin mould were swung up to the horizontal the batten would appear to lie no longer in the direction d_1 c_1 but in the direction do', for the extremity d_1 of this line d_1 c_1 (which may be considered to be the intersection of the cant plane with the diagonal plane) being in the axis of motion would not move, but every other point in d_1 c_1 would move out at right angles to the axis. The point o would, as we have before seen, move to o', and the batten which would rise with the plane, being compelled to pass through this point whatever position it may occupy, must lie in the direction d_1 o', which would therefore be the direction sought, and which it is necessary to rase upon the mould. *Practically—to mark off the joints of the cants*, square up from the level diagonal to the expanded diagonal the points in which the former cuts the joints; then stretch a batten from the points so obtained to those in which the respective joints cut the axis, and rase them across the mould. The moulds for the harpins at the *sheer lines* are made to the horizontal projections of these lines, although there is a slight error in doing so, because of the double curvature of the lines; they should properly be expanded lengthwise. Frequently, however, the harpins at these heights are not made to the sheer lines but to level lines got in for that purpose. The bevelling edge for either a sheer or level harpin is obtained in exactly the same way as the moulding edge; and the position and direction of the cants upon the mould may be marked at once from the half breadth.

To lay off a cant timber. Let us now endeavour to obtain the true shape, and the bevellings of the timbers on each side of the joint c_1 d_1. These operations are always performed in the body plan, but for the sake of illustrating the principle adopted, we shall first show how the true shape may be obtained in the sheer. The curve c_{11} is, as we have said, the vertical projection of the curve in which the surface of the ship, on the timbers, is cut by the joint plane of the cant frame c_{11} d_{11}. This projection is obtained by considering that the points in which the *vertical* projections of two lines cut each other are immediately over the points in which the *horizontal* projections of the same lines cut each other, by which consideration we are able to obtain points in the vertical projection of c_{11} d_{11} on the lines *I, II, III, IV, V,* (*I,*) (*II,*) (*III,*) (*IV,*) (*V,*) and on *PS* and *RT*. Let it be observed now, that c_{11} d_{11} is at the same time the projection of the curve of which we have to find the true shape, and the horizontal trace of the cutting or sectional plane. We may imagine that this sectional plane is a door hinged in a vertical line through d_{11} on the vertical longitudinal plane, and that the true shape of the section is drawn upon it. If we swing this door upon its hinges until it coincides with the vertical longitudinal plane, or, in other words, if we rabat it upon the sheer plane, the true shape will be seen upon that plane. The supposed hinge will be, in the sheer plan, a line d d, found by erecting a perpendicular upon the axis from d_{11}. When the revolution takes place every point in the curve of the section will remain at the same height as its projection in c_{11}', but its apparent distance from d d will increase. Thus the point, of which e is the vertical projection, *i.e.*, the point in which the required curve cuts the diagonal a' b', will in the revolution move along a horizontal line e e_1, until its apparent distance from the axis is the same as its real distance, which we know to be d_{11} e_{11}, fig. 25. Again, the point in which the required curve cuts the level line *III*, the vertical projection of which is f, would be found, after the revolution at f_1, in the same line, but at a distance d_{11} f_{11} from the axis. Similarly the new positions of all the intersections in the projected line may be discovered; and the curve A e f_1, found by joining these points, will be the true shape required, to which a mould may be made. A bevelling edge could be obtained in a similar manner, and the bevellings found for the timbers, but as the section is always in practice laid off in the body and not in the sheer we shall proceed to show how that may be done. Imagine that the door c_1 d_1 is turned about the vertical hinge through d_1 until it is parallel to the plane of the body, and at right angles to the axis, then the projection on the body plan of the required curve will give its true shape. It will be seen that during the revolution the height above the axis of any point in this curve will remain the same as the height of its projection; while its distance from the axis will increase until it becomes equal to that of its horizontal projection (fig. 25) from d_1. For example, the point in which the cant section cuts the level line (*II*), and of which g is the horizontal projection, will be found in the line *II* (fig. 23) and at a distance from the axis equal to d_1 g. We might thus, by means of a number of level lines, obtain as many points in the true or rabatted curve as would be needed for describing the curve on the floor. This would be, indeed, the more simple mode of operation, but another consideration comes in, which is, that we need to know the positions of the diagonals on this curve for the purpose of giving bevellings at them, and that we may know, with regard to the harpins, the heights of the several portions of the cant frame; so that on the whole it is less trouble to obtain the points in the curve from the diagonals at once than from the level lines.

Observe how this is done. The point o is the *horizontal* projection of the intersection of the required curve with the diagonal (Fig. 25); the *vertical* projection of this intersection in the body must lie in the vertical projection of the diagonal, and at the same distance from the axis as the horizontal projection. Measure therefore the perpendicular distance of o from the axis (Fig. 25), and set it off "square" from the axis in (Fig. 23) to intersect the diagonal I; the point o_1 so found, is the vertical projection of that point in the curve of the cant, of which o is the horizontal projection. Similar points, o o, being found on the other diagonals, and on the sheer lines, the curve joining them would be the vertical projection of the joint edge of the cant. But this curve is not got in upon the floor, as it is only necessary to know the points o' o, &c., which we have already obtained. From these points short straight lines, called *liftings*, are drawn out horizontally, and it will be clear that the points in the true curve of which these points are the projections, will be found after the revolution in the horizontal lines so obtained. The distance from the axis of the points in the rabatted curve will evidently be the distance of their horizontal projections from d_1, so that if we measure d_1 o, and set it off from the axis in (Fig. 23) along the *lifting* o_1, we shall obtain the point O in the true curve. Finding points in this way at the sheer lines and diagonals, we are able to get in the required curve, which is shown by the drawn line in (Fig. 23). Its ending at the bearding line is obtained as follows: measure in Fig. 24 the height p of this ending above the axis, and draw a *lifting* at this height in the body; then measure along d_1 c_1, Fig. 25, the distance out from d_1, at which the joint of the cant meets the side of the deadwood as indicated by the dotted line. Set off this distance from the axis in the body, on the lifting just obtained; the point thus found is the ending of the joint of the cant at the bearding, and as the cant timbers cut off at, and butt against the side of the deadwood, it is also a point in the heels of the timbers composing the cant frame. When the distance between the timbers on each side the joint is not great, the shape of their moulding or joint edges is assumed to be the same as that of the joint, but when the opening is large there would be too much error in such an assumption, and the shape of the section of the vessel is obtained at the joint side of each of the ranges of timber composing the frame instead of at the joint—in this case the range of timbers are said to be laid off as single timbers. Having obtained the line at which the mould is to be made, it is necessary to get in a bevelling edge. For this purpose another section of the ship is taken parallel to that already obtained, and at a distance from it equal to the siding of the timbers. Thus, pursuing the case we have chosen, in which they are laid off from the joint; h h_1 is the horizontal trace of the plane taken for bevelling the timbers *before* the joint, and k k_1 that of the plane for bevelling the timbers *abaft* it. The points in the vertical projections on the body plan, of the sections made by these bevelling planes, are found in just the same way as those of the section c_1 d_1, and liftings are drawn out therefrom in the same manner. Now imagine the slice of the ship contained between the planes h h_1, k k_1 to be turned round with the plane of the joint about the hinge through d_1. Then, when this slice becomes parallel to the body plan, the points k_1 and h_1 will lie in the axis, so that the real distances of the points in the bevelling edges to be set off on the liftings from the axis in Fig. 23, will be the distances, measured before the revolution, from h_1 and k_1, and not from the *axis* in Fig. 25. We have shown in the body, by a dotted line, the form of the bevelling edge in the section h h_1, obtained in this way. The practical mode of operation is to take off on a batten the shortest distances from the axis of the intersection of h h_1, with the level diagonals and the sheer lines in Fig. 25; set these off horizontally from the axis in Fig. 23, so as to discover the corresponding points in the diagonals and sheer lines, and draw the liftings. Then measure along h h_1 the distances of these same points from h_1, and set them off from the axis, in Fig. 23, on the liftings. The endings of these bevelling edges on the bearding line are obtained by drawing liftings in

Digitized by Google

Fig. 23 at the heights of p_1, *i.e.*, of the points in which the projections of the bevelling edges meet the bearding line. Then, for the distance to be set off along these liftings, measure the distance to the side of the deadwood in Fig. 25 from k_1 for the *foremost* edge, and from k_1 for the *after* edge.

ON TIMBER FOR SHIP-BUILDING.

(Concluded from p. 319.)

AUSTRALIA is the next country to which I shall ask your attention, and which already furnishes us with "iron bark," one of Lloyd's first-class woods—a distinction we all thoroughly understand. This vast island is unfortunately extremely deficient in navigable river and in water communication generally, and whether this deficiency can in any manner be remedied by the formation of railroads or tramways intersecting the enormous forests of valuable timber that exist (not far inland), is an important question, now occupying the serious attention of very eminent and influential men in our metropolis, and which I shall have occasion to refer to again, although very briefly. Besides iron bark the only Australian woods that have any classification at Lloyd's are the stringy bark and the blue gum, and these are in the fifth-class. For a variety of reasons, however, I propose confining myself entirely to the woods of Western Australia in its more southern parts. Those especially interesting to the ship-builder are the tuart, the jarrah, the blue gum, and the morrell. The "tuart" is a noble timber tree, growing in tolerable abundance on the coast, peculiarly in the limestone districts. Planks are sometimes obtained ten feet wide, and it is said to be peculiarly adapted to the building of ships of war, as it is most difficult to split, and is not liable to splinter. It is of a very pale yellow or white, and is sometimes called the white *Eucalyptus*. Its timber is curiously cross-grained, and it is hard, tough, and very strong and durable; from which known qualities it will no doubt attain a high rank a Lloyd's, and will be very extensively employed in ship-building, provided it can be obtained in sufficient quantities.

The morrell is a large fine tree, yielding timbers three feet in width, which has been used as treenails, and may probably become more generally esteemed.

The blue gum (*Eucalyptus globulus*) is an enormous tree, sometimes yielding planks 14 feet wide and more than 120 feet long. It is beginning to be used pretty freely in ship-building, and will, I believe, when better known in England, obtain at Lloyd's a much higher classification than is at present accorded to it.

But it is the jarrah (another of the *Eucalyptus* tribe) that forces itself so prominently and so urgently upon our attention. It has been very generally called mahogany, because one or two of its varieties bear a resemblance to that wood when polished; but when spoken of in relation to ship-building, I should advise its own name being adhered to.

It is very certain that there are many varieties of the jarrah, just as there are of the teak and other woods; and, by bearing this in mind, we can easily reconcile all the apparently conflicting statements in regard to its colour, disposition of fibre, hardness, density, and specific gravity.

Mr. Reveley, an engineer to the Government, speaking on this point, says:—"First, in colour, there is every variety of shade, from almost crimson to reddish brown, and pale brown inclining to white. In the second place, as to grain, there is almost every variety, from the perfectly straight fibre to every species of curl, including the zebra and satin specimens. The length of the stem of this tree, taking the average, may be 65 feet (many being much longer), without a branch or a knot in all that length, and very nearly equal in size all the way up; being veritable ornaments of nature. It is not attacked by insects of any kind, nor has it any tendency to dry-rot, and is scarcely affected in any way by damp or moisture." The truthfulness of this description will be clear to those who will inspect the specimens on the table this evening.

There are forests of this wood (almost wholly) in Western Australia, of more than four miles in depth, which are known to extend for a length of 150 miles, covering an area of more than 364,000 acres, containing timber sufficient to build 20,000 line-of-battle ships!

A knowledge of these facts is enough to stimulate enterprising capitalists, especially as this wood is known to be a beautiful and a valuable furniture-wood. Our merchant ships go out with emigrants and cargoes, but for a *return* cargo, they frequently wait and wait, and wait in vain; it would not be so if these vast forests could be opened up.

No wonder, then, that our enterprising merchants are turning their thoughts to this promising field of operations, and are seriously contemplating the construction of a short railroad (of eight to ten miles), to bring the timber to the shipping port. My own opinion is, that a company should be formed to carry out this important measure, and that Government should aid the undertaking by allotting to that company a sufficient number of selected "convicts" to work as labourers. It has often struck me that half the question as to the commercial success of the Great Eastern would be answered if she could always be sure of 10,000 to 15,000 tons of timber as freight on her passage from Australia.

THE PRESERVATION OF TIMBER-BUILT SHIPS.

But, after all, even the best of woods when made into a ship will exhibit decay much sooner than they should do. And why? In my humble opinion, it is because shipbuilders and shipowners will not adopt the simple but efficacious means which chemical science, confirmed by ample experience, offers them. Long years of practical experiment has shown that timber, however prone to dry-rot, or to wet-rot, may be effectually preserved from both by the use of certain metallic solutions or other suitable protective matters. One of the very best solutions for this purpose is that of sulphate of copper, which many years ago was patented by a Mr. Margary. Now this substance is sold, in quantities, at 4d. per lb. So that £100 would buy 6,000 lbs., and each lb. weight is sufficient for six to eight gallons of water. The process of saturation is a very simple one; the timber being placed in a closed iron vessel of great strength, is made to imbibe the solution by exhaustion and pressure, the operation occupying but a few minutes. Timber so treated is rendered perfectly exempt from all liability to dry-rot; whilst other injections, such as paraffine oil, the commonest and cheapest naphtha and oil, with a little resinous matter dissolved and mixed with oil, will effectually prevent the decay from wet-rot, &c. These are all such simple, well-known remedies, that almost everybody has heard of them; and yet it is positively true that neither the Admiralty nor the merchant shipowner has yet built one single ship in which these principles have been intelligently and thoroughly carried out. A reasoning and an undoubtedly shrewd man of business will have a fine ship built at a cost, perhaps, of £5,000; and yet he will not spend another £200 in rendering her timbers exempt from the attacks of insects and from rot. But if this indifference be astounding in the merchant shipowner, how shall we characterise such recklessness when exhibited in the construction of our men-of-war? Whilst on this subject I must call attention to some fine specimens (now on the table) of the gigantic pine, which has recently been imported from Vancouver Island, and to the following letter, which I received from the gentlemen who politely furnished me with those specimens. In this letter you will find that Messrs. Bilbe dwell upon the important circumstance of the gum or resin in these pines being "more uniformly diffused through the wood," thus tending to its impermeability and consequent preservation from decay. This is the chief object we should always strive to attain in treating timbers, with a view to their preservation:—

"Nelson Dock, Rotherhite, London, April 30, 1859.

"SIR,—We have been informed that a specimen or two of the wood recently imported by us for mast-making purposes would be acceptable to you; we therefore beg to forward you a slice cut off the side, and a cube of six inches cut out of the heart of one of the masts made by us. From the slice you will find some of the gum exuding, which appears to us to be of a different nature and more uniformly diffused through the wood than in any other variety of pine known to us. It seems to render the tree almost impervious to water, as in dressing the masts they feel quite dry while being planed up, although floating a few hours before. In its growth this pine is remarkable for its straightness and the absence of knots and defects, and for its very gradual taper. In fact the trees grow *masts*, maintaining by nature that taper which experience has proved the best for masts. While all the pieces imported by us are remarkable, some few are extraordinary; one tree is 129 feet long, and nearly 40 inches at one-third from its butt, without a blemish in it, and contains over 26 loads of timber. There was another, extraordinary in another way, its length being 118 feet 9 inches, whilst its diameter at the butt was only 15 inches and that at the top 6 inches. This was made into a flag-pole for Kew Gardens, but was unfortunately cut in two by a steamer, while it was entangled with Putney-bridge. . . . . This pine grows in the Oregon and Washington territories, and in Vancouver Island and British Columbia, where some of them acquire the height of 350 feet. It is, as you may suppose, a serious business to get them out of the woods to the water-side. Their importation into this country is a great boon to the Navy and Mercantile Marine. All those ship-owners who have had experience in the China trade, and in that to the north-west coast of America, can appreciate these mast-trees on account of their durability, which is scarcely inferior to that of teak. Those who have not that experience will, we hope, soon ascertain what is for their interest. Yellow pine, out of which masts of any size are usually made, is very perishable, its average durability being under five years, and when to the expense of renewing masts at short intervals, is added the expense of unrigging, taking out and in, and rigging again, besides the confusion and delay incurred therefrom, you will at once appreciate the value of these trees, if their average durability be only twice that of yellow pine. The writer has known them over ten years in a ship himself, and not a symptom of decay; and has been informed, among other instancesof durability, that in one of the dockyards a single bowsprit had worn out two frigates.

We, are, Sir, your obedient servants,

"THOS. BILBE AND CO."

"Leonard Wray, Esq."

Time will not permit me to enter more fully into this comprehensive subject of wood-preserving; but I must emphatically and respectfully warn our Admiralty to have every one of the sailing ships which are now being converted into screw steamers, as thoroughly saturated with the sulphate of copper solution as possible; especially in all those parts near the engines, boilers, and bunks. Let it be remembered that those ships were not intended for steamers when built, but that in opening them out for the purpose of lengthening them, opportunities will be afforded for using the preservative solution, which, as far as they are concerned, will never again occur. If this measure be not adopted I feel convinced that dry-rot will speedily destroy these ships, and many hundred thousands of pounds sterling will be lost to this country.

In conclusion, I beg leave very respectfully to suggest that the Council of this Society, in the interest of our naval and commercial marine, do address to her Majesty's Government a request that the Colonial Secretary shall order the several engineer officers residing in Honduras, Guiana, Assam, Tenasserim, Malacca, and Western Australia, to make a careful selection of the best and most durable timber woods of their respective localities, being not less than one or two tons of each timber, to season these lots in the most careful manner in the colony, and when fairly seasoned to send them home to the Government dockyards, where they may be examined and tested by a commission composed of duly-qualified men.

HALL AND WELL'S TELEGRAPH CABLES.

GENTLEMEN,—In your issue of the 6th inst. I observe in your description of Messrs. Hall and Well's mode of insulation of submarine telegraph conductors by india-rubber, that previously to coating with that material the conductor is covered with cotton. I also find in the specification of Messrs. H. and W.'s patent the following sentence:—"Our invention consists, first, in perfectly insulating the conducting wire or wires as follows: we commence by covering the conducting wire or wires with a spiral layer of cotton, and we prefer to use grey or unbleached cotton, as being the most pure." I do not profess to know enough about electricity to judge of the merits or demerits of the many new plans lately proposed. We poor shareholders have to take for granted, I fear, a great deal too much in a scientific way, and to pin our faith pretty much upon the sleeves of telegraphic engineers, patentees, and cable makers. I had always understood that cotton was a conductor; and it appears rather anomalous to me that the first step in what professes to be a perfect insulation should be the use of a conducting substance. As, however, great stress is laid upon the purity, perhaps cotton in this condition possesses superior virtues. I am glad to see attempts made to introduce india-rubber. We have had a considerable amount of expensive experience with gutta-percha; but before I would venture to trust myself again either in bands of gutta-percha or india-rubber, I should like to see my way, if possible, a little more clearly. Messrs. H. and W. would confer a great favour, I believe, upon many in the same category with myself, if they would in plain and simple language, and I do not care how briefly, explain how cotton assists in the insulation of their conductors, or what its office is. The removal of this difficulty, which at present I feel to be in the way of the full appreciation of the value of their contrivance, will be esteemed by, gentlemen, yours, &c., AN ENQUIRER.

THE CREMERIAN BOOT.—Mr. Cremer, of Regent-street, near the Polytechnic, has brought out an improved boot, in which a false sole is introduced *within* the boot itself, from half an inch to an inch in thickness, with which, by an ingenious elastic arrangement of the waist of the boot, the wearer feels no other alteration than that he is by so much raised above his fellows. The appearance of the foot in these boots is likewise very much improved, as the improvement has the effect of giving to the instep a much more elevated character, and causes the foot to look smaller.

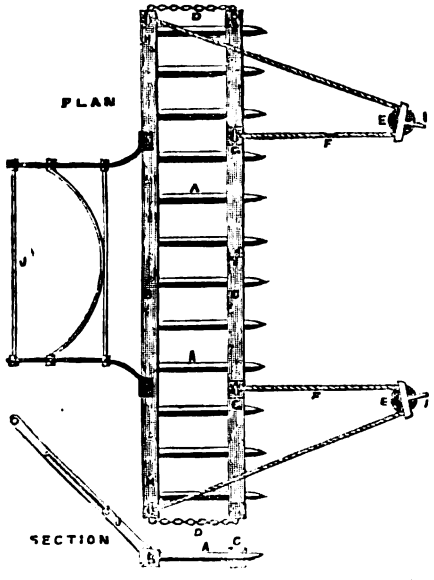
"DELTA'S" PATENT HORSE-RAKE.

THE teeth *A A* are fixed into the head *B* of the rake, and on the teeth is a slide *C* formed of two plain pieces of wood with distance blocks between, so as to allow it to slide freely upon the teeth *A A*. The slide *C* is attached at either end to the end *B* by a small chain *D D*, and over a pulley *E* (on each side of the rake) is passed a rope *F*, one end of which is fastened to an eye *G* in the slide *C* and the other end to the eye *H* in the head *B*. The horse is attached by trace chains to the loops *I* of the pulley blocks. *J* is the handle. The width of the rake is 9½ feet. When the horse draws the rake into the hay or stubble to be collected, the resistance of the head *B* and the slide *C* are equal; but as the hay accumulates the slide is pressed back until it is filled. To deliver the rakings it is only necessary to detain



the head of the rake by a slight pressure upon the handle, when the slide is drawn forward and the load discharged without altering the speed of the horse, the chains *D D* preventing the slide from going too far. Again the pressure upon the handle raises the teeth of the rake, causing it to pass over the winrow or discharged rakings, and falling upon the other side it again enters the spread hay.

If the teeth should be caught in the turf, or in any projecting piece of earth, the resistance is communicated to the head, which is thus detained, while the slide is drawn forward and frees them at once. It is necessary that the rope should run freely over the pullies.

Mr. R. Law, of Shettleston, by Glasgow, is making a large number of these very simple and efficient rakes for the coming harvest.

NOTICES.

The MECHANICS' MAGAZINE will be sent free by post to all subscribers of £1 1s. 8d., annually, *payable in advance*. Post Office Orders to be made payable to R. A. Brooman, at the Post Office, Fleet Street, London, E.C.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 5d. per line for any number of insertions less than 13; for 13 insertions, 4d. per line; and or 52 insertions, 3d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

THE demand for Mr. E. J. REED'S paper—

ON THE MODIFICATIONS WHICH THE SHIPS OF THE ROYAL NAVY HAVE UNDERGONE DURING THE PRESENT CENTURY, IN RESPECT OF DIMENSIONS, FORM, MEANS OF PROPULSION, AND POWER OF ATTACK AND DEFENCE,"

has been so great that the Journal of the Society of Arts, the MECHANICS' MAGAZINE, and all other Scientific Journals in which it appeared in December last, are now out of print. The demand still continuing, it has been deemed desirable to reprint it in a separate form. An 8vo. edition of it, in large type, and on fine paper, has, therefore, been prepared, and may now be had at the Office of this Magazine, price 1s.

Our Weekly Gossip.

A NUMBER of a curious publication called *The Balloon; or, Aerostatic Magazine*, has this week been sent to us. It appears to be under the management of Mr. Henry Coxwell, of Tottenham, and to have been first projected by him in the year 1845. It does not appear, so far as we can ascertain, that it is issued at regular intervals. It is proposed that another number shall be published in the autumn, with the view of taking a retrospective glance at the aeronautic exploits of the season. The number before us contains, first, a sketch of the rise and progress of the drag and sail plan for directing balloons. This is followed by an article upon the question, "Is aerostation progressing?" In this Mr. Coxwell tells us that after twenty years devoted study of aerial navigation, he finds no reason why this question should be replied to in a tone of despondency, but at the same time he has no hesitation in affirming "that the advantages likely to accrue from unrestrained intercourse through the atmosphere are so great and exalting, that the world is not yet prepared for such a consummation, nor will it be until despots shall have been hurled aside; for the air-borne car is the emblem of liberty, peace, and good-will; a messenger that will wing her way probably when humanity shall have been further ameliorated, and the passion for war gives way to lasting repose. . . . . Ballooning as an art is, I am convinced, steadily advancing; and although the uninitiated may not observe much progress, because the machine does not strikingly deviate from the wind, yet the various appurtenances gradually undergo improvement, and in a short time I have no doubt that balloons, like the old men of war, will be cast aside for new models; and then, just as the application of steam requires a reconstruction of our war vessels, so will some new power demand a similar alteration for vessels in the air; so that if balloons cannot be managed, elongated aerostats may; and the difficulties which appear insurmountable at the beginning of the nineteenth century may be at last dispelled, and the great high-road to all the nations of the earth (the atmosphere) may be travelled triumphantly." The next paper is upon war balloons for reconnoitring. In this Mr. Coxwell says: "I assert with no small degree of conviction, if not of assurance, that by no other medium could so much information be acquired as from the car of a balloon, elevated kite fashion, and subject to control by ropes regulating its altitude. The idea owes its origin to French ingenuity, and a Frenchman acquitted himself valiantly at the battle of Fleurus. Guyton Morveau proposed balloons as a means of observation for the French armies, and they were repeatedly used with advantage at places too numerous to particularize. But as the aeronautic art was not, mechanically speaking, in anything like the state of advancement it is now, I am of opinion that under expert management balloons may be made the vehicles, not only for acquiring information instantaneously, but also, on some occasions, for destructive and incendiary objects. This may be pronounced an abuse of such a philosophical instrument, but the reply of a matter-of-fact man would be the old adage, 'All is fair in war.'" Further on in the same paper the writer suggests that as we are about to cover the channel with our wooden walls, we should proceed further, "and station on the most approachable parts of our coasts a few aerial observatories, in order not only to command a view of our fleet, but also of portions of foreign soil within telescopic range of England. Half-a-dozen balloons judiciously located would afford the means of observation, and the aerostatic telegraph would be ready to facilitate the movements of the coast-guard, and to render other service of importance." The exploration of Australia by balloons, is the next subject treated of; and then we have in succession "Meteorological hints to Aeronauts," "Reporting in Cloud-land," &c. We have thus glanced at this curious publication because many of our readers are interested in the subject of which it treats. The work bears no publishers' name or price, but we dare say it can be obtained for a few postage stamps from Mr. Coxwell himself at Tottenham.

An old correspondent sends the following, under date of May 9:—"There appears to be some difference of opinion between electricians and telegraphic engineers with respect to the utility of having a second wire for the return current in so long a cable as the Atlantic, and those gentlemen who are opposed to the idea seem not exactly to comprehend the real object and necessity for it. It has been surmised that the object in view was to get rid of what is certainly a great difficulty, namely, the effects of induction in the principal cable; but, in reality, no such object was ever calculated, at least by me, and I believe I was the first person who suggested the second wire; a few words, therefore, on the subject may not be thought unnecessary. There appears in your last publication an interesting paper, copied from a communication made to the Society of Arts lately, and I have taken the liberty of copying a passage therein for the purpose of making some observations on it. The writer says, 'That it is a well-established fact that when a telegraphic circuit is composed of a loop of wire, it will oppose the same resistance to the electricity as a circuit of double the length when the earth is made use of in the place of a return wire, and he says this proves the earth offers no apparent resistance, and he continues, if this be the case, can it make any difference whether the battery pole be carried to the ends of the wire itself, or through the medium of any perfect conductor, which the earth has been proved to be.' In the first place, I have to observe all the statements in this paragraph require to be proved; they contain the substance of the matter in dispute, and if they were true, it would be a most important discovery, and would go the length to upset and contradict some of the elementary and most important principles in electricity. In my last communication to you, published 11th December, 1858, No. 1844, I described some experiments which went to prove that in every circuit traversed by the electric current, that portion of the circuit composed of the most imperfect conducting material, governed and controls the quantity of electricity put in motion, I shall not again, therefore, trouble you with a repetition of these experiments, but I will describe an additional one taken from the late Sir Humphrey Davy's work, Davy's 'Chemical Philosophy,' page 151, and apply the experiment in such a way as to put the matter beyond dispute, and prove that there exists more difficulties in the way of a perfect Atlantic cable than that caused by the induced electricity in the gutta-percha covering of the wire. Davy, in describing Mr. Children's powerful battery, which consisted of twenty double plates four feet by two feet—this great battery, he says, when in full action had no more effect on water or on the human body than a battery containing an equal number of small plates, but when the circuit was made through metallic wires, the phenomena were of the most brilliant kind; a platina wire of one-thirtieth of an inch in thickness, and eighteen inches long, placed on the circuit between copper bars, instantly became red hot, then white hot, the brilliancy of the light was soon insupportable to the eye, and in a few seconds the metal fell fused into globules. The other metals were easily fused or dispersed in vapour by this power, points of charcoal ignited produced a light so vivid that even the sunbeams compared with it appeared feeble. Now, let us in imagination take this battery to the telegraphic station house at Valentia, and, in the first instance, perform all those brilliant experiments here described; we will afterwards try the shock on ourselves; we need not fear any danger as we have Sir Humphrey Davy's word that it is not dangerous, but we will note down in our book this important fact, the enormous disproportion between the large quantity of electricity required to pass through the circuit when eighteen inches of platina wire was used, with the very small quantity which circulated when our hands joined the poles of the battery in taking the shock. Let us now attach an insulated cable to one end of the battery—I mean a properly constructed cable—and let it terminate at the station-house at St. John's, Newfoundland, and let a strong copper wire be attached to the other pole of the same battery and be continued likewise to the same station. We will now proceed ourselves across the Atlantic and visit the station. I should have mentioned that it is essential that this latter wire should not be insulated with gutta percha; we have quite enough of that mischievous material in one of the wires, and we don't want a repetition of the difficulties attending it when necessitated to make use of it. Being now at St. John's station, and repeating the experiments with the ends of the two wires which we have now to experiment with, it is not very likely that if we connect the two wires with a platina wire eighteen inches long, as we did at Valentia, that the same brilliant results would follow. The electricity has by this time travelled 1,600 miles; the most we can expect from it would be that by attaching the wires to the ends of an ordinary indicator that we would get some deflection of the needle; indeed, we do not require more for telegraphic purposes. But if the powerful instrument at Valentia, and with a metallic circuit throughout, is not able to deliver more electricity with such a length of cable than what will deflect the needle of a galvanometer, and taking into consideration the note we took and entered in our note book at Valentia, how can it, I say, be expected that if we make the connection with these two wires and

Digitized by Google

the indication by passing the electricity through the human body—how can it, I say, be expected that with such an arrangement the needle could be affected? much more, how could it be expected that if the second wire had been altogether removed and the circuit be completed by 1,600 miles of moist earth and salt-water, that it would be more successful. The idea seems preposterous? Having several wires in the principal insulated cable is very good, but in the present cable, in consequence of its construction, was productive of mischief. The gutta-percha is pressed closely round and in close connection with each wire, whereas the wires should touch each other and be bound firmly round together with linen, or hemp, or some other imperfect conducting substance before the gutta-percha is applied; and the suggestion of Mr. Hearder is a great improvement,—layers of gutta-percha with an intermediate covering of linen again.—I am, Sir, P. M. May 9th, 1859."

Patents for Inventions.

PROVISIONAL PROTECTIONS.

Dated April 1, 1859.

818. W. E. Newton, of Chancery-lane. Improvements in cricket bats. A communication from M. Doherty.

Dated April 8, 1859.

881. W. E. Newton, of Chancery-lane. Improvements in telegraphing and in telegraphic apparatus. A communication from A. Wilson.

Dated April 11, 1859.

902. W. Boaler, of Manchester, Merchant. Certain improvements in the manufacture of soap. Partly a communication from A. Hay.

Dated April 18, 1859.

976. W. E. Gedge, of Wellington-street, Strand. An improved safety apparatus for clearing off condensed steam from steam-engines. A communication from A. Morel.

Dated April 19, 1859.

984. W. Gosling, Architect, of Woolwich. Improving rifle cannon and projectiles.

Dated April 20, 1859.

998. J. Apperly, Cloth Manufacturer, and W. Clissold, Engineer, of Dudbridge. Improved apparatus for oiling wool.

Dated April 26, 1859.

1044. W. Mackenzie, Publisher, of Glasgow. An improved method of printing impressions upon an enlarged or reduced scale, either from engraved plates, electrotypes, blocks, drawings, or other surfaces.

Dated April 27, 1859.

1056. J. and W. Stuart, of Musselburgh, Mid-Lothian, Manufacturers. Improvements in machinery or apparatus for manufacturing nets for fishing, and for other purposes.

Dated April 28, 1859.

1065. C. Randolph and J. Elder, of Glasgow, Engineers. Improvements in steam-engines and boilers.

1067. R. Harrington, Watch Maker, of Camberwell. Improvements in umbrellas and parasols.

1069. N. J. Holmes, Gentleman, of Glasgow. Improvements in electric telegraphs, and apparatus connected therewith.

1070. E. Lardenois, of Brussels, Merchant. Improvements in the manufacture of pulp for paper, pasteboard, and other like articles. A communication from B. F. Brunel.

1071. T. Clarke, of Hackney, Engineer. Improvements in sheaves or pulleys for paying out and hauling in ropes, chains, and cables, for communicating motion to machinery, and for other useful purposes.

1073. W. A. Tompson, of Cecil-street, Strand, and W. Green, of Thames Ditton, Surgeon. Improvements in apparatus for applying liquids to the throat and air passages, for medical purposes.

Dated April 29, 1859.

1076. W. Corbett and W. Carmont, of Clayton, near Manchester, Iron and Steel Manufacturers. Certain improvements in the construction and arrangement of furnaces employed in the manufacture of iron and steel, and for other similar purposes.

1077. J. W. Welch, of Manchester, Warp Sizer. Improvements in sizing or dressing yarns or threads for weaving.

1079. E. A. Portens, of Warwick-sq., Engraver, and W. H. Burke, of Cannon-st. West, Manufacturer. Improvements in printing and other presses.

1081. T. Smith, of Bredfield, Suffolk. Improvements in cultivating implements.

Dated April 30, 1859.

1083. J. Tousaint, of Welbeck-street. A new process of modelling and moulding for galvano-plastic.

1084. J. Darlington, of Cannon-st., Mining Engineer. Improvements in zinc retort furnaces.

1085. E. Francis, of Wrexham, Grocer. Improved apparatus applicable to the treatment of tea and other useful purposes.

1086. J. Morison, sen., and J. Morison, jun., of Paisley, Machine Makers. Improvements in looms and in apparatus connected therewith.

1087. W. Clark, of Chancery-lane. Improvements in ventilating or supplying air to diving bells and divers, and in holding communication therewith from above. A communication from F. A. Laurent.

1089. J. Bull, of Manchester. Improvements in apparatus used for securing bales of cotton and other substances.

1090. C. H. G. Williams, of Regent-sq. Improvements in the manufacture of colouring matters, and in applying the same for dyeing and printing fabrics and materials.

1091. J. Souquière, of Paris, Civil Engineer. A new or improved process for distilling coal.

Dated May 2, 1859.

1092. T. H. Arrowsmith, of Bolton, Cotton Spinner. Improvements in carding engines.

1093. A. Jumelais, of Paris. An apparatus yielding illimited power, so called "French movement."

1094. J. Ferguson, of Kilmarnock, Tinsmith, and J. Mc Gaveny, of Glasgow, Yarn Dresser. Improvements in fasteners for shutters, and for similar uses.

1095. W. Baylis, Fencing Manufacturer, of Wolverhampton. Improvements in the manufacture of iron hurdles and fencing.

1096. R. A. Brooman, of 166 Fleet-st., London, Patent Agent. Improvements in, and in connection with, electro-magnetic engines. A communication from A. P. M. Darlu, of Paris.

1097. J. Basford, of Oundle. An improvement in the apparatus used when expressing clay or brick earth through dies.

1098. J. Childs, of Putney. Improvements in the manufacture of night-light cases.

1099. W. Gossage, of Widnes, Chemist. Improvements in the manufacture and useful application of certain alkaline silicates, and in the production of liquor silicis, or liquid flint.

1100. D. Moore, of Brooklyn. Improvements in machinery for rubbing or dressing types.

1101. W. Gossage, of Widnes, Chemist. Improvements in the manufacture of caustic soda and carbonate of soda, from certain alkaline liquors and salts.

1102. C. Nuttall, of Rochdale, Machinist. Improvements in machinery or apparatus for grinding wire cards.

1103. F. W. Emerson, of Fenchurch-st. Improvements in treating ores to obtain a new metallic substance and its salts, and in the application of such matters, and also certain products of tungsten in dyeing, printing, and painting.

Dated May 3, 1859.

1104. A. G. Franklin, of South-st., Finsbury, Merchant. Improvements in the manufacture of crayons. A communication from G. W. Sussner.

1105. W. Johnson, of Lincoln's-inn-fields. Improvements in the manufacture or production of mineral oil and grease. A communication from F. Schütze.

1107. W. Clark, of Chancery-lane. Improvements in obtaining or extracting quinine and the principal organic alkalies. A communication from L. de Sourdeval.

1109. W. Sellers, of Philadelphia, Engineer. Improved machinery for making screw bolts and nuts.

1112. H. Chapman, of Appleby. An improved military camp cooking apparatus.

1113. H. Chapman, of Appleby. Improvements in the construction of kettles.

1114. E. W. Scale, of Merthyr Tydfil, Gentleman. Improvements in railway signals.

1115. R. Mushet, of Coleford, Metallurgist. An improvement in the manufacture of cast steel.

Dated May 4, 1859.

1116. W. H. Kingston, of Bandon, Cork. Improved means of communication between the passengers and guards, and guards and engine drivers, of railway trains.

1117. C. F. Vasserot, of Essex-st., Strand. An improved form of tuyere for blast furnaces. A communication from F. C. Bierlein.

1118. J. Adolphus, of Serle-st. An improvement in locks, bolts, and latches.

1119. W. E. Newton, of Chancery-lane. Improvements in steam-boilers. A communication from S. Pierce.

1120. J. G. Willans, of Belfast. Improvements in utilizing bog stuff or peat, when applied for treating metals and certain mineral and alkaline substances.

1121. J. C. Wilson, of Manchester. Improvements in machinery for cleaning cotton.

Dated May 5, 1859.

1122. H. Turner, of Mile-end, Engineer. Improvements in steam-engines and apparatus connected therewith.

1123. J. F. Allender, of Brierley Hill, Stafford, Manager, and D. Rowley, of Brierley Hill, Iron Roller. Improvements in shears for cutting boiler plates and sheets, and for other like purposes.

1124. J. Scholfield, of Milnrow, near Rochdale, Cotton Spinner, and W. Cudworth, of the same place, Manager. Certain improvements in machinery or apparatus for spinning cotton and other fibrous materials.

1125. H. Chapman, of Appleby. Improved means or appliances for protecting ships against injury from shots, shells, or other warlike projectiles.

1126. H. Chapman, of Appleby. Improvements in the construction of fortifications.

1127. W. F. Batho and E. M. Bauer, of Salford, Engineers. Improvements in drills for recessing, cutting slots, keyways, and cotter holes.

1129. W. Clark, of Chancery-lane. Improvements in seed depositors or drills. A communication from L. A. Pruneau.

1130. A. Knox, of Kingsland, Engineer. Improvements in gas regulators.

1131. H. Reynolds, of Denmark-hill, Gentleman. Improvements in refining sugar and other saccharine substances.

1132. R. A. Brooman, of 166 Fleet-st., London, Patent Agent. Improvements in cannon and other fire-arms, and in projectiles, wads, and cartridges to be used therewith. A communication from J. W. Cochran.

1133. H. Fletcher, of Southampton-buildings. A machine for scutching and carding tow, oakum, or waste cordage. A communication from F. Maigron.

1134. W. E. Newton, of Chancery-lane. An improved steam-gauge. A communication from A. E. Dupas.

1135. W. E. Newton, of Chancery-lane. Certain improvements in fish-hooks. A communication from T. F. Weil.

1136. J. H. Johnson, of Lincoln's-inn-fields. Improvements in piano-fortes. A communication from G. Vogt.

Dated May 6, 1859.

1137. W. Kellingley, of New Cross, Carriage Builder. Improvements in the mode of lubricating the journals of the axles of locomotive engines, of carriages and machinery.

1138. F. Angerstein, of Kennington, Esq., Robert Clegg, of Islington, Gentleman, and G. Thorrington, of Egham, Lighterman. Improvements in apparatus for obtaining motive power.

1139. F. W. Hart, of Horncastle, Lincoln, Photographer. Improvements in photographic apparatus.

1140. S. Wright, of Sudbury, Suffolk, Gas Engineer. An improved gas governor or regulator.

1141. J. Dixon, jun., of Blackburn, Paper Stainer. Improvements in machinery or apparatus for staining paper.

1143. W. S. Booth, of Birmingham, Undertaker. A new or improved washing machine.

1144. J. Frearson, of Birmingham, Mechanical Engineer. New or improved fastenings for wearing apparel, and for such other purposes as the same are or may be applicable to.

1145. G. T. Bousfield, of Brixton. Improvements in apparatus for grinding grain and other substances. A communication from P. E. Brisson.

Dated May 7, 1859.

1146. J. Combe, of Paris, Gentleman. An improved plantoforme or apparatus for measuring the hoofs of horses for the purpose of forming their shoes.

1147. J. Bray and J. W. Harrison, of Staley Bridge. Improvements in machinery or apparatus for spinning fibrous materials.

1148. A. C. Bamlett, of Middleton Tyas, York, Farmer. Improvements in reaping machines, part of which improvements is applicable to other agricultural implements.

1149. M. Henry, of Fleet-st. Improvements in the manufacture and construction of locks and fastenings. A communication from J. N. Rebour.

1150. R. Mushet, of Coleford, Metallurgist. Improvements in puddling iron and steel.

1151. R. Mushet, of Coleford, Metallurgist. Improvements in the manufacture of iron.

1152. C. Frost, of St. George's-in-the-East. Improvements in the construction of electric telegraph cables.

1153. R. Pearsall, of Smethwick, Stafford, Glass Blower. Improvements in the manufacture of glass shades.

1154. W. E. Gedge, of Wellington-st., Strand. Improvements in the manufacture of steel. A communication from C. J. Perinel.

1155. R. D. Kay, of Accrington, Manufacturer. Improvements in the preparation of certain colouring matters. A communication from Dollfus Mieg and Co.

1156. W. Jeffery, of Gloucester. Rendering more convenient out-door manipulations in photography by means of an improved portable photographic tent and tent camera.

Dated May 9, 1859.

1157. J. Ramsbottom, of Crawshaw Booth, Lancaster, Machine Printer. Certain improvements in machinery for printing fabrics.

1159. C. A. H. Marcoux, of Montmartre, near Paris. A new impelling mover by the pressure of water.

1163. A. Morton, of Kilmarnock. Improvements in means or apparatus employed in the weaving of figured fabrics.

1165. T. Green, jun., of Old Broad-st. Improvements in apparatus applicable to steam boilers, to obtain greater security against explosion.

Dated May 10, 1859.

1167. W. F. Nuthall, Major, of Kilburn. Improvements in ordnance and fire-arms, and in projectiles to be used therewith.

1169. W. Wilkinson and C. Whitley, of Manchester. Improvements in buttons and fastenings for garments, harness, and other similar purposes, and in the method of securing the same.

1171. J. Norman, of Glasgow, Engineer. Improvements in furnaces.

1173. G. Bell, of Wandsworth, Manufacturer. Improvements in matches or fusees.

1175. W. Keiller, of Perth. Improvements in cartridges for guns or small fire-arms.

1177. J. Absterdam, of New York, Mechanical Engineer. Improvements in impregnating illuminating gas with hydro-carbon vapour.

Dated May 11, 1859.

1179. A. Manbré, of Rathbone-place, Oxford-st., Brewer. The manufacture of a colouring matter for colouring spirits, beers, vinegar, and other liquids, from sugar produced from rice, maize, carrots, maple, amanas, pompions, chestnuts, mangel-wurtzell, sorgho, turnips, and Jerusalem artichokes.

1181. J. Luis, of Welbeck-st. An improved burling and napping machine. A communication from J. B. Duval.

1183. M. Henry, of Fleet-st. A mode of protecting the mariner's compass against local attraction. A communication from S. C. Bishop.

1185. W. Spence, of Chancery-lane. Improvements in knapsacks and other military equipments. A communication from J. Rider.

1187. J. Leadbetter, of Leeds, Brazier, and J. Rhodes, of Armley, near Leeds, Water-rate Collector. Improvements in pumps.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(From the London Gazette, May 24, 1859.)

92. W. Oliver. Boats.
106. W. Bennetts. Raising or lowering skips, &c.
110. J. Picksley and R. Sims. Mowing machines.

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

STEAM ENGINES, &c. *None.*
BOILERS AND THEIR FURNACES, 2296, 2332, 2347, 2350.
ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 2335.
SHIPS AND BOATS, including their fittings, 2298, 2315, 2337.
CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 2308.
FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, 2318.
FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 2297, 2299, 2300, 2331, 2344, 2348, 2355.
BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c., 2338.
LIGHTING, HEATING, AND VENTILATING, 2312, 2325, 2332, 2345.
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 2302, 2343, 2349, 2352, 2360.
METALS, including apparatus for their manufacture, 2361.
CHEMISTRY AND PHOTOGRAPHY, 2295, 2307, 2336, 2342.
ELECTRICAL APPARATUS, 2317, 2321, 2322, 2326.
WARFARE, 2310, 2329, 2330, 2353.
LETTER PRESS PRINTING &c, 2351.
MISCELLANEOUS, 2293, 2294, 2301, 2303, 2304, 2305, 2306, 2309, 2311, 2313, 2316, 2319, 2320, 2323, 2324, 2327, 2333, 2334, 2339, 2340, 2341, 2346, 2354, 2356, 2357, 2358, 2359.

2293. S. PERKES. *Improvements in machinery for extracting oil from the cocoa nut and other vegetable matters.* Dated October 14, 1858.

Here the coprah is reduced into a pulp by a rotating rasp made up of circular saws, and such pulp is continuously fed on to an endless table or chain, which is reticulate, or made with suitable passages through for the passage of the oil. This endless chain or table is supported by several rollers on its under side, and the pulp of coprah is fed on to the same at the upper end of the machine, there being suitable mats or fabrics of cocoa-nut fibre, &c., on the under and upper surface of the vegetable matters so fed on to the endless table, which is arranged by preference in the form of an inclined plane from the upper to the lower end of the machine. The part of the endless chain or table for the time out of action passes under the supporting rollers, and there are trays under the supporting rollers to receive and conduct off the oil to suitable receivers. The endless chain or table in its movement over the supporting rollers passes under a number of pressing rollers, there being one such roller over each supporting roller. The first or uppermost pressing roller is at the greatest distance above the table or endless chain, so as to offer comparatively little pressure to the vegetable matters on the table, and the rollers in succession are set nearer and nearer to the endless table or chain, by which as the table or chain progresses the matters thereon become subjected to greater and greater pressure. The rollers are made hollow so as to be heated by any suitable hot fluid or otherwise, and in some cases the pressing surfaces of the rollers are of glass. In order to separate the fluid oils from foreign matters centrifugal machines are employed. *Patent completed.*

2294. H. MARTIN. *Improvements in separating starch from gluten, in apparatus used therein, and also in preparing cement from gluten.* Dated October 14, 1858.

Here a rectangular trough is used, having wire gauze let in at the ends and middle. In this trough a reciprocating frame is used carrying rollers, by preference four. The dough which is to have the starch separated from the gluten is placed between the two end pairs of rollers, the frame is made to reciprocate, and a constant flow of water is allowed to flow on the dough, which will wash out the starch from the gluten, the wash water continually flowing through the wire gauze into a suitable vessel to settle, and there to be treated in the ordinary manner of manufacturing starch. After the dough has been subjected for a time to the action of the frame of rollers the dough—now for the most part gluten— is placed between the ends of the frame and the ends of the trough, by which the dough or gluten is continually beaten by the ends of the frame whilst still subject to a constant flow of water. In order to convert gluten into cement it is combined with stale beer or fermented liquor and oil. *Patent completed.*

2295. G. BAXTER. *Improvements in colouring photographic pictures.* Dated October 14, 1858.

This consists in combining with photographic pictures the processes of intaglio plate and surface printing, and also the processes of lithographic and zincographic printing, as a means of colouring such photographic pictures. *Patent completed.*

2296. T. ARCHER, jun. *Improvements in apparatus for preventing explosions of steam boilers.* Dated Oct. 14, 1858.

Here the supply valve is enclosed in a case having an opening at the top, through which the rod of the safety-valve passes, and by which steam passes from the boiler when the safety-valve is somewhat raised. On the rod of the safety-valve there is another valve, which, when the safety-valve is raised beyond a certain point, closes the opening in the top of the case, and causes the steam to pass through a pipe which leads from the case to the interior of the furnace of the boiler, and so damps the fire and reduces the pressure on the boiler. Steam is also caused to pass on to the fuel in the furnace when the water in the boiler gets too low. This is accomplished by a float in the boiler having a rod attached to it, which passes through a stuffing-box in the top of the boiler. This rod also passes through a hole in a prolongation of the weighted roller, which keeps down the safety valve, and on the end of the rod there is an enlargement which cannot pass through the hole in the lever. Thus, when the water in the boiler gets too low, the weight of the float depresses the arm of the lever through which the rod passes, lifts the arm of the lever which keeps down the safety-valve, and allows the steam to pass on to the fuel in the furnace. *Patent completed.*

2297. S. DIGGLE. *Improvements in looms for weaving.* Dated October 14, 1858.

This relates, 1, to mechanism for moving the boxes of looms in which two or more shuttles are employed; but neither this nor the remaining portions of the invention are described apart from the drawings. *Patent completed.*

2298. W. E. NEWTON. *An improved construction of cabin or state room for steam-boats and other vessels.* (A communication.) Dated October 14, 1858.

The object here is the construction of air-tight cabins or state rooms, for steam-boats, &c., which are so arranged and adapted to the vessels that they shall, in the event of the hull of the boat or vessel sinking, be capable of automatically detaching themselves therefrom, and also of floating on the surface of the water, and under the control of the occupants. *Patent completed.*

2299. J. LOMAS. *Improvements in the production of ornamental fabrics for ladies' dresses.* Dated Oct. 14, 1858.

This applies to cotton, woollen, silk, or other piece goods upon which patterns are produced by processes of printing, weaving, or by other means, and consists in forming another pattern thereon by embossing, and so that the said embossed parts, when the piece is made up, may follow a leading outline of the dress. *Patent abandoned.*

2300. R. R. JACKSON. *Certain improvements in machinery or apparatus for sizeing yarn.* Dated Oct. 15, 1858.

This consists in the use of a ball or other float tap or valve for regulating the supply of size to sizeing machines, in which tap the escape of the liquid through the tap is prevented by a piece of india rubber, &c., which is pressed by the float against the seating of the tap, or is opened, and leaves the same to supply the cistern as the float rises or falls in the sizeing liquid. The float may be placed in a separate cistern, so as to feed a number of machines, or in a small cistern attached to the trough of each machine. *Patent abandoned.*

2301. W. BACON. *Improvements in the mode of constructing valves, valve cocks, gates, and stop cocks, which may be used in steam engineering, and for other purposes.* (A communication.) Dated October 15, 1858.

This consists in so constructing a peculiar form of oscillating valve that when it is in position to leave its ports uncovered, there will be a passage or passages from the induction port or ports in the valve chamber to the eduction port or ports in the same through the valve and the valve spindle, thereby causing less friction to the steam, water, air, gas, &c., passing through it, and thus obviating loss of pressure or head. It also consists in so constructing the valve that when it is in position to cover its parts, it will prevent the flow of a fluid from the valve chamber through either of the ports alternately, so long as the spindle remains unturned; and also in so constructing it that the springs which hold the separate parts of the valve against their seats shall not act on the spindle to force it from its centre of motion. *Patent completed.*

2302. G. DAVIES. *Improvements in the manufacture of gloves, and in the apparatus employed therein.* (A communication.) Dated October 15, 1858.

Here the cutter is formed with moveable pieces or blades, and is suitable for cutting from one to several dozens of gloves of four different sizes at one blow. The number of seams in the fingers of each glove is reduced to four. *Patent completed.*

2303. T. MOORE. *Improvements in refrigerators.* Dated October 15, 1858.

Here a polygonal vessel is formed of cast-iron, with fretted or interwoven channels, ascending with a slight gradient from the base or sides of the vessel to the centre. These channels commence at one angle of the polygon and run parallel to the sides, that in connection with the last side being the width of the first channel shorter than the others. All are returned at the same angle as the sides, and continued throughout, diminishing in regular succession. Partitions of galvanised iron separate the channels, which are formed of such depths as to contain a series of pipes. These pipes are placed between the partitions, they are continuous, and so connected at the angles that by removing a cap with a screw or telescope joint, one end of each pipe may be opened, the cap or accessible end throughout having the same relative position, that is, each

Digitized by Google

being in the end of the pipe forming, when the vessel is other than square, a re-entrant angle with the pipe next in ascending progression. The pipes are connected with the inlet for the work at the bottom, and with the outlet at the top, and the whole bound together in position, so that they may be raised out of the containing vessel at pleasure. *Patent completed.*

2304. S. T. CLARKE. *A mode of crossing bankers' cheques and drafts.* Dated October 15, 1858.

Here the parallel lines, with the banker's name, or simply the words "and Co." appear in perforations. The apparatus consists of a tool fitted with a series of small punches fitted into any convenient form of press. *Patent abandoned.*

2305. J. WAINWRIGHT. *Improvements in respirators.* Dated October 15, 1858.

This consists, 1, in employing two valves for allowing the inhalation and exhalation to be conducted through separate media. 2, in employing a series of metal plates—by preference three in number—in place of wire gauze. *Patent abandoned.*

2306. G. T. BOUSFIELD. *Improvements in machinery for cutting the threads of wood screws.* (A communication.) Dated October 15, 1858.

This consists in producing wood screws tapering with a slope at the point, and tapering with a slope, also, where the core vanishes into the stem of the screw, so that the projections of the convolutions of the tapering portions shall slope towards the point, and be inclined to those of the core at the body of the screw between the tapering portions thereof. *Patent completed.*

2307. G. F. WILSON. *Improvements in preparing compounds containing sulphur for preventing and destroying blight, mildew, and insects.* Dated October 15, 1858.

This consists in preparing compounds of sulphur and soap, by combining sulphur in a state of solution with soap. *Patent completed.*

2308. L. MARCUS. *An improved reaping machine.* Dated October 16, 1858.

This consists chiefly in the use of a gathering rack actuated by the same movement as that of the other organs. This rack takes on the table, the cut grain, and by a travelling motion brings it back on the table, throwing it aside in small heaps for bundling. The cutter works in a space larger than that in which the other pieces of the machine are actuated by the action of the large wheel, which is caused to pass outside of the grain to be cut, that is to say, in the space which serves also for the passage of the horses. *Patent completed.*

2309. F. J. COULON and S. G. GIRAUD. *Improvements in the process of ornamenting skin and leather.* Dated October 16, 1858.

This consists mainly in the application of a calender disposed and combined in a peculiar manner. *Patent completed.*

2310. T. W. G. TREEBY. *An improvement in breech-loading fire-arms and cannon.* Dated October 16, 1858.

This invention is not described apart from the drawings. *Patent completed.*

2311. H. FRANCIS. *Machinery for making the springs of surgical trusses.* Dated October 16, 1858.

This consists in passing a strip of hot steel between rollers suitably arranged, instead of forging it. *Patent abandoned.*

2312. J. P. GILLARD. *Improvements in generating hydrogen, and in the means of and apparatus for applying the same to lighting and heating purposes.* Dated October 16, 1858.

In carrying out this invention (which relates to a previous patent, dated 22nd November, 1849) steam is obtained from a boiler heated by the last heat of the furnace, and that by introducing this steam at once into the retorts—the head of these latter should not be lowered too much—the patentee causes the steam, previously to entering the retorts, to pass through tubes situated in the interior of the piers or buttresses of the brickwork of the furnace, by which the steam will become sufficiently superheated, so as not to cause the charcoal to coal too quickly. The steam is introduced into the retorts by tubes having perforated roses, and situated in the interior of the retorts. These tubes extend over the entire length of the layer of charcoal. The steam is so distributed over the decomposing material that an equal degree of heat is kept up on the entire surface of the decomposing material, whereby an equal decomposition of the steam and evolving of hydrogen will be secured, and the generating of carbonic oxide in great measure prevented. *Patent completed.*

2313. J. HICK, W. HARGREAVES, and R. HARWOOD. *Improvements in governors or regulators for prime movers.* Dated October 16, 1858.

This relates to apparatus for regulating the supply of water to water-wheels, and consists in connecting the slow shuttle or valve, the position of which is to be adjusted for regulating the speed of the water wheel, &c., with a piston moveable in a cylinder. *Patent completed.*

2314. P. JENSEN. *An improved apparatus for governing or regulating the speed of marine engines.* Dated October 16, 1858.

Here the inventors employ a cylinder placed in communication with the water at one end, whilst the other end thereof is closed. It is fitted with a moveable piston, and the latter is connected with the throttle or other valve regulating the admission of the steam to the cylinders of the engine. The more deeply the stern of the ship becomes immersed the more the pressure of the water upon the piston in the regulating cylinder increases, the greater is the force wherewith the piston is thrust towards the closed end of the cylinder, and the more the air between the piston and cylinder cover becomes depressed, and *vice versâ*. *Patent abandoned.*

2315. A. ROBERTSON. *Improvements in applying starch and similar matters.* Dated October 16, 1858.

This consists, 1, in causing the fabric, &c., to be passed in contact with a roller or drum having a film of the starch or similar matter on its surface and moving in the same direction as the fabric, &c., but at a slower rate; 2, in rubbing the starch, &c., into the fabric by a second roller or drum, and moving in a direction opposite to that of the fabric, but not supplied with starch, &c. *Patent abandoned.*

2316. A. DUNN. *An improvement in preparing marking compounds to be used on linen and other fabrics.* Dated October 16, 1858.

This consists in making up materials, such as the compounds of silver, &c., and other materials used in the preparation of marking inks, in a solid state, in combination with any suitable material, such as black lead, &c. The compounds are made up in forms suitable to be used in ever-pointed pencils, &c. The materials to be marked should be written on while damp. *Patent completed.*

2317. B. NICKELS. *Improvements in electric telegraphs.* Dated October 16, 1858.

This consists in using wires not electrically insulated from the water, and in so constructing and arranging an electric telegraph between two places separated by water as to use the intervening water in forming the battery employed for working the telegraphs. *Patent completed.*

2318. W. CLAY. *Improvements in combined thrashing and dressing machines.* Dated October 18, 1858.

This relates to operating upon the corn after it has left the drum of the thrashing apparatus. On leaving the drum the straw is received upon shakers, to which motion is given by a crank shaft. The shakers are supported upon rocking bars which cause the shakers when acted upon by the cranks to have a tossing motion, which throws the straw out at the end of the machine. The grain and chaff is received upon an inclined vibrating trough the whole length of the machine, at the lowest end of which trough there is a riddle. A current of air from a fan-blower drives the chaff out at the hinder end of the machine, while the grain falling through the riddle passes into a box at the side of the machine from whence it is raised by an endless chain of buckets into a hummeller through which it is led to the opposite side of the machine where it falls into a vibrating riddle box attached to and moving with the vibrating trough. Within this riddle box there are two riddles, one above the other, and a screen beneath; while passing these riddles the grain is exposed to the action of a second blast to drive off chaff, &c., not before got rid of. The motion of the riddle box causes the small grain and seeds to pass through the screen to one spout, while the best corn is separated and delivered through another. *Patent completed.*

2319. J. A. MASON. *Improvements in washing machines and apparatus for wringing and mangling.* Dated Oct. 18, 1858.

This washing machine consists of a box in which the linen, &c., is placed in layers separated by corrugated plates or frames made of wicker work, wood, etc., every alternate frame being moved backwards and forwards by an eccentric spindle in a direction opposite to the motion of the intervening frames, and to the directions of the corrugations thereon. The frames are held down so that the pressure can be regulated. The wringing and mangling apparatus consists of two or more rollers affixed near one end of the box, and the necessary pressure is obtained by causing the box to act as a weight upon the axles of the rollers. *Patent abandoned.*

2320. W. A. F. POWELL. *Improvements in stopping or closing jars and bottles.* Dated October 18, 1858.

The inventor forms the stopper with a shoulder on its underside which fits on to a corresponding seat within the neck of the jar or bottle; an interposed washer of india-rubber, &c., making an air and water-tight joint when the stopper is pressed home. On the upper surface of the stopper there are two grooves at right angles to each other, for the reception of a string or wires, which being passed round the neck of the jar or bottle and tied over the stopper secures it tightly in its place. *Patent abandoned.*

2321. C. WEST. *Improvements in the mode of insulating and covering wire.* Dated October 18, 1858.

The patentee claims, 1, the mode of applying a solvent to the india-rubber covering of a wire as described for causing the folds of india-rubber to adhere together, and effecting a more perfect insulation of the wire. 2. The mode of subjecting the india-rubber covering of a wire to the action of a moist heat for causing the folds of india-rubber to adhere together, and effecting a perfect insulation of the wire. 3. The covering of insulated wires with yarns of fibrous material saturated with a composition for preserving such fibrous material, and causing it more effectually to protect the insulated wires. *Patent completed.*

2322. R. TIDMAN. *Improvements in machinery or apparatus for paying out and for raising electric telegraph cables.* Dated October 18, 1858.

This consists in the use of floating rafts or platforms for carrying and delivering the cables when paying them out, and for winding cables upon when it is desired to raise them. The cable passes over horizontal rollers on the lightest or aftermost raft to facilitate the delivery of the cable. The rafts are towed by a steamer. *Patent abandoned.*

2323. R. A. BROOMAN. *Improvements in the manufacture of small chains and links for the same.* (A communication.) Dated October 18, 1858.

Here a quantity of metal wire is wound upon a reel, and the end of it is led between tension rollers to a holding and cutting apparatus moved by a cam. Between the tension rollers and the cutting apparatus a nipping contrivance is placed to prevent the wire flying back when it is cut. The wire next passes through a guide hole, and then comes between the two parts of a forked mandril which is moved round by a pinion driven by a lever. The motion of the mandril gives the first bend to the wire by winding it partially round the said mandril. A kind of die is then advanced by another cam, shears off the bent piece of the wire, and, still advancing, gives the second bend to the same. A spring arm or presser is then moved against the first bend and forces the wire around a second mandril, completing the link. The second mandril is then pressed out of the link by a cam acting upon a lever attached to it or otherwise; the die is drawn back and all the parts return to their first positions, the finished link being at the same time passed out into a receiver. This is the complete process of making the single links; but if the links are to be formed continuously in the form of a chain, a kind of pincer or tool with one point barbed is interposed between the guide hole before mentioned and the first mandril, and is worked so as to place and keep each link within, or looped to, the adjacent one. *Patent abandoned.*

2324. K. H. CORNISH. *A new mode of advertising.* Dated October 18, 1858.

The inventor prints one address on a sheet of paper, or a number of different notices in squares or other divisions, and gives away this printed paper for use in the water-closets of Government offices, banks, railway stations, and other large establishments. *Patent abandoned.*

2325. W. E. NEWTON. *Improvements in apparatus for lighting gas and other lamps.* (A communication.) Dated October 18, 1858.

This consists in lighting lamps by electricity, or by the discharge from a galvanic battery. *Patent abandoned.*

2326. A. W. DRAYSON and C. R. BINNEY. *Improvements in submarine telegraphic cables.* Dated October 18, 1858.

The patentees use a much thicker wire than usual and cover it with silk, or other fibrous and non-conducting material. This silk, &c., is secured on the wire by a solution of india-rubber, &c., and the wire thus protected is enclosed in a tube of vulcanised india-rubber, so as to leave a vacant space around the enclosed wire, which thus will be enclosed in a kind of tunnel. To compensate for any undue strain on the cable, and to impart to it a certain amount of elasticity, they introduce lengths of cable from half-a-mile to a mile long, constructed upon such a principle as will admit of such lengths elongating to a certain extent when subjected to any undue strain. *Patent completed.*

2327. J. SMITH. *Improvements in rough-shoeing beasts of draught and burden.* Dated October 18, 1858.

This consists in the use of a plate or ring to which clips are attached to fit the outsides of the shoes of horses, and by causing these clips and the plate or ring to be drawn together, roughing pieces, or a snow-plate are fastened tightly upon the shoe, and thus the feet of the animal are prevented from slipping or being clogged by snow. *Patent completed.*

2328. E. WALKER. *An improved filter.* (A communication.) Dated October 19, 1858.

This invention is not described apart from the drawings. *Patent completed.*

2329. J. WHITWORTH. *Improvements in guns, gun-carriages, and ammunition.* Dated October 19, 1858.

This invention was described and illustrated at page 285, No. 18, of the MECHANICS' MAGAZINE (New Series). *Patent completed.*

2330. W. F. BATHO and E. M. BAUER. *Improvements in screws, worms, and wheels, and in machinery or apparatus for cutting the same.* Dated October 19, 1858.

This consists in constructing worms and worm-wheels, to work together so that their pitch lines will coincide, and that all the teeth of the worm will bear evenly on the teeth of the worm-wheel. *Patent abandoned.*

2331. J. OWEN and H. DUCKWORTH. *Improvements in looms.* Dated October 19, 1858.

This consists in placing the crank shaft as near the bottom of the loom as it can be conveniently worked, and the sword arm shaft much higher than is at present adopted. The picking motion is obtained by placing in each fly-wheel a bowl or tappet which acts as the wheel revolves on a lever connected by a rod or band to an arm in connection with the picking stick, the top of which is either at the side or passes through the slay bottom. Each lever is made to move out of the way of its corresponding bowl by a cam, and where several shuttles are used, pattern cards or lays are employed to govern the movement of the picking sticks. A damping apparatus is employed under the cloth and yarn beam. *Patent completed.*

2332. A. ALLAN, T. WHIMSTER, and R. GRAY. *Improvements in steam boilers, also applicable in part to gas meters, lamps, and lubricating and other apparatus requiring a constant liquid level, and in part to pressure-indicating apparatus.* Dated Oct. 19, 1858.

This invention is not described apart from the drawings. *Patent completed.*

2333. J. RICHMOND. *The construction of valves, applicable especially to water meters, and other instruments for measuring fluids, and all hydraulic purposes.* Dated October 19, 1858.

Here a quarter rotary valve is made of brass or iron. The chief object is to reduce friction. The valve is of the disc construction, and is so made that it can be eased off the face without loss of water or any other fluids that it may be applied to. The upper disc has a hollow box, and on being moved a quarter round will give either egress or ingress to the required passages, and at the same time will be quite tight on the faces. The spindle of the upper disc does not come through the valve, but is kept up in the lower box by a cylinder, and can be regulated as required. *Patent abandoned.*

2334. W. E. NEWTON. *Improvements in apparatus for washing clothes and other articles.* (A communication.) Dated October 19, 1858.

This consists in placing the clothes, suds, &c., in an air-tight vessel, and by a pump, or other equivalent contrivance connected with the upper part of the vessel, exhausting first the air and then the vapour from the upper part of the vessel, thereby removing the pressure from the surface of the heated water, which will be thrown into violent ebullition while considerably below the temperature of 212° Fahrenheit. *Patent completed.*

2335. W. E. NEWTON. *Improvements in the hanging and arranging of cylindrical, conical, or spiral steel railroad springs, for railway carriages.* (A communication.) Dated October 19, 1858.

This consists in arranging such springs in groups, or series of four or more springs placed in double lines vertically, so as to possess the length of elastic action whic

Digitized by Google

two series of the springs would have if placed the one above the other, while the space which they occupy vertically is very much less than they would require if the springs were placed in pairs one above the other. *Patent completed.*

2336. W. GOSSAGE. *Improvements in the utilization of alkali-waste.* Dated Oct. 19, 1858.

This comprises, 1, the separation of sulphuretted hydrogen from such mixed gases (obtained from alkali waste) and thereby obtaining carbonic acid gas of sufficient purity to be usefully applicable. 2. Means whereby alkali waste can be caused to absorb oxygen from atmospheric air, and the use of such oxidized alkali waste for the production of sulphurous acid gas, and carbonic acid gas. 3. The extraction of sulphuretted hydrogen and carbonic acid gases, also sulphur, from alkali waste by causing such waste to be decomposed by the action thereupon of such acid liquors as are obtained by the use of muriatic acid in the manufacture of chlorine. 4. The production of sulphuret of iron and sulphuret of manganese by the action of alkali waste in the acid liquors obtained in the ordinary manufacture of chlorine, by the use of muriatic acid, and the application of metallic sulphuret so obtained for producing sulphurous acid gas. *Patent abandoned.*

2337. R. A. BROOMAN. *Improvements in propelling vessels.* (A communication.) Dated Oct. 19, 1858.

This relates to the propulsion of vessels for carrying burdens, such, for example, as are used in canals, and is designed mainly to combine means of adapting the propelling surface to the various draughts of water of the vessel, with other necessary qualities. It consists in employing propellers each composed of a float-board attached to vertical rods or arms, the upper ends of which are connected to cranks, and which are combined with other rods and crank so that throughout its motion the float-board always remains vertical. The motion of the vertical rods and of the float-boards is in fact the same as if they depended from a rotating crank pin and met with no resistance. The supplementary rods and cranks are added for enabling the propeller to move in this manner while encountering the resistance of the water. The float-board is adjustable and may be readily shifted up and down the vertical rods and arms to suit the varying draughts of water of the vessel. Any suitable number of such propellers may be employed in a vessel. *Patent completed.*

2338. J. GRANT. *Improvements in constructing and arranging ovens suitable for baking bread.* Dated Oct. 19, 1858.

Here two furnaces are constructed one opposite the other, and the heat from these furnaces passes into a chamber between the two furnaces, and in this chamber are placed ovens, arranged so as to leave spaces between the ovens and the end and top and bottom of the chamber, and also between the ovens themselves, so that the products of combustion from the furnaces in passing to the flue which leads from the top of the chamber comes in contact with three of the sides, and with the top and bottom of each of the ovens. The ovens are constructed of wrought iron plate. *Patent completed.*

2339. W. RIDDLE. *Improvements in packing or forming merchandize or goods into bales.* Dated Oct. 19, 1858.

This consists in packing goods into bales by compressing them as heretofore, and securing them when so compressed by bands of iron, each band covered with a textile material saturated with a solution of india-rubber. *Patent completed.*

2340. L. STIEBEL, and C. F. O. GLASSFORD. *Improvements in machinery for moulding washing blues, and other materials while in a plastic state.* Dated Oct. 20, 1858.

Here the inventors effect the moulding of the plastic material by dies formed of several pieces, the lower die having a central portion that rises after each stroke sufficient to relieve the material from the lower die worked by an eccentric or crank motion. The dies while in use are kept heated by jets of gas. The material is supplied to the dies by a cylinder having a lower aperture through which the material is caused to exude by the action of an archimedean screw. *Patent abandoned.*

2341. R. D. CLEGG. *Improvements in screws.* Dated Oct. 20, 1858.

This consists in making screws of such form that they can be fixed or screwed without a hole being first made for their reception. The patentee effects this by making a part of the screw similar to a gimlet. *Patent completed.*

2342. P. C. STORTZ. *Improvements in the materials of photographic plates.* Dated Oct. 20, 1858.

This consists in substituting prepared copper or other material, plates, panels of wood, millboard, canvas, or other materials having oiled or varnished surfaces, such as are usually used for painting upon in oil, for the ordinary materials upon which photographic images are deposited or printed. *Patent abandoned.*

2343. R. GRIFFITHS. *Improvements in baths.* Dated Oct. 20, 1858.

This invention was described and illustrated at page 281, No. 18, of the MECHANICS' MAGAZINE (New Series). *Patent completed.*

2344. T. TWELLS. *Improvements in machinery for embroidering or ornamenting woven, looped, or laced fabrics.* Dated Oct. 20, 1858.

This consists, 1, in the use and method of action of a needle with a single barb, which pierces the fabric to be ornamented; 2, in causing the needle to revolve, so that the back of the needle always stands in the same direction as the fabric is moving to form the required pattern; 3, in having a bobbin or spool with a hole through its centre to allow the spindle containing the needle to pass through; also in having a small head upon the bobbin or spool with two holes, one for the needle to pass through, and the other for the extra thread to pass through; 4, in placing one or more needles out of the centre of the needle spindle, so that in revolving stitch by stitch it will describe a greater or less circle, according to the required pattern. There are various modifications included. *Patent completed.*

2345. J. WAINWRIGHT. *Improvements in ventilating houses and other places.* Dated Oct. 20, 1858.

This consists, under one modification, in ventilating houses, cabins of ships, and other places, by forming holes in the sash frames, and placing over these holes metallic plates or screens. *Patent completed.*

2346. S. T. CLARKE. *Improvements in apparatus for crossing bankers' cheques and drafts.* Dated October 20, 1858.

This relates to crossing banker's cheques by punching out portions of the paper. The apparatus consists of a press body with a vertical slide which is steadied and guided in its movements by one or more guiding feathers formed upon it, such feathers fitting into corresponding grooves or slots made in the inside of the socket within which the slide works. At the bottom of the slide is fitted a metal block, to the under surface of which is secured a series of fine punches arranged in the form required for producing the parallel lines and words required. These punches are so secured to the block that any one of them may be removed if damaged and replaced by a new one without destroying the entire die. *Patent completed.*

2347. C. C. ALGER. *Improvements in cupola furnaces.* Dated October 21, 1858.

This invention is not described apart from the drawings. *Patent abandoned.*

2348. J. and S. MARLAND. *Certain improvements in power looms.* Dated October 21, 1858.

This consists, 1, in certain variations in the letting off motion. 2. In variations in the taking up motion. 3. In the application of a clutch-box or ratchet motion to the warp beam, to facilitate the tightening of the warp when required. 4. In the application of an improved easy motion to relieve the shuttle from the pressure of the swell at the moment it is being thrown through the shed. These several improvements are not described apart from the drawings. *Patent completed.*

2349. P. CLERC and A. PIAGET. *An improved method of winding watches, chronometers, and time-pieces without the use of a separate key.* Dated October 21, 1858.

Here a piece is cut round the wind-up hole, and a piece of the same metal and shape is introduced into the hole and fitted to the square or pipe. Then a handle forming part of the round plate is raised, and when held with the thumb and fore-finger will wind easily. The handle is then shut down level with the dome of the watch, so that it is not seen, and by that contrivance the watch is preserved from dust. *Patent abandoned.*

2350. C. W. WILLIAMS and G. EYTON. *Improvements in the construction of locomotive and other steam boilers.* Dated October 21, 1858.

This consists in giving the tubes or flues of tubular boilers an increased diameter with an increased run or passage along which the products of combustion pass to the chimney. The tubes or flues are furnished with heat conductors and heat agitators by which their absorbing surfaces are rendered more efficient and an increased amount of water vaporised. Provision is also made for the introduction of the required quantity of atmospheric air with an adequate space for the admixture and diffusion of the air and gases, and for which purpose a separate chamber will be provided. The chief feature of the invention is the combination of the several parts. *Patent abandoned.*

2351. J. M. NAPIER. *Improvements in printing presses, and printing machines.* Dated October 21, 1858.

In the common hand press used for letter press or raised surface printing, the patentee constructs the frame of the hand press all in one casting, including the feet upon which it stands to raise it to a convenient level from the floor. The table upon which the type is placed is not so deep, nor is it ribbed up so strongly as those usually employed, which sustain the whole of the pressure (when the impression is taken from the type) upon two bars which slide in the bed or guide rails, but it is provided with a number of bearing strips in addition to the usual guide bars. These bearing strips are correctly planed so as to rest upon opposing bearing strips upon the bed below, which are also planed true, and so arranged as to support the table against the pressure more generally over its surface, the bed thus taking its usual strain, while the table, being well supported by the bearing strips on the bed, may be made much lighter and will at the same time present a more rigid surface. He makes the platten in one casting with the guides which rise up from it for steadiment against the top of the press frame, instead of the plan at present adopted of bolting these guides to the platten. The invention also includes other modifications. *Patent completed.*

2352. E. B. HORN. *An improved compensation apparatus for a hair-spring balance for a watch or time piece.* Dated Oct. 21, 1858.

The purpose of what is termed the chronometer balance is to compensate for the stretching of the hair spring caused by different degrees of temperature. Instead of the chronometer balance, or any such contrivance making part of a balance wheel of a watch, the inventor employs what may be termed an expansible or compensating spiral cord, separate from the balance wheel, and formed of two strips of metal laid side by side, and united together where they touch one another, one of the strips being made of brass, while the other or outer one is constructed of steel. *Patent completed.*

2353. G. REDFORD. *A circular and self-acting cartridge pouch.* Dated Oct. 21, 1858.

These pouches are made in a true circular form with rounded ends and sides so as to fit the body. They are made self-acting by a flat or zig-zag wire spring placed inside of the pouch. They are composed either of leather or papier maché japanned or covered with leather; or when great strength is required of a combination of strong linen or cotton cloth, canvas, or thin metal. *Patent abandoned.*

2354. J. BALDWIN, Jun. *Improvements in files or holders for papers, letters, bags, and other similar articles.* Dated October 21, 1858.

The patentee attaches, by screws, a metal plate to a shelf or rail of wood. At the foot of this plate he affixes a long needle point to receive the papers or bags. At the top of the brass plate is attached a spring, tightened to the plate by a small set screw and collar; the opposite end of the spring may be forked, or it may be furnished with a padded shield or cap, or the end of the spring itself may be turned up to form a protection for the point upon which the papers or bags are pierced. The spring thus serves to keep such papers, &c., upon the needle until required for use. *Patent completed.*

2355. R. A. BROOMAN. *Improvements in knitting frames.* (A communication.) Dated October 21, 1858.

According to this invention, all the parts now forming knitting frames remain, but the motions thereof are produced mechanically, so as to make them self-acting. By a repetition of parts along a frame, a great number of similar fabrics may be produced at one and the same time. The drawing shaft runs along the front of the frame, and through bevel gearing and an inclined connecting shaft, motion is communicated to another shaft with eccentrics, which are arranged upon it in such manner as upon the revolution of the shaft to set in motion levers and arms, which in turn produce all the movements now effected by hand. *Patent abandoned.*

2356. R. A. BROOMAN. *Improvements in apparatuses for regulating the supply of fluids.* (A communication.) Dated October 21, 1858.

This relates to cocks or valves for supplying fluids to cylinders, gauges, pipes, and other vessels from which it is desirable to allow the contained fluid to escape when the supply is cut off; and the invention consists in employing an eccentric cock or valve with two or more faces, which bear alternately against vulcanised india-rubber seats, when the spindle of the eccentric is turned, in such manner that when the supply-port or passage is opened, an escape-port or passage is closed, and *vice versâ*. The spindle is packed with compressed vulcanised india-rubber, and the cock or valve seats, together with the packings of all other outlets and inlets to the body of the apparatus, consist of blocks of vulcanised india-rubber, compressed by bolts or screws. The spindle of the cock or valve may be turned by any suitable means. Apparatuses constructed as before described may be applied to gauges, water-pillars, hydraulic cranes, and to various other purposes. *Patent abandoned.*

2357. R. A. BROOMAN. *Improvements in cocks, taps, and other apparatuses for regulating the flow of fluids.* (A communication.) Dated October 21, 1858.

The object here is so to construct cocks, taps, &c., for regulating the flow of fluids that their flow may be instantaneously permitted or intercepted, that the joints may be always fluid tight, that contraction and expansion of the apparatuses from varying temperatures and other causes may be provided for, and that certain of the parts may incline themselves to each other without injuring the action of the apparatuses; and the invention consists in certain methods of applying india-rubber in the construction of such apparatuses. *Patent abandoned.*

2358. J. H. JOHNSON. *Improvements in apparatus for lubricating railway axles and other bearings.* (A communication.) Dated October 21, 1858.

This consist in employing a capillary pad composed of wool, cotton, &c., combined with a metallic conducting spout which is pressed by springs against the underside of the enlargement of the journal of the axle or shaft. The pad is placed above the level of the oil in the reservoir, so that it will remain in a comparatively dry state. *Patent completed.*

2359. J. BURRIDGE. *Improvements in fire-lighters.* Dated October 22, 1858.

This consists in making perforated fire-lighters from solid wood by the use of tubular saws, or by cutting, boring, or drilling. It also consists in a method of cutting bundle fire-wood by means of a cutting form, in connection or not with the tubular saws, cutting, boring, or drilling instruments. *Patent abandoned.*

2360. E. WHITEHALL. *Certain improvements in machinery for the manufacture of cap fronts.* Dated October 22, 1858.

This relates to certain improvements upon the details of a former patent, and is not described apart from the drawings. *Patent abandoned.*

2361. J. and W. BAGNALL. *An improvement in the manufacture of iron.* Dated October 22, 1858.

This consists in forming the piles by first passing the iron between rolls or cylinders with grooved surfaces, so that pieces of iron may be obtained with grooves on their surfaces; and these being superimposed or piled, their grooves will fit into each other, while by using one grooved and one smooth roll in conjunction, pieces grooved on one surface only will be produced to form the top and bottom of the pile, and present flat outside surfaces. On submitting the piles thus formed to the usual subsequent rolling operation, better distribution and superior texture and quality of iron will be obtained. *Patent completed.*

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, JUNE 3, 1859.

THE COINAGE OF THE REALM.

WE learn with much satisfaction that the articles on the state of the coinage which have been published in our columns during the last few months, and quoted in the *Times* and other journals, have met with the grave consideration of the Government, and that steps are being taken to remedy the inconvenience of which, with such good reason, the public have long complained. As regards the copper portion of the metallic currency, we have it on the best authority that an immediate improvement is contemplated, namely, the substitution of bronze pieces of the value of one halfpenny each for the old-fashioned and eccentric varieties of halfpence now in circulation.

This movement, we trust, is but the prelude to a complete and radical change in the inferior currency generally, and to a gradual reform of the superior currencies. We have pointed out the evils besetting the existing coinage, and in urging the application of remedial measures, have shown in what way to apply them with any chance of success. It is true that the English community are not gained over readily to new systems and plans, however clearly their value may be demonstrated, but in the matter of the coinage there must be few amongst us who are not anxious for a complete remodelling of it, or who would fail to applaud the Treasury and the Mint for commencing the good work. It will be our province to remind the authorities of both places should they falter in their onward movement that the public eye is upon them, and that with the means they have of effecting the reform desired, delay will not be regarded favourably.

ARMS FOR OUR VOLUNTEER RIFLEMEN.

As the gentlemen of England have made a sudden resolution to become riflemen, the Lord Lieutenants and Deputy-Lieutenants of counties have to perform a very important duty in making choice of the arms which shall be put into the hands of their respective corps; and as they run some risk of being misled in this matter, we will make reference to a fact or two for their guidance.

In the first place it is very evident that, notwithstanding the many and great improvements which breech-loading rifles have lately undergone, their immediate adoption cannot be recommended. Five or six years hence, or perhaps before, we shall doubtless have tested and modified them sufficiently, and have so far adapted the cartridge to them, as to enable us to substitute them on all desirable occasions for the muzzle-loading arm. But meanwhile we must content ourselves with the latter for general service. Turning, then, to the rifles already in use, from which alone we can prudently select a weapon for our volunteers, we find our choice limited to two—the Enfield and the Lancaster rifles—the comparative merits of which have been put beyond all question by actual service in the field of battle, as well as by the severest tests of target practice. Under many circumstances the Enfield arm fails utterly, often in the midst of the fight; under all circumstances it is liable to refuse the cartridge after a few rounds. The cause, or we may say the causes, of this are now well understood, and are known to be such as we have no present hope of remedying. On the other hand, the oval-bore Lancaster is entirely free from such defects. In the hands of our artillerymen it has repeatedly demonstrated its superiority to the Enfield in point of accuracy, and in late campaigns in India it has in no instance failed, although it has been put to the severest duties. We need not insist further upon this, because the oval-bore Lancaster is recognised as the one and only unfailing weapon with which the ordinary service ammunition can be used. This being the case, and it being manifestly desirable that the volunteer rifle corps should be so armed that they may use the service ammunition if called upon to act, it becomes evident that the Lancaster rifle is the best weapon which such corps can adopt.

With these facts before us, we have to account for the circumstance that in the Circulars on Volunteer Rifle Corps, issued from the War Department, the Enfield, and not the Lancaster, is the rifle recommended. Why is this? The reason appears to us to be sufficiently plain. It must be evident from what we have already said, that General Peel and his colleagues would gladly replace the Enfield by the Lancaster weapon throughout the regular service. But then they have an immense stock of Enfields in hand; so many that, notwithstanding the disparity between the number of our troops and those of France, we probably have eight or ten rifles for every one possessed by the French—a fact which has to a certain extent resulted from the incapacity of French manufacturers to compete with our own in the art and mystery of gun-making. Under these circumstances, what is to be expected but that an ingenious attempt should be made by the War Department to dispose of their present stock of Enfields to volunteer corps, whose mere establishment will be a guarantee against invasion, and therefore a security against their arms ever being brought to the test of battle?

In all this the officials of the War Department are doubtless acting wisely for their own interest. And if it should happen that the volunteer movement should be so far extended as to include those classes who cannot afford to buy their own arms, a legitimate means of disposing of the Enfield rifles will be provided. That it will be so extended, if the Government can manage the matter, we do not doubt. But those volunteer corps who are about to purchase their own arms may surely refuse to buy up the Enfield rifles, when the Lancaster arm, which is in reality the only model used in the Queen's Service with complete satisfaction, is equally accessible to them.

A word to the wise is enough!

THE NEW POLYTECHNIC INSTITUTION.

WHAT a happy thing it would be for England if by some blast of thaumaturgic art we could suddenly inspire all our populations with the fulness of the knowledge of science! The advantage of such an inspiration would spring, not only from the intrinsic value of the knowledge itself, but also from the banishment of those vain fancies and chimeras which now abound and predominate in the minds of the multitude. Notwithstanding all our boasted progress, for every one amongst us who is content to garnish his mind with the truths which heaven permits us to know, and with them only, there are hundreds who still retain their reverence for the idle conceits of speculation and tradition.

We have cause to be thankful, however, that the progress of knowledge, although less rapid than we could sometimes desire, is nevertheless certain and continuous. Of this there can be no doubt. We likewise know that its advance can be aided by our exertions. Every school, every educational class, every scientific institution in the kingdom, is daily spreading it abroad among the masses. In the metropolis, in particular, we have many agencies established with this express design. One of them—the Polytechnic Institution, of Regent-street—has been known for twenty years to thousands even of our country population. It has in its time done very much for the diffusion of scientific light and influence. But it has lately, we regret to say, been running a great risk of suffering extinction; and it is with the hope of averting this evil that we now address our readers.

In consequence of the lamentable accident which occurred on the premises of the Institution on the 3rd of January last, combined with other causes, it has unfortunately been found necessary by the proprietors to wind up its affairs, inasmuch as the system of management adopted ever since its establishment in 1838 has been on too lavish a scale to allow of the accumulation of any reserve fund for meeting extraordinary contingencies. The prospect of the discontinuance of an Institution which has, for many years, exercised so beneficial an influence has occasioned great regret; and a number of friends of intellectual and social improvement have agreed to join their efforts to prevent such a loss to the metropolis. They purpose forming a new society under the Acts of Parliament limiting the liability of shareholders; the society having for its object the acquisition of the whole of the property of the present Royal Polytechnic Institution, with a view of continuing the useful class of exhibitions and lectures which have heretofore been highly appreciated by the public, with such extensions and improvements as may be suggested by the experience of the past, and by an earnest desire, we believe, to uphold the high character of the original Institution.

Careful calculations lead to a confident belief that the new Polytechnic Institution will be satisfactorily remunerative to the shareholders, even supposing the receipts from the public under the new management not to exceed those of former years. This may be more readily understood when it is borne in mind that in the new Institution there will be a capital of only £16,000 (of which it is proposed to call up no more than £12,000), whereas the former company had expended a capital of £35,000. It is, of course, the duty of the directors to realize the utmost amount with the property entrusted to their charge; but a careful computation leads the promoters of the new institution to believe that the premises, machinery, and plant as they now stand will not, when offered to public competition, realize more than £4,500. It is proposed, therefore, 1st, to effect the purchase of these for the sum of £4,500; 2nd, to expend a sum not exceeding £3,000 in re-constructing the staircases, rendering the entrance-hall fire-proof, effecting certain alterations to enable the society to let off portions of the premises facing Regent-street at a rental of £300 per annum, and accomplishing other improvements which will materially tend to the success of the renovated Institution; 3rd, to apply the sum of £2,500 in reduction of the rent of £442 at present payable for the great theatre, to a ground-rent of £50 per annum; 4th, to reserve the sum of £2,000 for procuring a new charter, and for immediate working capital. On going over the estimated assets and expenditure, as stated in the society's

Digitized by Google

schedule, which is based on the accounts of the late Institution and the experience of those best acquainted with its management, we find that the dividends anticipated to be secured to shareholders, exclusive of one per cent. for a sinking fund, amount to nearly six per cent. on the capital proposed to be called in. The projectors of the new Institution profess, however, that they have not so much in view the realisation of a highly profitable investment as the upholding in the metropolis of a class of scientific attractions and intellectual recreation, the loss of which would be lamented as a great public evil.

"The new establishment will combine," we are told, "with the most useful and interesting of the attractions which raised so high the reputation of the late Polytechnic Institution, various new features tending still more efficiently to improve the moral, intellectual, and physical condition of the people. In order the more effectually to secure the maintenance of this principle it is contemplated to form, if possible, under the patronage of His Royal Highness the Prince Consort, the patron of the late Institution, a body of vice-patrons, to be selected for rank and station, or for eminence in philanthropy, education, and the branches of knowledge specially furthered by the Polytechnic Institution. The vice-patrons to elect a board of visitors who will inspect the institution with a view to maintaining its activity in the right direction." The following are among the arrangements which are intended to be adopted, subject to such modifications as practical experience may suggest to the Board of Management, viz.—"To gather information of, and, if possible, to obtain for exhibition, every genuine novelty in science, art, or industry which may appear in this or any other country"—which, we beg to say, is far too large an undertaking, notwithstanding that it is hoped to obtain for this purpose "the assistance of a committee of hon. referees of well-known competency in the several branches of science and art, and whose names will be a guarantee that little is omitted that might be desirable, and nothing admitted that might be undeserving." An efficient staff of demonstrators will be employed in explaining the objects exhibited; competent professors will deliver popular lectures on the most appropriate topics of the day; the economic museum or collection of illustrations of household and health economy, for which considerable materials have been collected and partly arranged in the western portion of the Polytechnic building, will be gradually developed so as to form, as far as practicable, a complete repository of useful knowledge for every-day life. A series of lectures will be delivered in connection therewith, their design being to teach the working classes how they may materially improve their condition by a judicious management of their expenditure. Special courses will be organised for the practical training of housewives in the most essential branches of domestic economy. The reading-room will contain besides the ordinary books, periodicals, charts, dia rams, and other educational appliances, all those that may be required for reference in connection with the leading purposes of the establishment. It is hoped by the projectors that this department will form a convenient centre for international correspondence on matters connected with the well-being of the industrial classes, according to the plan adopted by the Philanthropic Congress held at Brussels in 1856.

They also propose that the efficiency of the Polytechnic laboratory, both as a school of chemical manipulation and for analytical purposes, shall be carefully sustained, and in the latter department it is purposed to carry out a system of consultations, and of careful and conscientious analyses, for the detection of adulteration and fraud in the common necessaries of life, at a scale of charges sufficiently low to render them generally available. Evening classes will be established under the management of a distinct committee and with a separate fund. No pains will be spared, we are further told, for organising special and appropriate courses of lectures for those trades which may supply a sufficient number of subscribers, and every endeavour will be made to prepare worthy candidates for the trades examinations and diplomas, which it is hoped will shortly be added by the Society of Arts to the system of examinations and prizes in general education which it has organised with so much success, at the suggestion and under the guidance of Mr. Harry Chester. It may also be desirable to institute, on subscription, educational courses for being regularly attended by the boarding and day-schools of the neighbourhood in the manner practised with regard to municipal colleges on the Continent. In addition to all that we have named, and even more, the most liberal system will be pursued for the daily admission of working-men and their families by means of half-price tickets, distributed through the medium of their employers, or of the vice-patrons and shareholders of the Institution.

Having thus laid the proposals of the projectors of the New Polytechnic Institution before our readers, we ask their support for it, if, when the names of the gentlemen who are interesting themselves in the movement shall appear, they shall be deemed, as we doubt not they will, worthy of our confidence.

THE HOUSES WE LIVE IN.

WITHOUT knowing it—without even in the least suspecting it—many a fond father becomes the slow poisoner of his family, by selecting an unhealthy house to rear them in. It is exceedingly sad that it should be so. It is grievous enough to know that an absent child is liable to come to an untimely end—to be sure that the poet speaks but too truly to many a parent when he says—

"O father, wheresoe'er thou be,
"That pledgest now thy gallant son;
"A shot, ere half thy draught be done,
"Hath still'd the life that beat from thee.
"O mother, praying God will save
"Thy sailor,—while thy head is bow'd,
"His heavy-shotted hammock-shroud
"Drops in his vast and wandering grave."*

But it is in reality much more tragical to know that hundreds, aye thousands, of sons and daughters, in London alone, are sickening, fading, dying away daily, under the very eyes of those to whose care they are committed, but who are too ignorant to detect the maladies which they occasion.

Our thoughts have been turned to this subject by an address delivered last month at the Royal Institution, by Dr. Druitt, a member of the Royal College of Physicians, the official abstract of which address has just come into our hands. So interesting are the facts and so suggestive the observations of Dr. Druitt on this impressive subject, that they deserve all the publicity and all the prominence we can give them. Having alluded to the sickness, bereavement, and ruinous expense which sometimes ensue from the wrong choice of houses by private individuals, and to the disorders liable to be diffused amongst all classes from the unhealthy dwellings of the poor, he proceeded to consider the subject of houses and their influence on health, under three heads. Under the first, he treated of deficiencies of air, light, warmth, and dryness, and of the maladies of degeneration to which they give rise, of which consumption and scrofula are types; under the second, he spoke of the common typhoid fever of this country, and of choleraic disorders, and of their origin in defective house-drainage; and under the third, he discussed the conditions which give intensity and power of propagation to certain diseases, such as scarlatina and diphtherite.

Amongst the details noticed under the first head, he observed that the ground on which a house is built should have the qualities of porosity and firmness; porosity is required in order that all water charged with organic debris, which happens to penetrate it, may pass onwards and undergo that rapid oxydation which is so happily effected by the London gravel. Wherever the soil is deficient in this quality, or where beds of gravel or sand côme in contact with beds of clay, a thorough subsoil drainage is as essential for the health of man as it is for the growth of sweet herbage. Spots can be pointed out in which the subsoil is swampy, and where fever has prevailed in consequence. Moreover, the land on which houses are being built around London is sometimes raised artificially by what is called made-earth; that is to say, on a low, wet spot, quite undrained, are heaped all sorts of rubbish, road scrapings, mud, and refuse, mixed with organic debris; and over this the houses are built. Besides, the excavation of sweet wholesome gravel, and the filling in the vacuity with rubbish, has long been prevalent at the west of London, and is much to be condemned; and an instance was quoted of a house, whose rental was £400 per annum, built over a laystall of the last century, that is, a pit where every kind of impurity was deposited, and now filled with black mould mixed with sheep bones. This earth, when dried and analyzed, yielded 10 per cent. of organic matter, and was as unwholesome to build on as an old churchyard. Want of firmness might be remedied by a solid floor of concrete, after the Roman manner, which would enable houses to be built with less chance of settlements and cracks, which are causes of unhealthiness, not merely by allowing cold and damp to enter, but by permitting currents of fetid air to come from unknown and distant sources. Thin walls, too, render a house not only extremely cold, but unwarmable in winter.

Passing over the grouping and position of houses, and the width of streets, which ought to be regulated by the height of the sun in winter, we come to the internal arrangements and air supply. The last may be provided by some special ventilating apparatus; or may be left to take care of itself; but even if left to itself, it will be prudent to see that the basement-doors, and other chief apertures, are not near any source of contamination; moreover, great caution should be exercised in roofing in yards and areas with glass, as is often done, because the glass may cover over some sources of effluvia, and bring them into the house. This has been the cause of fever. The supply of air to the apartments should be large, diffused and not in perceptible draughts, and warmed, and should be so contrived as not to attract attention: otherwise persons who are afraid of pure air, especially servants and the poor, will speedily close up the apertures. The plan suggested by the Commissioners on Warming and Ventilation fulfils most of these conditions—inasmuch as the air is warmed by the heat otherwise wasted by the chimney, and is introduced in ascending currents; and care is taken that there is a

* Tennyson's "In Memoriam."

Digitized by Google

channel of escape separate from the chimney, and that the upper part of the apartments should be the coolest. Any plan for bringing currents of cold air to the level of the feet or of the bed, is to be condemned. Nothing can be a better evidence of the carelessness of our present system of air-supply to houses than the fact that much of it comes down the chimneys when there is no fire, bringing with it abundance of soot, and many, possibly unwholesome, products of imperfect combustion of organic matter.

A free supply of pure air is the *sine qua non* to persons who lead in-door lives; inasmuch as the direct influence of close bed-room air in producing scrofula and consumption has been proved incontestibly by Carmichael of Dublin; and later, by Dr. Guy. But till people have a sufficiency of food and clothing, it is a mockery to speak of pure air. Man's instinct chooses foulness before hunger; when the contact of pure air with the lungs, and of pure water with the skin, creates an appetite for food which he has no means of satisfying.

Further researches on the composition of house air are to be desired. It is evident that the amount of carbonic acid represents that of the most volatile, and probably that of the most innoxious product of the presence of living beings, and consequently the minimum of atmospheric impurity. Dr. Druitt has made several determinations which showed how rapidly the quantity fluctuated according to the amount of ventilation and the state of the wind. For example, in a small room in May's-buildings, Brick-street, inhabited by two adults and three children—

	Volumes of Carbonic Acid in 10,000 vols. of air.
April 20th. Noon; family dining	13·74
„ 21st. „ „ „	9·19
„ 24th. Room empty, door open...	3·34
„ 20th. All night	15·97
„ 21st. „	15·10
„ 22nd. „	12·27
In the Infant School-room, Curzon Schools, Mayfair, room crowded, with a window open at each end	9·46
In a bed-room unoccupied, but with the doors and windows closed all day, the quantity fluctuated between 5 and 7 volumes per 10,000.	

The list of maladies arising from cold, damp, airless, and sunless dwellings, is a long one, and is identical with the maladies caused by hunger, depraved nutrition, solitude, and grief; moreover, the effects of dark, monotonous, and decayed dwellings upon the mind must not be overlooked, inasmuch as they produce a direct temptation to indulge in spirituous liquors.

Under the second head, Dr. Druitt alluded to the great number of modes in which a house may receive poisonous vapours from sewers. If the house-drainage has not been revised during the last ten years, there may probably be every variety of imperfect and dilapidated drainage; wells that once supplied a family with water may have been converted into dead wells and receptacles of filth; and even when a house possesses a perfect drainage system of its own, it may be invaded by its neighbours: or the remains of old drainage systems may have been left by the carelessness or ignorance of workmen. Every pipe, too, of whatever sort, may be a means of bringing foul air from sewers; every such apparatus should, therefore, be examined from time to time, and be regulated with philosophical precision. The possibilities were described of the entrance of air from the public sewers into houses; either from stagnation and decomposition, or through the wind which at certain times penetrates the great sewers from the river; then, wherever a sewer ends abruptly, the gases are sure to be driven out of it, through the apertures in the streets made for ventilating purposes. The effects of bad house-drainage, and of sewer poison, are found in the prevalence of typhoid fever and choleraic maladies. The great fevers at Clapham, Croydon, Westminster, and Windsor, were all of this sort, and traceable to this cause; and instances are given of illness, year after year, visiting a family, and robbing it of one or more lives; and when too late, the discovery is made that an ancient, unknown, and decayed sewer ran under the premises. Many such sewers exist underground, not noticed in any map, and unknown to the present generation of officials; serving only as reservoirs of foul gases, which find vent through most unexpected channels. It is in vain for the physician to discuss remedies, whilst the patient is still breathing the vapours which caused the disease.

Lastly, the property which diseases have of lurking in certain quarters, and then breaking out with virulence, and acquiring a self-propagating force, was ascribed to impurity in general and to defective drainage in particular. Scarlet fever, especially, was asserted by the speaker to be caused *ab initio*, as well as to receive power of extension from this source. Thirteen contagious maladies, at the least, can be produced at will; and Dr. Druitt believes that in time epidemic diseases will be found subject to human control; and that the surest mode of protecting the dwellings of the rich is to cleanse and ventilate the dwellings of the poor.

In the parish of St. George, Hanover-square, out of 20,000 inhabitants of first and second class streets there died *at home*, in the three years 1856, 1857, and 1858, 10·78 per thousand per annum; whilst, in third and fourth class streets, there died *at home*, in those three years, 20 per thousand per annum, exclusive of deaths in hospitals and workhouses. Taking the *mews* separately, there died *at home* 15·36 per thousand per annum. The low mortality of purely aristocratic and first-class business streets contrasts painfully with that of the nest of low streets between Grosvenor-square and Oxford-street, where, owing to the crowded and unventilatable state of the houses, there is a mortality of 30 per thousand—a mortality enhanced, of course, by the deaths of the children who are born but cannot be reared in such habitations.

It is time more thought and more earnest labour were devoted to this subject, upon which not only the life and health, but the morality, the intelligence, and the whole well-being of the community depend.

ENGLAND AND HER SOLDIERS.

The following article from the *Athenæum*, written upon the appearance of Miss Martineau's new work on "England and her Soldiers," so strongly urges the considerations which we lately suggested in an article upon Tent Architecture that we reproduce it here with much satisfaction.

"The English soldier is at length regarded as more than a figure in a red, blue, or rifle-green uniform. Laymen and even women have begun to treat him as a rational reponsible being, with some of the qualities appertaining to citizenship, and with the general attributes of humanity. An army in the field is a machine, no doubt; but at home it consists of men, who must be clothed and housed, and who ought to be fostered in good moral and bodily health. Florence Nightingale with her firm and tender hand separated the list of those who fell under the stroke of actual war in the Crimea from the terrible majority that died from preventable causes. We then saw that epidemic was a greater foe to life, even during a campaign, than steel or gunpowder. But if the camp was ill provided, equally so was the barrack. It was discovered that, if Scutari hospitals and Sebastopol tents were scenes of gratuitous misery and criminal neglect, still more so were our military establishments developed in the midst of peace and continual plenty. The interior perspective opened up by a late report on barracks might well dissipate all illusion from the fancy even of a clod-hopper swinging on a gate and yearning to be seen in gold and scarlet—spur on heel and plume on head—a man of godlike mien, with the mustachios of a gentleman and the frippery of a hero. On parade, the dragoon or guard was that which New Englanders call "a great and glorious insect to behold;" but his private life, his undress habits, his dormitory, wash-tub, and refections were somewhat equivocal. Outside, all was resplendent and gaudy; within were stenches, dirt, clamour, confusion, grease, smoke, a foul atmosphere, and social abasement. Not that the soldier was deliberately maltreated. He suffered from official routine, and by no means from national parsimony. His barracks, although among the worst, were, generally speaking, the costliest in Europe; his meat rations, if monotonously salt and dry, were probably more liberal than those of the Imperial Guard in France or the purple squadron in Russia. And, after all, the results were not, comparatively, so pernicious as might have been expected. The British soldier, by whatever process, was made a clean being. Neither Zouave nor Hulans could reckon him amongst The Great Unwashed; indeed, the Hulans and Zouaves would do well not to speak of soap or water.

"Still, as Miss Martineau undertakes to show, the British soldier enjoys, at present, few securities for the preservation of health or life, even on home stations and in time of peace. In war, he has to encounter one chance of death from wounds, and five or six chances from neglect and exposure. Our readers will remember how the Coldstreams published their own narrative of suffering and sacrifice, demonstrating that the fearful chasms in their ranks were caused, not by Todleben's batteries, not by Gortschakoff's bayonets, but by maladministration. There is something peculiarly shocking in this melting away of an army. It is not without a thrill, even at this distance of time, that we think of the host that Cambyses sent into Lydia never to return; but the examples nearer our own day have been sufficiently terrible—the utter engulfing of Russian columns amid the sands of Tartary—the vanishing of the famous expedition to Khiva—the skeleton march of Napoleon's legions from Moscow—the British annihilation in the Khyber-pass—the dissolving in blood of the Light Brigade at Balaklava—the shattering of the Scotch Greys at Waterloo—the disappearance of a French division in Algeria twenty years ago after it had "fled into a storm," probably to be overwhelmed by some vast drift by the Adas. It is even more appalling, however, to think of men withering like leaves under their own tent rags, from famine and fatigue, while the holds of huge vessels gorged with supplies were close at hand. England lost in this way at Walcheren, says Miss Martineau, more troops than ever Marlborough led to battle; and we saw that halocaust repeated in the Crimea. Since then numerous reforms have been introduced, and, which is even more important, elaborate investigations have been entered upon. But Miss Martineau urges, that no exertions have as yet been made commen-

Digitized by Google

surate with the exigencies of the present day. Her argument on the economy of the question is, at all events, convincing. To glance over a summing up of losses incurred through apathy or incapacity is like reading Burke's 'Vindication of Natural Society' deprived of its hyperbole.

"It is not to be denied that, viewed on the surface, the position of a peasant appears to be bettered when he becomes a soldier. He is installed in such a dwelling-house as he never before inhabited, has better bedding, eats meat every day—this is a great change—and wears, we might think, incomparably superior clothes. Yet his health incessantly, and almost invariably deteriorates. He becomes liable to cold; his coughs return with every winter; he sleeps in less comfort; in rainy weather his heavy boots leak; in summer he is a special victim of the sun: worse than all, he sees his comrades struck off the muster-roll by death more that twice as fast as policemen, who are not proverbially long-lived. In military days like the present, this subject is nationally interesting. Miss Martineau discusses it practically and popularly, drawing her illustrations from far and wide, but chiefly from the experiences of Sebastopol and Scutari. Her volume is one that should be studied by such Englishmen as were ashamed to see their soldiers in the last war marching for ever under the Black Flag, not of Piracy, but of Pestilence."

HOW PECULATION IS PREVENTED AT THE ROYAL MINT.

THE means employed at the Royal Mint for the prevention of peculation is a subject of interest to the public, and visitors to that remarkable manufactory, bewildered with the sight of thousands of pounds' worth of the precious metals scattered around them in apparently careless profusion, inevitably ask the question of their guide, "How are losses avoided?" It will be our task to explain the arrangements in existence for protecting the valuable materials intrusted to the Queen's money-makers for conversion into coin, and to show how it happens that, under the judicious mastership of Dr. Graham, little or no loss occurs in the various manipulations to which gold and silver are submitted in their transit as ingots from the Bank of England to their return to it from Tower Hill as current coin of the realm.

At the head of each room wherein the necessary operations are carried on is a responsible officer, who has, during the day, complete control over a "stronghold" built of stone, and having an iron door fitted with two admirably constructed locks. Imagining, then, that a coinage of gold is being executed, that the whole of these strongholds are filled with rich yellow metal in its various stages of progress, that it is eight o'clock in the morning, and that all the workmen and boys are assembled, let our readers suppose that a portion of the contents of these golden reservoirs is then brought forth to be forwarded on its important mission. In order, however, that our explanation may be the more clear, we will take the liberty of numbering the rooms or officers aforenamed—as, 1, 2, 3, and 4, and then enumerate their duties and practices, so far as regards safe custody of the metal. No. 1 has charge of the Rolling-room, in which place the first change from the rough bar of the melting house towards the bright and cheerful-looking sovereign takes place, and receives from the master-melter a detachment of gold bars, with a certificate of their weight, as per Mint-office scales. As, however, it is a rule in the Mint to take nothing of the kind upon trust, No. 1 straightway causes the whole detachment, in companies of five or six, to be passed through his own scales, noting in the room journal their aggregate weight, with such difference, plus or minus, as haply he may find, compared with that with which he has been debited. No. 1 thus becomes, *pro tem*, sole proprietor of a number of bars of gold, the weight of which, to the hundredth of an ounce, he, of his own knowledge, is assured. He next gives out a sufficient quantity of them to last his workmen a given time, and locks up the rest in his "stronghold." The lamination now commences, and the rigid bars, thanks to the action of powerful machinery which never tires, and the activity of workpeople, who are paid by the piece, but who sometimes do tire, even of money-making, are attenuated until they become mere ribands. These are brought, of course, to a gauged thickness and width, their waste ends are cut off, and with all splinters, fragments, and scraps, they are made ready for weighment once more. Accurate weighing, and a perfect knowledge of the extent of any variation which may have resulted from any part of the working processes, enable the officer now to determine, to the hundredth of an ounce—the smallest decimal weight used in this branch of the establishment—whether he has received back all the gold he gave out. If *not*, a rigid search of the room, and of the work-people in it, follows. If *so*, another batch is given forth from the depths of the stronghold, whilst the ribands pass forward from iron trucks, with their appended weight, to officer No. 2. Leaving Messieurs the rollers to "break down" other bars, we will follow the ribands. No. 2 takes note of the ticketed weight, but he does not believe it, any more than No. 1 believed *his* ticket from the Mint officer. He, too, appeals to trial by *scales*, records the difference, if any, which they reveal, and delivers the material to the workers. These forthwith fall to at adjusting the ribands, equalizing them in thickness yet further, and in punching out "blanks" from end to end of them, which accomplished, No. 2 prepares to ascertain whether in altered form he, too, has received from his men just weight. Again, the scales, faithful ministers of justice, give their verdict—"honest," or "dishonest," "careful," or "careless," and the officer acquits, or admonishes, or makes search as he finds it right. Assuming that all is well, No. 2 affixes *two* tickets to the products of the operations of the day, one to pass forward with the blank pieces to No. 3, and one with the perforated strips—or "straps" as they call them in the Calcutta Mint—to the melter. Leaving the latter to deal in his own way with the scrap, let us pursue the golden pellets to officer No. 3. Again, the oracle of the Mint, the weighing beam, is applied to test the truth of the ticket forwarded, and its answer is duly registered, with differences, if any. After thus weighing the blanks in bulk, this officer distributes them among a bench of judges, who test their individual merits, and pass sentence of approval or condemnation on each—these are the automaton balances of Napier. The medium pieces are by them approved and deposited for coining in a central box, or rejected and impelled into the condemned compartment for remelting. After this operation, the blanks are gathered together and weighed in small batches of 180 ounces, or 15 lbs troy. From great accuracy of workmanship, 180 ounces of sovereigns *must* consist of 701 pieces; consequently No. 3 officer in this weighing also *counts* his embryo money. Now they are deposited—the good ones, that is—in bags, and are handed forward to officer No. 4, ticketed as before. These bags of gold, henceforth known as "journies"—from the old Norman French word, *journée*, a "day's work"—are next weighed again, then given forth for "marking," "annealing," "blanching," "drying," and "stamping"—processes which, in conjunction with a full account of the WHOLE ART OF MONEY MAKING, will be explained in successive numbers of this Magazine, commencing next week; and are then, after yet another weighing at the Mint-office scales, transmitted to the Bank of England, and thence scattered through the rivers, streams, and tributaries of general circulation.

It will be seen, then, that there are complete and distinct checks against peculation in each department of the Mint, and that correctness of weighing is the officer's sheet anchor. As regards visitors, there are notices affixed in every room, forbidding them to touch the work in progress, except when placed in their hands for examination by the messenger or guide who accompanies them, and who explains—in his own way—the manipulations going on. Thus, immunity from loss is attained. It may be stated, however, that before any workman is allowed to pass the police at the gate after once entering to his duty in the morning, he must deposit with the sergeant a certificate, signed by one of the four intelligent gentlemen upon whom, for convenience sake only, we have in this paper conferred numbers, and which removes responsibility to the officer giving it.

There is something so extremely attractive about the art of making money, and so many wrong impressions — raised by imperfect and superficial accounts given in cheap serials—are abroad respecting it, that, as we have stated, it is our intention, at once, to commence a series of articles authentic and clear upon the subject, and which shall dispel the wordy clouds in which some distinguished writers have enveloped it.

ON THE NATURE OF THE ACTION OF FIRED GUNPOWDER.

By LYNALL THOMAS, Esq., lately Communicated to the Royal Society by Dr. GRAY.

SINCE the year of 1797, when Count Rumford made his experiments for ascertaining the initial force of fired gunpowder, an account of which appears in the Philosophical Transactions of that year, very little light has been thrown on the subject. Count Rumford's experiments, valuable in many respects, afforded indeed nothing conclusive respecting it. The object of the present paper is to show the unsatisfactory nature of the present theory of the action of gunpowder, and to point out some of the principal errors upon which this theory is based. For this purpose, the results of various experiments made by the author, and which were repeated in the presence of a select committee at Woolwich, are described and explained. These experiments are held by the author not only to afford complete evidence of the unsoundness of the present theory, but as sufficiently conclusive to serve as the bases for the formation of a new set of formulæ, both correct and simple, in place of those at present in use. The initial action of the fired charge of powder upon the shot—the first movement of the shot itself in the gun, and the force exerted upon the gun by different charges of powder, and, therefore, the actual strength of metal required by the gun—are circumstances which, as the author believes, have not only been misunderstood, but for which laws have been assigned directly opposed to the truth. As an instance of this, the hitherto-received theory supposes that when a shot is forced from a gun it acquires its velocity gradually, from the pressure of the elastic fluid generated by the fired powder acting upon it through a certain space. It is also supposed that the initial pressure of the elastic fluid is the *same* in all cases (the quantities of powder being proportional), whether the gun from which the shot is fired be large or small; so that the larger the calibre of the gun, the slower the first movement of the shot is supposed to be. The result of the following experiment is given to prove that the first of these propositions is incorrect. The author placed a cast-iron shot, 3 inches in diameter and 3lbs. 14 oz. in weight, upon a chamber half-an-inch in diameter, and half-an-inch deep. This chamber was formed in a block of gun metal, and contained, when filled, one dram of powder. Upon lighting the powder, the ball was driven to a height of 5 feet 6 inches; when the ball was placed a $\frac{1}{4}$th of an inch over the chamber, the charge failed to move it. From this it is inferred that the first force of the powder is an *impulsive* force, that is to say, it imparts to the shot at once a finite velocity. In order to place the matter beyond a doubt, and to ascertain the relative force of different quantities of powder, the author caused a chamber to be made similar in form to,

Digitized by Google

but of twice the linear dimensions of, the former; he then placed a cast-iron ball of 6 inches in diameter upon the orifice of this chamber, which was filled with powder; upon firing the latter, the ball was driven up to a height of 11 feet; that is to say, to double the height of the smaller. The state of the metal in which the chamber was formed also showed the increase of the initial force of the powder; this is considered to be sufficient proof that the last two of the above-mentioned propositions are as incorrect as the first. Assuming the initial force of the powder to be of an impulsive nature, it is not difficult to understand the increase of force shown in the last-named experiment, inasmuch as a certain time being required for the complete conversion of the powder into an elastic fluid, a quantity contained in a chamber of a similar form, but of greater linear dimensions than another, must ignite in a less comparative time, the linear dimensions increasing in the ratio of the first power, and the quantity of powder increasing in the ratio of the third power, so that the flame will traverse a larger quantity in comparative less time. Thus it appears that the powder which inflames more rapidly has a much greater initial force, being more *concentrated* in its action; a quick burning powder, therefore, is better for ordnance of small length, such as mortars and iron howitzers. The different results produced by powder of different quality have, according to the author, been entirely overlooked in the hitherto-received theory. This theory, which considers the *secondary* force, namely, the elasticity of the fluid only, and takes no account whatever of the enormous impulsive, or initial force, produced by the sudden conversion of the powder into an elastic fluid, is that which regulates the system upon which ordnance are at present constructed; hence the reason why large guns are so liable to burst—so much so, that it has been said that no gun larger than a 32-pounder is safe to fire. From the variety of experiments made by the author, he arrives at the conclusion that when powder is of the same quality, and confined in chambers of similar form, but of different sizes, the initial force varies, within certain limits, in the ratio of $\frac{w^{\frac{1}{3}}}{w}$ where w is the weight of the powder, and w' of the ball. Thus were this new theory recognised, the question of the increase of strength, with increased thickness of metal, would wear an entirely new aspect. So far from the metal in large guns diminishing in strength in the proportion assumed, it will be a matter for inquiry how it resists the great strain to which it is subjected, rather than why it yields; for we find from the experiments described above, that a 68-pounder gun, which has a calibre of twice the diameter of a 9-pounder gun, must, when fired with the same proportionate charge of powder as the latter, continually be subject to as great a strain as the latter would suffer if always fired with the proof-charge, which is three times the quantity of the ordinary service-charge.

Proceedings of Societies.

ROYAL INSTITUTION OF GREAT BRITAIN.

April 8.—Sir Henry Holland, Bart., M.D. F.R.S.' in the chair. James Paget, Esq., F.R.S., read a paper "On the Chronometry of Life." The design of the discourse was, to illustrate the law that the processes of organic life are regulated with a regard to time, as exact as that which is observed by them in respect of size and weight and quantity of material employed in them; and to show that such an observance of time is characteristic of life, depending essentially on properties inherent in the living bodies themselves, and not on conditions external to them. Laws indicating the limitation of the organic formative processes, in respect of quantity, are evident in the facts that, in the ordinary conditions in which each living being is found, it and all its parts have appropriate size and weight and mutual proportion. These may, indeed, be modified by the variations of external conditions, or by events that are of the nature of accidents: but the range of possible variations is, in nearly all cases, comparatively narrow; and the boundaries are soon reached, in which changes of external conditions become incompatible with life. An instance of a corresponding limitation of the organic processes in regard to time might be noted in the natural duration of each creature's life. Observance of time may again be noted in the formative processes concerned in any of the organs whose changes mark the divisions of a life into its chief periods; *e.g.*, in the teeth. For examples of organic processes, adjusted to be complete in definite periods of time, the germination of seeds, and the hatching of eggs could be cited. Further, the provisions made by parents for their future young afford evidence of the time-regulation of organic processes, in so far as those provisions seem to indicate a reckoning of the time necessary for their completion. For example, certain turtles lay their eggs in hollows made in the sand, leave them there to be hatched, and at the time of hatching return to them for the sake of their young. It might be asked, how can these creatures and many others in similar cases, reckon on the passage of time? Most probably they do not reckon it at all; but just as the timely-attained fitness of their organization for preparing and filling their nests impelled them to those acts, so some time-regulated organic processes, taking place in them after the laying of their eggs, bring about at length a new condition, of which a dim consciousness becomes an impulse to them to return to their nests. Such an explanation would involve little guess-work; for changed organization is manifestly often the source of impulse to instinctive actions, and the parental organization does commonly change at a rate commensurate with that of the development of the offspring. And a similar reference to that chronometric processes in the body might explain many, though probably not all, other instances in which animals seem to have a power of reckoning the passage of time. The phenomena of disease, especially in fevers, agues, the consequences of injuries, and many cutaneous eruptions, would afford abundant instances of the observance of time in the organic processes. The vaccine disease might be generally watched as an illustration, being characterized by a vesicle at each place of insertion of the virus, which vesicle begins to appear on the third day, and on the following days passes through changes which are as exactly regulated in time as they are in visible characters. The changes in this vesicle are, moreover, indicative of a coincident succession of events in, or produced by, the virus inserted, which, in the blood of the vaccinated person, increases, and, incorporating itself in the vesicle, reaches its highest development and greatest inoculating power on the eight day, and then degenerates. The instances of morbid poisons would supply examples of organic processes timed to various numbers of days; and many that are completed in a day, or in given portions of a day, are traceable in the events of sleep and waking in animals (and, perhaps, also in plants), in the daily variations of the pulse, and of breathing, the returns of hunger and thirst, the regulated times of the digestive functions, &c. The most minute observances of time in organic processes might be noted in organs that have rhythmic motion, as in hearts and breathing muscles, cilia, the vacuoles of certain zoospores, as Volvox and Gonium. The instances adduced thus far might supply examples of organic processes adjusted to periods of time varying from the length of human life to less than a second. They were all examples of large classes of facts, from which might be filled up the instances of observance of other and very diverse periods of time; and in all of them, the time-rate is essentially determined, not by external conditions (though these may, in some measure, modify it) but by the inherent properties of the organic bodies themselves. In another large group of instances, those, namely, in which vital processes are completed, or attain some climax, in a year or in a set portion or season of a year, an independence of external conditions appears less evident. There likewise appear to be indications of a chronometry in the organic processes of warm-blooded animals, which corresponds with that of the seasons, but is essentially independent. And if it be so, these might form a group of facts, in addition to those diurnal variations of the organic processes, in which vital changes are set to the same rules of time as changes of the surface of the earth, yet have their own proper laws; and concerning which it might be said, that the cycles of life, and of the earth, do, indeed, correspond, but only as concentric circles do, which are drawn round one centre, but are not connected, except in design and mutual fitness. But, however this might be, all the instances of time-regulation cited in the discourse (all being examples of large groups of facts), would seem sufficient to prove, that the observance of time in organic processes is as exact and as universal as that of any other measure; that each species has a certain time-rate for the processes of its life, variable, but not determined, by external conditions; and that the several phenomena commonly studied as the periodicities of organic life, are only prominent instances of the law which it was the object of the discourse to illustrate.

April 15.—Sir Roderick I. Murchison, D.C.L., F.R.S., Vice-President, in the chair. Sir Charles Lyell, M.A., D.C.L., F.R.S., read a paper "On the Consolidation of Lava on Steep Slopes, and on the Origin of the Conical Form of Volcanos." During two recent excursions made in the autumns of 1857 and 1858 to Mount Etna, Sir C. Lyell had an opportunity of examining sections of lava-currents of known date, which had descended steep slopes, and had consolidated thereon in tubular and stony masses, the inclination of which sometimes exceeded 30°. This fact has an important bearing on the theory of "craters of elevation," it having been affirmed by geologists of high authority, that when lavas congeal on a declivity exceeding 5° or 6°, they never form continuous beds of compact stone, but consist entirely of scoriaceous and fragmentary materials. The discovery that lava is capable of forming continuous and tubular masses of crystalline rock on steep slopes, often exceeding 30°, enables us henceforth to dispense with that paroxysmal and terminal upheaval, which the advocates of "craters of elevation" legitimately inferred from their premises, for it was as necessary for them, so long as the volcanic beds were assumed to have been originally horizontal, to ascribe the whole elevation to a force acting from below, as it would have been if the uppermost layers of each volcanic mountain could be assumed to be of marine origin. In opposition to such a doctrine, Sir C. Lyell maintains that mechanical force has nowhere played such a dominant part in the cone-making process as to warrant our applying any other term save that of "cones of eruption" to volcanic mountains in general. In conclusion, the lecturer gave a brief sketch of the series of geological events which he supposed to have occurred on the site of Etna since the time of the earliest eruptions, events which may have required thousands of centuries for their development. The first eruptions are believed to have been submarine, occurring probably in a bay of the sea, which was gradually converted into land by the outpouring of lava and scoriæ, as well as by a slow and simultaneous upheaval of the whole territory. The basalts, and other igneous products of the Cyclopean Islands, were formed contemporaneously in the same sea, the molluscous fauna of which approached very near to that now inhabiting the Mediterranean; so much so, that about nineteen-twentieths of the fossil species of the sub-Etnean tertiary strata still live in the adjoining seas. Hence, as that part of Etna which is of subaerial origin is newer than such fossils, the age of the mountain is proved to be, geologically speaking, extremely modern. During the period when the volcano was slowly built up, a movement of upheaval was gradually converting tracts of the neighbouring bed of the sea into land, and causing the oldest volcanic and sedimentary strata to rise, until they reached eventually, a height of 1,200 feet (and perhaps more) above the sea-level. At the same time the old coast-line, together with the alluvial deposits of rivers, was upraised, and inland cliffs and terraces formed at successive heights. The remains of elephants, and other quadrupeds, some of extinct species, are found in these old and upraised alluviums. Fossil leaves of terrestrial plants also, such as the laurel, myrtle, and pistachio, of species indigenous to Sicily, have been detected in the oldest subaerial tuffs. At first the cone of Trifoglietto, and probably the lower part of the cone of Mongibello, was built up; still later the cone last mentioned, becoming the sole centre of activity, overwhelmed the eastern cone, and finally underwent in itself various transformations, including the truncation of its summit, and the formation of the Val del Bove on its eastern flank. Lastly, the phase of lateral eruptions began, which still continues in full vigour.

May 6.—The Lord Wensleydale, Vice-President, in the chair. Robert Druitt, Esq., read a paper "On Houses in Relation to Health," to which copious allusion is made in our leading article.

MEETINGS FOR THE ENSUING WEEK.

TUES.—*Royal Inst.*, "General Facts and Leading Principles of Geological Science," by John Morris, F.G.S., at 3 p.m.

THUR.—*Royal Society*, Election of Fellows at 4 p.m., no Evening Meeting.
Society of Antiquaries, at 8 p.m.
Royal Inst., "On the Seven Periods of Art," by Austen Henry Layard, Esq., at 3 p.m.

FRID.—*Royal Inst.*, Lecture by Professor Tyndall, F.R.S., at 8 p.m.

SAT.—*Royal Inst.*, "On Modern Italian Literature," by John P. Lacaita, Esq.

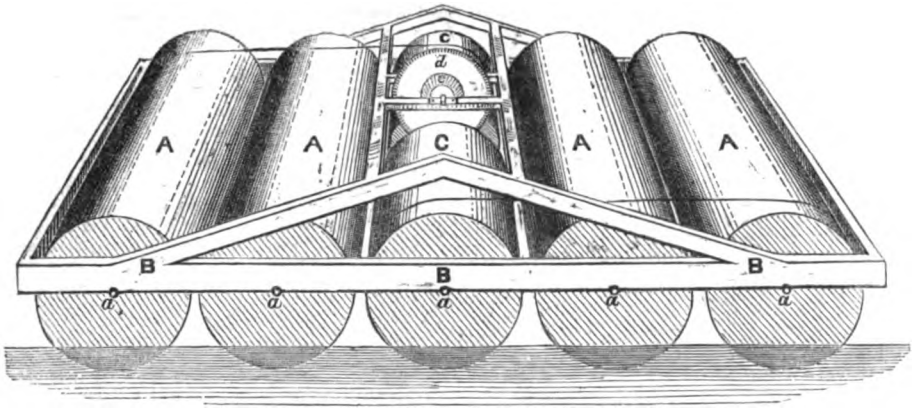
THE NOVELLO-CRAFT AND THE VELOCIVANE.



THE past week has introduced two old friends with new faces to us—the "Novello-Craft" and the "Velocivane"—both of which are intended to supersede screw steam-ships of the ordinary construction. The Velocivane is brought to our notice by a paragraph in the *Bulletin*, and, although it now comes from France as a novelty, it appears to be only the old plan of forming the bows and sterns of vessels of revolving cones, in order to escape the direct resistance of the water upon them. At this system Captain Beadon, R.N., and Mr. Paterson, have been at work for years past, with no remarkable results thus far, we believe. We will only say of it that the sounder a man's knowledge of the science of fluids and of dynamics is, the more likely he will be to deem it chimerical.

The "Novello-craft" proceeds, we are sorry to say, from Mr. J. Alfred Novello, of deserved celebrity as a music-publisher, and is designated "a proposed method for the accomplishing great speed [*sic*] in journeying over water." A paper descriptive of the same has been put into our hands, and from this we learn that the invention is "not patented in any country, but open to the free use of all." We can only say to Mr. Novello, "Thank you—for nothing!" But, before we pronounce an opinion upon this invention, let us hear what Mr. Novello has to say of it. He tells us that railroads have lately made travellers so accustomed to from 30 to 50 miles an hour, that the swiftest steam-ship progress has failed to satisfy the requirements of the age; and ship-builders have taxed their invention to modify the shape of their vessels, with the object of gaining additional speed. It was thought that the limit of profitable and safe dimensions had reen reached when steam-ships from 300 to 400 feet in length were constructed; and yet the resulting speed has practically never exceeded 14 or 15 miles an hour through the water, and has generally been much slower. The experiments of further enlargement (as in the Great Eastern, and other long vessels said to be building at Liverpool) are looked forward to with great interest; yet he believes it is not expected, even by the designers, that the speed to be attained will be more than a small increase beyond the apparent limit of 14 or 15 miles an hour. Every existing modification of boating resolves itself, according to him, into a *water-sledge*. Buoyancy is obtained by displacing a sufficient quantity of water, and such displacement is then forced *through* the waters either by oars, sails, screws, or paddle-wheels; but it has long since appeared to him that the successful attainment of high speed can only result from completely abandoning the old methods of forcing these boats or water-sledges *through* the water. He proposes to do on water what has long been done on land, viz., to place his vehicle on wheels, instead of on a sledge, the wheels being modified to the watery surface over which they have to run. "The principle being a new adaptation, I have called it," he says, "*The Novello-craft principle*, and the vehicle itself I have called a *Novello-craft*, because they are convenient terms, and also for other reasons." The engraving shows one of several modifications tried on water. "*A A A A* are four cylinders or drums made of thin sheet zinc, and they serve as the wheels to the wooden frame *B*, which rests on their axles at *a a a a a*. In the centre of the wooden frame are also *C C*, short cylinders or drums, both fixed on the same axle, with a pinion between them, and motion is given to this axle by a strong clock-spring in the box *e* attached to the cogged-wheel *d*, and tapes are passed round *C* and *A* to impart motion to the A's. The diameters of the cylinders are 7½ inches, and, when lying on the water, the weight of the whole machine (29 lbs.) sinks them into the water 1½ inch (or about a sixth) below the surface." "The displacement of water," says Mr. Novello, "(by thus sinking one-sixth) supports the whole weight, as in every precedent floating vehicle; but the novelty presented by the *Novello-craft* is, that instead of forcing this *same* displacement *through* the water, the cylinders, by being rolled over, cause successively a *fresh* displacement to take place, leaving the *previous* displacement behind." He explains the action thus:—"With sufficient power, the cylinders may be made to revolve very fast, and the displacement being no longer forced *through* water, but rolled *over* it, the speed will cease to be limited by the reluctance of the dense watery fluid to open in front, and the slowness of water to follow into the vacuum behind, but will be equal to the speed with which the *fresh* displacements are successively brought under the weight of the machine; and as the resistance to onward progress will be reduced to that of climbing the hill presented by the angle at which the cylinders meet the water, there appears every possibility for the *Novello-craft* to attain the speed of a railway train on land (50, or even 70 miles an hour), as both have to overcome the resistance of passing through the air. It will be remembered that a watery surface is a dead level, and the *Novello-craft* would not meet with varying gradients, as on a land railway. In the model *Novello-craft*, the friction of the smooth cylinders pressing against the depressed water-surface has been alone relied upon to produce forward motion, and I think in practice it will be found that no mischievous amount of slip will take place. The absence of anything like the floats of a paddle-wheel will save the waste of power caused at their first entering the water, and in their throwing up the water behind. The weight of the *Novello-craft* will make the cylinders adhere to the water, as a driving strap adheres to a drum. Getting rid of floats will probably be found to work as well as the smooth driving-wheel on a railroad."

Now, to save Mr. Novello both the time and the money which he seems disposed to squander on this hobby, as well as to preserve him from experiencing the bitterness of becoming acquainted with his error when it is too late, we at once tell him that his views are essentially unsound, and have no novelty whatever in them. Let him, or the reader, turn back to the 59th volume of the MECHANICS' MAGAZINE, and to those Numbers of it which were published on the 24th and 31st of December, 1853, and he will there discover all that he proposes forestalled and disposed of. A correspondent signing himself "N. B."—a gentleman as well able, we believe, as any man in England to discuss this subject—there gives an account of what really is no more and no less than Mr. Novello's invention.

Its author was "M. Planavergne, Professeur de Mathématiques au lycée de Cahors." "He wishes to effect," said the journal *La Presse* of that day, "such a revolution in ships as was effected in locomotion upon land, when some genius, probably unknown, displaced the sledge by a car mounted on wheels." "Our vessels plough through the water, and thrust it out of their course; he imagines them to roll upon the surface." He constructs what he calls hydro-locomotives, which, either alone or dragging a train of carriages, skim over the seas, the rivers, the canals, at the rate of 80, 90, 120 miles an hour: "they outrun the tempest." "The constituent parts of the vessel are three in number—a case corresponding to the body of a coach, four great floating cylinders to the wheels of it, and a motive power in the interior of the case." "This case is light, has two floors, and rests upon a strong frame, to which it is firmly secured. The bottom compartment contains the motive power and the provision; the upper the travellers and the luggage." The supporting cylinders were supposed to be hollow and perfectly water-tight.

At the conclusion of the articles in *La Presse*, from which the description of M. Planavergne's invention is extracted, the editor apologises to M. Mondot de la Gorce, an engineer in the service of the French Government, for having treated this invention as entirely new, although another somewhat analogous was invented by him, and noticed by *La Presse* in 1844: then quoting from a book published by him in that year, on "Chemins de Fer Flottants dans la Méditerranée," it describes M. Mondot's invention as consisting in causing a drum or cylinder, 18 feet in diameter and 30 feet long, to roll on the water; this drum is the ship, and contains motive power, passengers, luggage, &c. Large circular holes are cut in the ends of the drum for the admission of air and light, and it is propelled by a common locomotive engine, running on a line of rails encircling the interior of the drum at the middle of its length, and of course producing motion in the same way as a squirrel does in a revolving cage; the passengers are packed in and upon the locomotive, by which clever contrivance certain disagreeable consequences are avoided.

We shall not enter upon a discussion of the false views of science which enter into Mr. Novello's plans. If he possessed a proper knowledge of mechanics, hydrostatics, &c., he would never have said what he has said, or done what he has done; and without such knowledge on his part we could not hope to convince him. The truth of the matter is virtually contained in these words of "N.B":—"It seems to me," said he, "that the effect of the cylinders would be the same as that of inclined planes pushed through the water at a high velocity, for the revolution of the cylinders continually presents the same amount of surface to the water in front, at an angle depending on their immersion and diameter."

Mr. Novello will not understand this, we dare say; but, if he be a wise man, instead of spending time and money on experiments in this matter, he will spend them in the acquisition of a sound knowledge of elementary science. Meanwhile, we would recommend the letters of "N. B.," before quoted, to his attention.

Mr. Joseph Locke, M.P., President of the Institution of Civil Engineers, received a distinguished company of members and friends of the institution at a conversazione on Tuesday evening last. A splendid display of drawings and models was exhibited.

HATTERSLEY'S TYPE-COMPOSING MACHINE.

By HENRY BRADBURY, Esq.

[The following article from the pen of Mr. Bradbury, which appeared in a late number of the Society of Arts' Journal, is too interesting and important to be omitted from our columns.]

HAVING observed the interest with which Mr. Hattersley's Type-composing Machine was received at the last soiree of the Society of Arts, and having myself taken some practical interest in the machine, by placing it under a fair business-like trial for two months, I venture to offer the following remarks as to its merits for the benefit of those interested like myself in promoting the substitution, if possible and practicable, of machine for hand labour in the composition of type.

Unlike previous attempts in the construction of machines for this purpose, Mr. Hattersley's is at once simple and compact—not liable to derangement—delicate, but strong—and not requiring that type should be cast with special grooves for the purpose.

The machine consists of a horizontal table, divided into channels of sufficient width to allow the type to slide freely. At one end of these channels is fixed a metal slide, against which, by a vulcanised india-rubber cord, the type is constantly pressed, and held with sufficient force to prevent the last one in each channel from falling through an aperture immediately under it. Under these apertures is fixed what is termed the guide plate, fitted with downward channels directly under, and corresponding with, the apertures. These channels verge, for the delivery of the type, into one common mouth, which is immediately over the stick holder, in the shape of an inclined plane. A modified composing stick is adjusted to the stick-holder, in which it is made to slide longitudinally. The machine is furnished with keys, arranged as near to the present system of compositors' cases as possible. Each key, marked with the letter it represents, is connected with a piston or pusher, situated immediately above the face of the last type in the upper (horizontal) channels. The action of the key is to push the last type through the aperture leading into the guide plate, thus liberating the type, when its own gravity causes it to descend through the channels of the guide-plate into the compositor's stick: as each type drops it is guided into its place in the stick, which at the same time is pushed longitudinally forward, thereby making a place for the next descending type. A vulcanised india-rubber spring raises each piston into its original position as soon as pressure is taken off the key. Towards the end of each line a bell gives a signal, enabling the operator to judge how many more types he may play into the stick before justifying out, as in the ordinary way, the stick being in a convenient position for such purpose.

The channels of the horizontal table are calculated to hold a quantity of type equal to that contained in two pairs of ordinary cases. To avoid delay, arising from the channels becoming exhausted, the machine is provided with extra supply tables, which can be changed in a few seconds. The average speed as yet attained by the youth who has been practising upon the machine may be said to be 4,000 letters per hour, from reprint copy, including the justification. To bring it into operation would involve a systematic division of labour, as follows:—

1. Distributing type by hand.
2. Classing type, *i.e.*, arranging letters of the same character in rows.
3. Charging tables with classed type.
4. Composition.

Distributing, classing, and charging the tables, are mere mechanical operations, and can be done as well by youths as by adults. Composition from MS. or reprint, however, is an operation necessarily of a higher kind, but still capable of being done equally as well by the one as the other labour.

The following statement, comparing the old with the new system, is an example of what might be realised from the employment of machines. The calculation has been made simply with reference to the cost of the number of letters composed, and quite independent of all other extras to which all works more or less are subject, in the shape of making-up, &c.

The extra, or advertisement sheet of the *Times* consists of eight pages of ruby type. The composition amounts to 1,029,888 letters, or 205 galleys, at 4s. 3d. each, or £43 12s. Whereas, by the new system, the same number of galleys could be composed for £14 14s.; this multiplied daily, or 313 times, would yield a difference of £9,045 14s. in the year.

Again, *Knight's English Cyclopædia* consists of 488 sheets, or 7,804 pages of brevier type. The composition amounts to 83,770,000 letters, or 83,770 at 6d., or £2,094 5s. Whereas by the new system the same number of thousands could be composed for £930 13s., yielding a difference of £1,163 12s.

These results have been based upon the employment of six machines, eighteen intelligent youths, at 15s. per week, and one machine superintendent at £2 10s. The youths are qualified for either description of work—distributing, classing, charging, or composition—and are, therefore, able to relieve each other at the composing-machine. It has been ascertained that, to sustain the speed of 4,000 letters per hour, a youth or adult would require change about every three hours.

The introduction of the one system for the other would be at first attended with a certain amount of inconvenience; the two instances given, however, show that sooner or later the type-composing machine will be adopted by necessity, and will have the same relatively proportional advantage over hand-composition as the printing machine has had over the hand-press.

THE CLEARING OF DRAINS AND WATER COURSES.

MESSRS. EASTON AND AMOS, the well-known engineers, of Southwark, have patented a curious method of adapting to some convenient part of a drain, sewer, or water-course, a grating of peculiar construction, whereby any extraneous solid matters such as weeds, pieces of wood, brick-bats, stones, the dead bodies of animals, or other substances may be arrested in their progress, and removed, so as to prevent them from blocking up the water-course, and stopping the flow of the water. To this end a chamber or recess is constructed at some convenient part of the drain, sewer, or water-course, and made to extend across it from side to side. In this chamber is mounted a moveable grating in such a manner as to extend transversely across the whole of the water-way. The grating is to be formed of a suitable number of endless chains, connected together laterally in any convenient manner, and provided with projecting pins, points, or hooks. Or a number of short bars similarly provided with projecting pins may be jointed together in an endless series, so as to form an endless grating, which is to be passed round wheels or rollers mounted in the chamber or recess. This endless chain or grating should not be placed vertically, but at an inclination to the line of the drain or sewer. It will be understood that the water and liquid matters will pass freely through the endless chain or grating, but that solid matters of any great size or dimensions, or that would be likely to cause an obstruction in the water-course, will be arrested by the grating, and by causing the same to rotate (by communicating motion to the wheels or rollers on which the endless chain or grating is mounted) the pins, points, or hooks attached to the grating will be caused to lift up such solid matters out of the chamber formed in the drain, and deposit them in some receptacle provided above for that purpose.

THE THRUST OF THE SCREW PROPELLER.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—In the leading article on "The Engines of Her Majesty's Ships of War," in the MECHANICS' MAGAZINE of the 27th instant, you state that the thrust of the screw-shaft on the ship is an exact measure of the resistance that the ship meets with in moving through the water, and suggest that a simple and efficient dynamometer would register the actual amount of resistance. This is a very important subject, and I respectfully beg to suggest that you should reconsider it.

The thrust of the screw-shaft can in no instance equal the resistance encountered by the vessel—the thrust, also, of paddle-shafts is never equal to the vessel's resistance, and even the thrust against the axle-bearings of locomotive engines is below the tractive force exerted, simply on account of the *slip*.

I have often been surprised that scientific men should speak of "slip" as *power lost*; it is nothing of the kind.

If the screw or paddle-wheel could drive a ship without any slip occurring, as if they worked in an unyielding medium, the engines would work slower, but they would require to have cylinders of larger diameter, and *then* the thrust of the shaft would indicate the exact resistance encountered; there would be more friction against the bearings, but no benefit would result.

In like manner, if the driving-wheels of a locomotive were toothed and worked in racks, there would then be no slip, and the thrust of the axle would equal the hauling power exerted, but the engines would require a greater diameter, or higher pressure of steam, and no gain would ensue.

If the resistance a vessel meets with equals, say 20 tons, and the slip of the screw is 50 per cent, the thrust of the shaft would equal 10 tons only.

Owners of towing vessels might avail themselves of these facts, and, by altering the dipping surface of the paddle-boards, could work their engines at one uniform speed, whether towing or not.

I am, Gentlemen, your very obedient servant,

T. MOY.

1 Clifford's Inn, May 30, 1859.

[The principle involved in our article is a deduction from the first law of motion, and is this—when a body is in uniform motion, the forces which act upon it are in equilibrium. That is, in this case, the force (the thrust of the screw-shaft on the ship) which pushes the ship ahead, is equal to that (the resistance) which opposes its progress. We don't see very clearly upon what principle Mr. Moy's theory is based; but he holds that when there is no slip, the thrust is equal to the resistance; and when the slip is 50 per cent., the thrust is only one-half the resistance. It will follow, therefore, that when the slip is 100 per cent., which is the case when the ship is prevented from going ahead by being lashed to a wharf, or otherwise, the thrust is zero. It is quite a mistake, therefore, for engineers, when trying the engines in a wet dock or basin, to place the bow against the jetty, and protect the cut-water from injury by fenders; there can be no mutual pressure between the ship and the jetty, for there is no thrust of the screw-shaft on the ship!—Eds. *M. M.*]

MALAM'S PATENT PORTABLE APPARATUS FOR MAKING GAS.

THE great superiority of gas over every other source of artificial light renders it so desirable, that it is not now, as formerly, confined to the street, the public building, or the shop; but is extensively introduced into the dwelling-house; and there is little doubt that the practice will be all but universal in a few years hence. Hitherto, in order to be enabled to enjoy the advantages of gas, it was necessary to be located somewhat contiguous to towns or other places where there were public gas-works, but that necessity is now completely obviated by the invention of portable gas-making apparatus, and particularly, we believe, by that of Mr. Malam, just patented, not only on account of its portability, but also of the ease and cleanliness with which the operation is managed, especially when the materials are oils, fats, or bones. Any lad or other person, without any previous experience, can conduct the process with facility; but in a manufactory or other place where steam-power is used, it is the easiest thing imaginable for the man who has the charge of the engine to make gas for the supply of the establishment.

The portability of these machines may be judged of, when it is stated that one capable of supplying twenty-five gas-burners (each burner equal to ten wax-lights) occupies only the space of 2 ft. 6 in. square and 4 ft. 6 in. high. Another important feature of this invention is its adaptability for making gas from almost any animal or vegetable substance; hence wherever such material can be obtained, a beautiful and powerful illuminating gas may be made. These gas-machines are admirably adapted for the farm, where there is always a supply of animal and vegetable refuse,

Digitized by Google

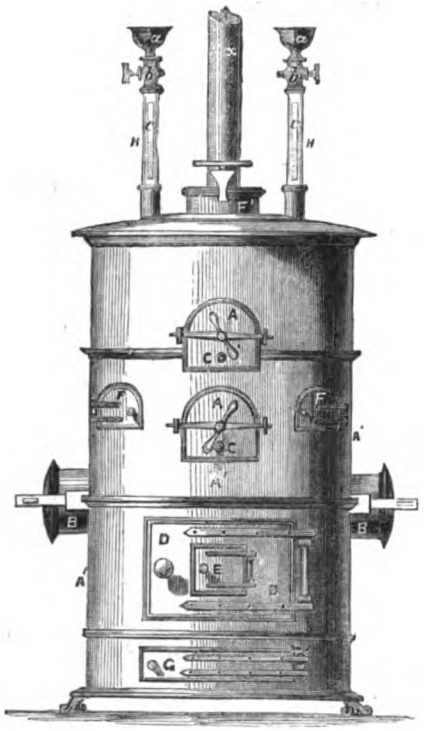
as they can be used with the most economical results, for after producing gas, the remains of the material will be found useful as a manure. In the colonies, where population is comparatively thin and organic matter abundant, nothing could be more useful than such an invention as this; it can be carried anywhere, placed anywhere, and managed by the merest tyro. On shipboard the services of this gas apparatus must be invaluable, both for the interior illumination of the vessel and night signalling. It would occupy too much space here to do more than name a few of the numerous other instances where such a contrivance would be beneficial, such as mansions in the country, small towns and villages, paper-mills and manufactories of every description, railway stations, railway carriages, lighthouses, beacons, churches, river-steamers, omnibuses, mines, &c.

The invention consists in the following new arrangement of apparatuses. Over a fire protected by fire-lumps, the inventor places two retorts into which oil is fed through gauge-tubes from above. Over these retorts in a suitable chamber he places coke, and above this chamber he fits a vessel containing fat or grease. Flues from the furnace at the bottom of the apparatus surround the coke-chamber and grease-vessel. The gas generated from the fat or grease is made to descend and mix with that from the oil, and is passed through one or more strata of cleansing material.

Instead of coke, ordinary coal may be placed in the coke-chamber, when it becomes an ordinary retort, and the gas generated from the coal may be mixed or not with that from the oil and grease.

Fig. 1 of the annexed engravings is an elevation of one of these gas-apparatuses complete. *A A* are two double retorts set in the exterior cast-iron frame

FIG. 1.



A' A'; *B* is a three-chamber retort; *C C* are sight-holes in the covers to the mouths of the retorts; *D* is the furnace-door, which has a second or smaller door *E* formed in the centre thereof. This door *E* is made for the sake of convenience, and to prevent the necessity of opening the larger door *D*, except when the furnace requires cleaning. *F F* are doors through which fuel is supplied to the furnace while the apparatus is at work; *G* is a door to the ash-pit; *H H* are tubes of glass, iron, or other suitable material, the upper ends of which terminate in cups or receivers *a a* for the reception of fatty or oily liquids employed for the manufacture of gas; *b b* are stop-cocks; *c c*

FIG. 2.

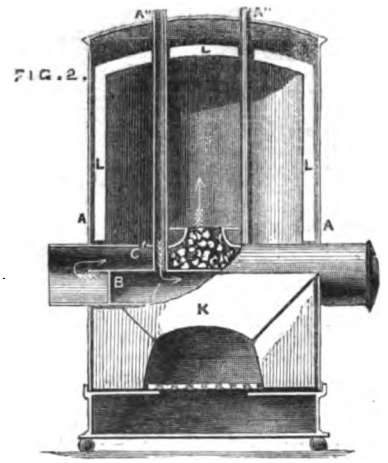


FIG. 3.

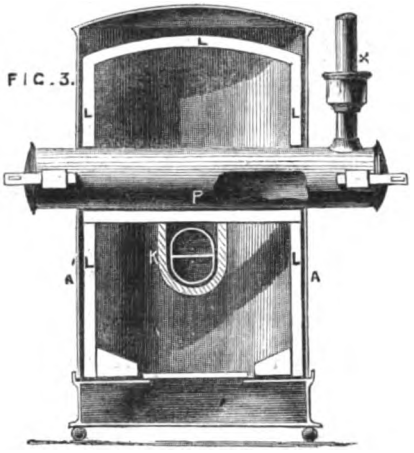


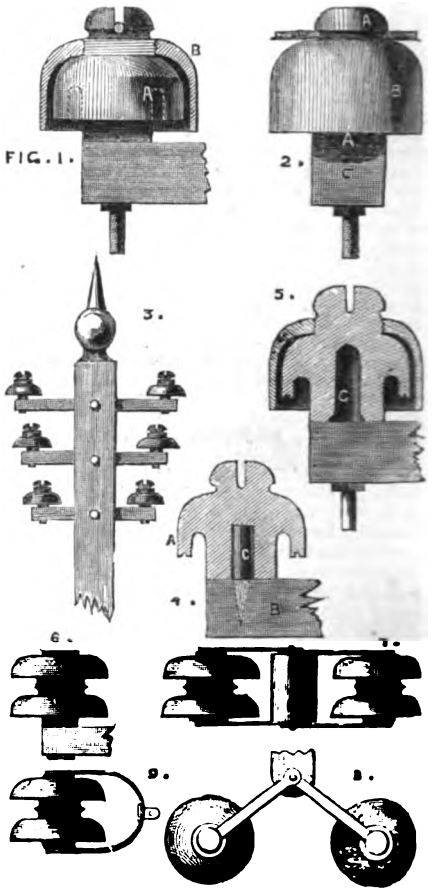
are graduated guages to show the pressure in the apparatus. Fig. 2 is a sectional elevation, and Fig 3 is another sectional elevation taken in a different position (both of these are on a smaller scale than Fig. 1). The feed-tubes *H H*, Fig. 1, are screwed or attached to the pipes *A'' A'''*, Fig. 2, which pass through the apparatus to the chambers *B B*; *C C* are other chambers above the chambers *B B*; *P* is a purifying retort. The oils or liquids are supplied to the cups *a a*, and pass through the feed tubes *H H* to the pipes *A'' A'''* (the quantity being regulated by the cocks *b b*), to the chambers *B B*, where the gas is generated from the oily or fatty liquid employed. The gas then passes into the chambers *C' C'*, where it becomes partially purified, and finally leaves the apparatus by passing through the purifying retort *P* to the pipe *x*, and thence to the gas-holder. The gas-holder preferred in connection with this apparatus is that patented by Mr. Malam on the 31st Jan., 1854, No. 242, but any other gas-holder may be used. *L L* are fire-clay cases, formed either in blocks or segments, and placed in the interior of the case *A' A'*, a small air-space being left between the case *A'* and the blocks *L*. The three-chamber retort *B* is also surrounded with a fire-clay case *K*, which is arched, and serves as a support and protection to the retort. When these fire-clay cases are once thoroughly heated a large fire is not necessary in the furnace, as the heat retained by the clay will be found sufficient for the manufacture of gas for several hours after the fire has become low. Grease or fat is placed in the retort *F F*, the vapours and gases from which descend and pass into the pipes *A'' A'''*, enter into the chambers *B B*, thence to the chambers *C' C'*, where they are subjected to the same action for their purification as has been before described, and pass off to the gas-holder through the common pipe *x*. With this apparatus gas may be manufactured from oils alone or combined with grease, or with gas from coal, or any other carbonaceous materials. Any required number of feed-tubes may be applied to the apparatus according to the number of lights to be supplied with gas.

A splendid screw corvette, the Charybdis, was launched at Chatham on Wednesday last. She appeared to us, in passing her after she was afloat, a very handsome vessel.

SIR CHARLES BRIGHT'S PATENT INSULATORS FOR OVER-GROUND TELEGRAPH WIRES.

SIR CHARLES T. BRIGHT has just completed a patent for improvement in insulators, and an improved mode of connecting insulators to posts and other supports. The following is his specification of the invention.

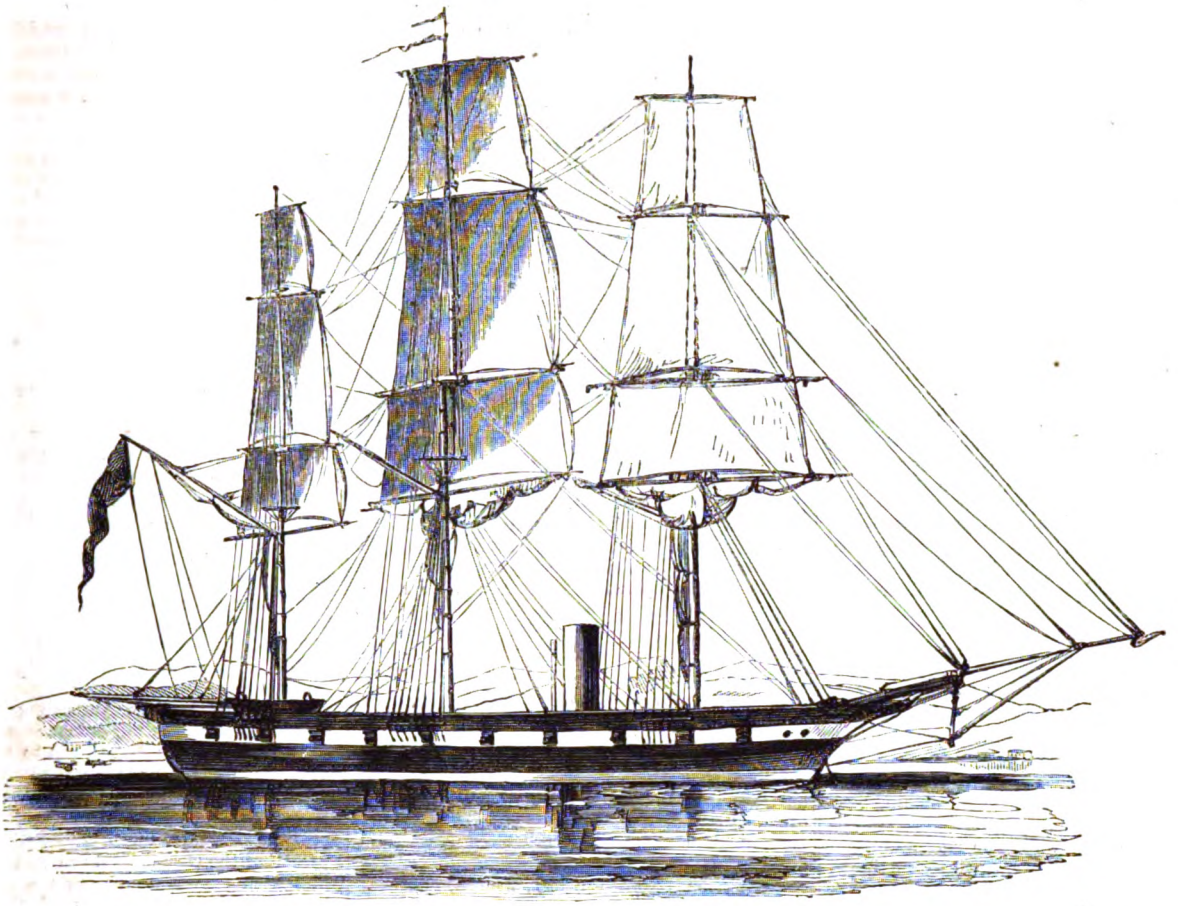
"My invention consists in protecting insulators used to support over-ground wires by combining with the insulator a roof, or cover, composed of papier maché, wood, leather, iron, gutta-percha, or any mixture thereof, or any suitable material which will act as a shield to, and protector for the insulator; by means of this cover, or protector, the degree of insulation afforded by the insulator is also augmented. Fig. 1 is a side view of a glass,



or earthenware insulator *A*, with its cover, *B B*, shown in section. It is affixed to the insulator by screwing on a thread upon the neck of the latter. The spaces between the thread of the screw should be filled up with red lead, or any cement adapted to the materials of which the insulator and cover are made, and to the climate where they are used. Fig. 2 is an external view of the insulator *A A*, and cover *B* complete, affixed to an arm, *C*, by a bolt, *a*, fastened into the stem of the insulator by a cement composed of pitch, gutta-percha, red lead, and bees'-wax. At Fig. 3 is shown the mode of applying these insulators to the system of suspending over-ground wires described in the specification of a patent granted to Edward Brailsford Bright and myself the 21st day of October, 1852. My invention also consists in connecting the insulators to the posts, arms, or other supports, by means of a slightly elastic medium, by which the difficulties arising from the unyielding nature of the cement commonly used are obviated. Figures 4 and 5 show the manner in which I effect this part of my invention. In Fig. 4 the insulator *A*, shown in section, is attached to the arm *B*, by means of an

Digitized by Google

CAPTAIN SCHOMBERG'S IMPROVED RIG FOR SHIPS OF WAR.



iron pin, *C*, which is tightly sewed with well tarred yarn, upon which the insulator is then screwed down. At Fig. 5 the insulator is shown in section, and with a cover also in section, the form of connecting pin *C* is different. By increasing the size of the hole in the stem of the insulator, a wooden pin may be used with advantage in place of the iron pin; and it is obvious that many variations may be made in carrying out this part of my invention, both in the materials (as by the use of leather, felt, or other yielding substance around the pin), as well as in the form of the insulator, pin, or cover used. I also employ, where the curves are very sharp, or the strain very great from any other cause, the form of insulator shown at Fig. 6, which may be attached to the support by an upright pin passing through it, as there shown by the dotted lines *a a*. I prefer to place a piece of vulcanised india-rubber tubing round the pin. Or the insulators may be used in the manner represented in plan at Fig. 7, and in side view at Fig. 8. In this case the strain bears evenly upon the insulators at all times, and great facility is afforded for leading down wires on each side of the insulators for testing purposes, if the great weight at which the wires are erected, or other circumstances, render it desirable to do so.

"At Fig. 9 I show a convenient mode of employing this insulator for terminating line wires. The form of shackle shown was described in the specification of the patent to which I have before referred.

"A cover may be fitted to this insulator, and when it is used to break the continuity of the line wire (as for leading into a station) where it is not convenient to place a terminal pole, a weight may be fixed to the under side of the metal strap, in order to keep the roof, or cover, in its horizontal position."

CAPTAIN SCHOMBERG'S IMPROVED RIG FOR SHIPS OF WAR.

CAPTAIN SCHOMBERG, Royal Navy, Chief Officer of Emigration at Liverpool, has designed the following new rig for ships of war. In his official capacity at Liverpool he has had ample opportunity of observing the progressive improvement made in the equipment of the noble merchant ships which sail from and trade to that port, all tending to one end, *economy of labour;* and he has zealously turned to account the knowledge thus gained for the benefit of his own profession.

There never was a time when such zeal on the part of naval officers needed so much encouragement as at present.

The restless desire for the attainment of excellence in foreign navies is undoubted; and it is only to the zeal, intelligence, and talent of our own naval officers that we should legitimately look for the production of improvements calculated to keep our navy on a footing with those of other countries.

When we look at the equipment of our ships-of-war aloft, precisely the same as it was nearly a century ago—when we compare it with the progress made in our mercantile marine, we cannot help being painfully conscious that we have been asleep!—that, considering the changes which have taken place in navigation, our navy has not kept pace with the times. It is, in this matter, refreshing to see any attempt to break out of this lethargy; and we gladly call attention to Captain Schomberg's proposed rig. We should not, in fairness, close these remarks without an allusion to one naval officer, who, although in the "non-executive" line of the service, has done very much for the sailor;* indeed, has been the first to aim a decided and effective blow at the worn-out system of ages. Captain Schomberg has availed himself of that officer's labours in his proposed rig; indeed, it is the application of the "Cunningham system" of working sails from the decks which perfects Captain Schomberg's design.

The accompanying engraving represents an iron-sided heavily-armed ship, fitted with Capt. Schomberg's proposed rig. The principle adopted by him is the "double topsail-yard rig;" that is, the topsail is divided into two parts; the lower part or topsail is set upon a yard fixed at the cap. The upper part or topsail is set above this, and works up and down the topmast in the ordinary manner. This topsail Capt. Schomberg proposes should be on the "Cunningham system," so that the sail shall be rolled up its entire depth by the simple action of lowering; and again unrolled and set to any extent required by the action of hoisting. Instead of fitting topgallant masts, pole topmasts are proposed, that is, the topmast and top-gallant mast in one continuous spar. The top-gallant sail is also to be fitted with the "Cunningham System," to roll up its entire depth, and to be deeper than an ordinary sail, so that it shall contain sufficient propelling power to dispense with the royal; thus condensing the top-gallant sail and royal into one. By this arrangement it will be seen that all the upper sails can be taken in and set from the deck without sending men aloft. So that in the event of the screw being damaged in action—say in engaging a fort—and it is desirable to withdraw from under fire by means of sails, sufficient sails can be set to draw the ship off without exposing a man aloft, which now that the use of the rifle is so general, its range so great, and its aim so precise, is a most important consideraion.

THE EFFECT OF THE INTRODUCTION OF THE ARMSTRONG GUN ON NAVAL ARCHITECTURE.

BY CAPTAIN J. GARDINER FISHBOURNE, R.N.

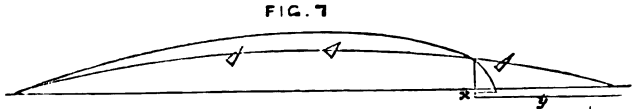
(*Concluded from p. 344.*)

ONE or two important points bearing rather upon the practice than the principles of naval architecture that should be adverted to are—

1st. The excessively destructive nature of Armstrong's shells, the certainty of bursting them, and at pleasure, and the very much greater degree of accuracy with which they can be thrown, warrant the conclusion that it would be a useless expenditure of men and guns to crowd so many as is now done in ships of the line, since small but suitable ships mounting Armstrong's guns could destroy them without much risk to themselves, if the larger vessels mount only smooth-bore guns and without undue risk if they mount rifle guns. Lofty ships will also be more open to objection as rifle guns are introduced.

The deviation of rifled shot from the vertical plane is so small that, from a steady platform, throwing a shot within the breadth of a vessel of the smallest dimensions, even at 3,000 yards, is a matter of certainty; consequently, the only hope of escape from such would be by avoiding to build ships high. The difference arising from the use of rifles compared with smooth-bore guns may be seen from a comparison of the form of their respective trajectories, which are approximately as

FIG. 7



On the assumption that these represent approximately the trajectories of shot from the respective kinds of ordnance referred to, it appears that unless the round shot falls within very narrow limits—that of the short line *x*, fig. 7—it does not take effect, while the rifle admits of considerable error in distance, equal to the line *y*, fig. 7. The great importance of this difference in ship practice can only be realised by considering, first, that the round shot is subjected to much greater error in range than is the oblong shot; and, secondly, the fact that, ships being generally in motion, there is always more or less of uncertainty in the distance of the objects fired at.

No steam fleet can be complete in its equipments without its fleet of colliers, the speed of which will generally regulate that of the steamers, otherwise they will require armed ships to convoy them. The most appropriate use of many of our old sailing vessels would be that of making them colliers, rather than selling them, or allowing them to rot. Give them Armstrong's guns on their main decks, and small auxiliary power to use in calms, they would double the effectiveness of the steamships by the supplies of power they would carry, and would themselves form no inconsiderable additional force. From their greater steadiness, and the destructive character of Armstrong's shells, they would handle a Grande Bretagne or Duke of Wellington very severely before they could close to such a limited distance that the number of guns in the latter should overbear the greater precision of the former. The number and size of colliers must be proportional to the aggregate horse-power of the steam-fleet, which shows the necessity of building vessels that will realise the necessary speed with the least amount of horse-power; not directly on the score of economy, though that would be no inconsiderable advantage, but for purposes of efficiency.* From an absence of proper adaptation, the Diadem, of 32 guns, with 800 horse power, realises little more speed than the Renown, of 91 guns, with only a similar amount of horse power, and doubtless not consuming more coal, though the area of their respective midship sections are about 10 to 13.

Yet, with or without the addition of the auxiliary force above alluded to, we may affirm that till our naval history, which now details almost uninterrupted triumphs, is substituted by records of disasters, England will not have anything to fear from a single-handed foe.* From a combination in the early stages of a war she might apprehend injury; then only because of wanting men, or because the rear of her fleets might not be open to obtain supplies of coals. Were Armstrong's guns and fittings adapted throughout our service, it would afford us a solution of this our greatest difficulty. His 70-pounders can be worked by five men as easily as the smooth-bore 68-pounders by seventeen; while in certain conditions of the sea the former could be used with effect, though the latter could not be "cast adrift" with safety, Nor is it a small advantage, physically and morally, that these five men are relieved from the labour and distraction of running the guns in and out. Even courage would evaporate with the intense exertion of working large guns, and carefulness in pointing would be at an end. In fact, the weight of men and guns moved in this operation every round shifts the centre of gravity of the ship from 12 to 18 inches, which generates oscillations in the smoothest water fatal to that accuracy which is of increasing importance. Armstrong's gun, on the other hand, working on a pivot—the recoil being provided for by a beautiful arrangement—the hustle and bustle of tackles and the exhaustion alluded to is provided against.

Again, the demoralisation which was found during the war to arise from wounds and death occurring on crowded decks will be entirely avoided by small crews.

Effective sea-going ships with iron-plated sides can be obtained only by building them for the purpose, and then narrow and deep. Plated ships we shall come to, though it might be that neither the plates nor the ships' frames should resist rifle 70-pounders, or heavier shot, at comparatively short distances; for at such distances plating becomes of much less value, as the accuracy attainable with Armstrong's guns will admit of the shot and shell being put through the portholes—the proper way, indeed, to assail, as the enemy's guns and men are collected there; but it may be that less heavy plating than that proposed may be used with advantage.

Such adaptations as the Gemappes can be but bad make-shifts, justifiable only because of having ships that ought to be utilized; to build anything like her or still less like any of our wide ships would be unpardonable, as this were to throw away the principal advantages offered by this gun.

The crew that would suffice for thirty-six of Armstrong's guns would be wholly inadequate for the large masts of such vessels as the Gemappes; or suppose ninety of his 70-pounders placed in the Renown in lieu of her hollow-shot 68-pounders, it would be absurd to draw any comparison between the two armaments, the former is so superior in range, in accuracy, in lightness, in the certainty of the action of the shells, in security in a seaway, in the limited amount of powder they require, in dispensing with tackles, and, notwithstanding the assertions to the contrary, in the destructive character of his shells. Other shells, owing to the circumstance of their centre of gravity being on one side, are subject to great deviation, and they are uncertain in bursting; many fell into the ditch at Sevastopol unexploded; Armstrong's, on the contrary, always explode. And though the hole made by their entrance is very small, this is a cause of their greater efficacy, making a small hole, and entering the wood rapidly, the hole closes after them, so that when the bursting powder, of which there is a larger quantity, explodes, its effect is greatly intensified in consequence of its being so confined, vastly more than takes place where the hole is larger, as part of the explosive force passes away through it. Consequently, were the Renown thus armed, she would have a far more effective armament; and were it not for her large masts and sails, might have her crew applied to the manning of two other 90-gun ships; reduce her breadth, and her masts and engines may be reduced in the same proportion. This also would be altering in a direction to obtain a steady platform, and, great as these advantages would be in effectiveness and in economy, they would be nothing in comparison of the priceless value of the men made available for manning other ships.

I fully believe that a saving on one such ship, if it were deemed expedient to place so many as ninety of Armstrong's guns in one vessel, including first cost and current expense of men and ship for one year only, would amount to the greater part of £100,000.

It may not be deemed advisable to reduce the crews to the extent implied in the foregoing; nor could it be so done with existing ships, though their armaments were changed, yet it cannot be that such large crews shall be retained only because of large masts and sails! ships must be built that will not require such.

At no distant day, Armstrong will suggest modifications in existing ordnance and their carriages as will better adapt them to the object for which they were intended, and admit of a reduction of the number of men required for working them; so on all accounts ships that require large masts and sails will fall into desuetude.

Cutting the Gemappes down and covering her sides with iron plate suggests a doubt of the propriety of building ships of the line, even though they were suited to undergo a similar transformation. It is very much to be doubted that this ship will prove a good sea-going ship, and yet, owing to her small breadth as compared with her immersed depth, and the large amount of ballast she carries, she will be much more likely to yield a satisfactory result than any in our service.

I had hoped to have given some proofs drawn from recent trials; if any have been tried, they are kept from us, the principal effect of which is to keep naval officers ignorant, and naval architecture unimproved.

Our dockyards having been for a long series of years the largest ship-building establishments in the world, and vessels of the greatest diversity of form having been built in them, we ought to possess an amount of experience, limited by no personal pecuniary considerations, as all experiments have been at the public expense, and a mass of facts that, if tabulated and used with ordinary intelligence, would have prevented the necessity for our copying the French floating batteries, as we are said to have done, at a cost of well-nigh half a million, and have afforded a guarantee against other eminent failures that have occurred from time to time.

The subject is vastly too important to be treated in the flippant way it has been, even by professional men—another illustration that they get into ruts which those outside are the first to discover.

I have stated my opinions decidedly, because I feel assured that the whole subject of naval architecture requires reconsideration, and that our ships should be designed on some more definite and satisfactory principle than they are; and because I feel strongly that the nation which fully adopts Armstrong's gun, and all the measures necessary for developing its great powers, will be benefited to an extent that no numerical advantage

* It has been well said by an American naval officer that *great* steam-power is of most value for running away. It certainly will not in action prove of the high value which has been given it, nor will the result justify the great sacrifices which have been made to obtain it. When such ships have used much of their coals, they roll very much, which will in action place them very much in the power of auxiliary-powered ships, if not also in those of sailing ships. If large powered steamships go into action they must come down to the terms of their opponents; and if the latter are also to make good use of their time, the speed of the former may not suffice to take them out of action in time.

* We possess a very much larger number of sailing ships than any other power; and the necessity for an auxiliary force, such as I have described, shows that these vessels should all be counted as part of our effective force, provided only that men can be obtained for them.

Digitized by Google

of ships and guns similar to those now in use can counterbalance.

In this case the invention will prove vastly more advantageous to us, as it will enable us, while increasing the efficiency of the *materiel*, to place the *personnel* of the navy on a sufficient and entirely satisfactory footing, without further taxing the springs of industry.

After the reading of Captain Fishbourne's paper the following remarks were made :—

Sir WILLIAM ARMSTRONG, Kt., C.B.—In consequence of the injunctions at present imposed to secresy, there is but little I can say on the subject of rifled guns, but there are a few points connected with the trajectory of the projectiles which I may observe upon.

In a vacuum the trajectory would be the same whether the projectile were elongated or spherical, so long as the angle of elevation and the initial velocity were constant; but the presence of a resisting atmosphere makes this remarkable difference, that while it greatly shortens the range of the round shot it actually prolongs that of the elongated projectile, provided the angle of elevation do not exceed a certain limit, which in my experiments I have found to be about 6°. This appears at first very paradoxical, but it may be easily explained. The elongated shot, if properly formed and having a sufficient rotation, retains the same inclination to the horizontal plane throughout its flight, and consequently acquires a continually-increasing obliquity to the curve of its flight. Now the effect of this obliquity is, that the projectile is in a measure sustained upon the air, just as a kite is supported by the current of air meeting the inclined surface, and the result is, that its descent is retarded so that it has time to reach to a greater distance.

With regard to lateral deflection, if from any cause the axis of the projectile should become inclined to the vertical plane, the resistance of the air operating on the inclined surface will press it to the right or to the left, according to the direction of such inclination.

The causes of the axis thus deviating from the vertical plane are somewhat complex, but are due to the manner in which the atmospheric resistance operates upon the under surface of the projectile in relation to the upper part, and upon the curved or conical end in relation to the cylindrical part. As a general observation, I may state that a rotation from left to right (looking on the upper side) will produce a deflection to the right, but the more the form of the projectile approaches that of a simple flat-ended cylinder, the less will be the amount of that deflection. In fact, when a rounded or conical end is altogether absent, the deflection will even be reversed, or take place to the left. Another cause of deflection exists in that class of projectiles which have projections upon them for the purpose of taking hold of the rifled grooves. Such projections act as fanners upon the air, but not with equal effect upon both sides of the projectile, inasmuch as the air is condensed on the one side and rarefied on the other. It becomes an important point, therefore, to determine at what part of the projectile such projections should be placed so as to produce the least possible disturbance of equilibrium affecting the axis.

The deflections of which I have been speaking are of a permanent character, but it is the variable deflections which are the most difficult to deal with. I cannot here enter upon this part of the subject further than by stating that want of fit in the gun is the principal cause which produces irregular deflections in an elongated rifled projectile.

With regard to the application of rifled guns in ships of war, I entirely concur with Captain Fishbourne in what he has stated as to the importance of a steady platform. I think also the number of guns in a ship should be very much less than at present; but that the power of each should be as great as possible. Numerous guns involve crowds of men, and produce so much smoke as to render it impossible to aim. But, above all things, it is important in introducing these guns that the training of the seamen in the use of them should be proportionate to the more refined character of the weapon; and I earnestly hope that the Government will take effectual means to ensure the adoption of a proper system of instruction.

HALL AND WELL'S TELEGRAPH CABLES.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—In answer to "an Enquirer," in your journal of the 27th inst., in reference to the use of cotton for insulating telegraph wires, we believe there is no *bonâ fide* objection to the use of cotton, or any fibrous material when perfectly pure in quality; this we know to be a fact, in consequence of the large quantity we have covered for electrical purposes. Knowing, therefore, that no objection is made to its use, we can, by our patent machinery for manufacturing telegraphic cables, turn the same to a very great advantage in the construction thereof.

First, by covering telegraphic wires by any of the known methods with cotton, we thereby lay a foundation for the india-rubber, which is very essential, as it prevents the india-rubber or gutta-percha from adhering to the wires after the process of insulation is completed. We are of opinion that when the wires are *too closely* imbedded in the insulating material, that the wires are likely to be broken when the cable is *bent* in any particular form, from the fact that the wires cannot regain their original position, more especially if gutta-percha is used for the insulation; as it is an undeniable fact, that the same becomes hard and somewhat brittle at a low temperature.

Secondly, the advantage in using a fibrous material in the process of insulation is of very great importance; as we are thereby enabled to take *nearly* all the strain off the conducting wire or wires during the process of being covered with the india-rubber, because we consider that a cable ought to be made from the beginning to the end, with very *little* strain being put upon the conducting wire or wires in the process of its manufacture.

We shall feel a pleasure in answering any questions your correspondents may feel disposed to ask in relation to cables constructed under our patent.

We are, Gentlemen,
Your most obedient Servants,
HALL AND WELLS.

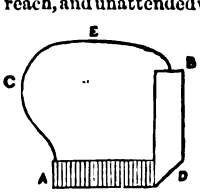
Steam Mills, Borough-road, Southwark.

ELECTRICAL EXPERIMENTS.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—In my last communication to you on the subject of the Atlantic cable*, I described an experiment made by means of a powerful electrical battery, to prove the earth to be an imperfect conducting material, to form a portion of an electrical circuit for telegraphic purposes; the experiment was made nearly half a century back, and it will not, therefore, be amiss if I describe in a few words, with your leave, a novel and interesting experiment which will be found to prove the same thing in a manner much more satisfactory than any of the experiments heretofore described by me.

In the experiments I am about to describe, the object I had in view was to dispense with a powerful battery; to make use of currents of electricity small in quantity, and of low intensity, and with an apparatus within every person's reach, and unattended with trouble; and to ascertain with facility the behaviour of these weak currents of electricity when passing through moist earth.



Procure a strip of zinc, about one inch broad, and about six inches long, bent into this shape, and that portion marked *A D* at the bottom is covered with paper, and afterwards some ten or twelve yards of small copper wire, about half the size of bell-wire, is coiled once round over the paper; it is not necessary to insulate this wire with silk or any other insulating substance, and the end of the wire is riveted fast to the zinc at the top at *B*, between plates of harder metal, or with thumb-screws secured.

This simple galvanic circle is put into a tumbler of clear water, without any acid whatever, a portion of the zinc wire at *B* being above the water; with this instrument three important experiments can be performed without trouble or difficulty. In the first experiment it will be found, after the metals are in the tumbler of clear water three or four days, that the water becomes turbid, and in about a week or ten days there will be perceived in the tumbler a copious precipitate of oxide of zinc, and which will continue increasing while the water will be diminishing in quantity. There is, therefore, as well may be supposed, a current of electricity circulating sufficient to deflect a sensitive indicator; and such is found to be actually the fact, notwithstanding the weak current of electricity. Let us now alter the arrangement for the second experiment; let the loop of wire marked *A C B* be cut in two parts at *C*, and the two ends of the wire thus separated are immersed in a second glass tumbler; clear water without acid is now put into both tumblers; under these circumstances a phenomena somewhat unexpected takes place. It will now be found that the production of oxide of zinc has ceased to be produced in the first glass, the water remaining perfectly clear; this might have been expected, in consequence of the wire being cut, and a portion of the current passing through water; but with respect to the second glass, the water in a few days will be found slightly to change colour, and finally in a week or ten days that end of the wire disconnected with the zinc will be covered with a very fine green oxide of copper, the wire proceeding from the zinc being dissolved in the pure water in the second glass; and if the two wires before they enter the second glass pass through any other vessel containing clear water, one of these wires will also be covered with oxide, namely, all that portion under water. There must, therefore, be a current of electricity circulating in this experiment, although the only indication we can have of it is the precipitation of this oxide on the wires. No sign of it can be perceived by the indicator, as was observed in the first experiment. We will now proceed to the third experiment, the instrument remaining as in the second experiment, and clear water put into both glasses; that portion of the wire situate between *C* and *B* is cut in two parts at *E*, and to the two ends of the wire thus separated copper plates are soldered, and these plates are plunged into moist earth; the action is now continued for several months, but no appearance of oxide of copper can be seen, and the first glass also continues perfectly clear; but when the plates are taken out of the earth, cleaned and pressed strongly together, then in a few weeks the oxide of copper appears as before, and becomes visible, so that in the first experiment there is but a small quantity of electricity circulating. In the second there is considerably less circulating, but in the third experiment it has ceased altogether; this would not be the case if the earth was as good a conductor as the copper wire.

I am, &c. P. M.

FEEDER FOR STEAM BOILERS.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—A short time since I saw in your journal an explanation of the principle of action of a new water feeder for steam-engines. As the object of the MECHANICS' MAGAZINE is, of course, to give a true account of every invention, I would beg leave to suggest that your correspondent's account, or explanation, is erroneous.

It is said that the action of the steam is to create a vacuum in the chambers, and that there-

Digitized by Google

fore the water runs up the pipe into the chamber between the two steam-pipes, where it is subjected to the force of the steam from the large supply-pipe, which steam drives the water out of the chamber through the smaller pipe into the boiler, after overcoming the resistance of the steam in the smaller pipe; but the reason given why the water should run up the pipe into the chamber simply because there is a vacuum in the upper chamber, and without any force upon the water, seems funny, and after assuming the chamber to be full of water, why it should not run down the pipe (its gravitation being aided by the steam-pressure above) seems quite as much so.

I do not doubt the action of the instrument, although I think it is not so simple as the plan I proposed to feed my steam-racket propeller, which plan is afterwards explained.

I would beg leave to offer the following as the more rational one, although not quite so wonderful in its action. That the water in the supply-tank is enclosed, and the surface of it is exposed to the same steam-pressure as in the boiler (which is not stated in the explanation) and that it is by this pressure the water runs up the pipe into the chamber, where it is acted upon by the steam-jet, and that the column of water in motion, with the same pressure behind as in front, overcomes the steam by its superior density, or gravity, the force of the steam being to a great extent latent.

My plan is to have a small water-tank, the bottom of which is to be above the water-surface in the boiler, the supply-pipe to the boiler having a valve, or stop-cock, to prevent the return of steam, a steam-pipe communicating with top of the supply-tank with a stop-cock, and a water supply-pipe to the tank, from any water exposed to the atmospheric pressure with a valve, or stop-cock.

The action of this feeder is very simple; a little steam is first let in to create a vacuum in the supply-tank, upon which the atmospheric pressure upon the exposed water immediately fills the supply-tank with water; the steam is then turned on so that the surface of the water in that tank is exposed to the same pressure as the water-pipe to the boiler receives, therefore both being equal, the water descends by its own gravity into the boiler.

I am, Gentlemen, your obedient servant,

JAMES PARKER.

6 Lilford Road, Camberwell, May 26th, 1859.

THE NEW STEEL STEAMER WINDSOR CASTLE.

A friend, upon whom we can rely, has kindly favoured us with the following memoranda respecting the new steel steamer built by Messrs. Caird and Co.:—The "Windsor Castle," new steel steamer, built and engined by Messrs. Caird and Co. Greenock. —Length, 190 feet; beam, 20 feet; depth of hold, 7 feet; registered tonnage, 93 tons. The boat, boiler, paddle wheels, and portions of the engines are of steel, furnished by the Blockairn Iron Company. When tried on the 28th inst. on the Clyde with a mean draught of 3 feet 1 inch, she performed the distance between the "Clock" and "Cumbræ," which is 13·666 knots, or 15·744 statute miles, in 48 minutes 5 seconds, giving a speed of 17·083 knots, or 19·679 statute miles per hour; and had the vessel not been taken considerably off her course through not being able to sight the Cumbræ the same would have been accomplished, we are informed, in under 47 minutes or at least 20·097 statue miles per hour. The immersed midship section of vessel at time of trial was about 52 square feet, the paddle-wheels on the feathering principle, 46 feet in circumference, of beautifully light proportions, each fitted with 10 floats. The boards being 8 feet by 2 feet 3 inches, were making an average of 43·3 revolutions, propelled by 2 cylinders 40 inches diameter, 60 inch stroke, cutting off steam at 12 inches—steam for ditto supplied by an upright tubular boiler of the form first introduced into the Thames by Mr. David Napier, the steam from which is led into a tubular arrangement at the base of the funnel and *superheated*. Our correspondent informs us that a delicate thermometer immersed in an oil bath gave the following results:—

11.0 a.m. steam 33 lbs. by pressure gauge, revolutions 42.

Temperat. due to 33 lbs. above the atmosphere	280·5 F.
— of steam entering superheater ...	287 F.
— — leaving — ...	353 F.
— on entering cylinder	339 F.

12.25 p.m., steam 37 lbs. by pressure gauge revolutions 44.

Temperat. due to 37 above the atmosphere	285·7 F.
— of steam entering superheater ...	300 F.
— — leaving — ...	377 F.
— on entering cylinder	341 F.

The consumption of fuel was not tested on this trial, neither could it have been with fairness to the manufacturers, Messrs. Caird and Company; the coal (Airdrie-hill) being small and interspersed with an abundance of shale, so much so as to coat the bars with clinkers in some six hours' steaming. The engines, by Government formulæ, give a combined horse power of 112·; but the actual horse power gave a maximum of 632 and a minimum of 611·6, the latter with a mean effective pressure of 18·25 lbs. to the square-inch and 44 revolutions, giving an actual of 5·46 times the nominal horse power; safety valves loaded to 40·25 lbs. to the square-inch.

Law Cases.

COURT OF QUEEN'S BENCH, Westminster, May 28.—(*Sitting in Banco, before Lord Campbell, and Justices Wightman, Erle, and Compton.*)

BETTS *v.* MENZIES.

THIS was an action in which the plaintiff, the inventor of what is called Betts's metal, sued the defendant to recover damages for the infringement of his patent, granted to him in the year 1849, for "a new manufacture of capsules, and of a material to be employed therein, and for other purposes." The action had been twice tried in this court, on the last occasion before Mr. Justice Erle, at the sittings after last Hilary Term, when the trial lasted six days. The verdict on that occasion, as at the previous trial, was found for the plaintiff; but, subsequently, a rule was granted to enter the verdict for the defendant, upon the following among other grounds—viz., 1. That the plaintiff manufactured large quantities of the capsules for sale before the date of the patent, and that the invention was not a new manufacture at the time of the grant; 2, that plaintiff's invention as claimed, or some material part of it was included in the specification of Thomas Dobbs's patent, granted in 1804. According to the plaintiff's specification, his patent metal consisted of lead and tin, which in the first instance were cast in ingots, and separately rolled out till the tin became about one-twentieth part of the thickness of the lead, and both were of a thickness suitable for making the patent metal required. The two metals, being thus reduced to their proper relative thicknesses, were laid on each other, and pressed between rollers, the effect of which was that the two metals were combined into one by the pressure, and so became in effect one sheet of metal, with a coating of tin on one or both sides, as might be required. Of the metal thus formed the plaintiff's patent capsules were manufactured and sold in large quantities, and the manufacture had also been extensively applied to many other purposes of ornament and utility. The plaintiff, in his specification, claimed, first, "the manufacture of the new material, lead combined with tin on one or both of its surfaces, by rolling or other mechanical pressure, as herein described; and, secondly, the manufacture of capsules of the new material of lead and tin combined by mechanical pressure, as herein described." It was proved at the trial that before the plaintiff's patent was sealed a large number of capsules had been manufactured by the plaintiff for sale, but not sold, and it was contended, on the part of the defendant, that this invalidated his patent. It was also contended that the plaintiff's invention as claimed, or some material part of it was included in the specification of Thomas Dobbs's patent, granted in 1804, for what he termed "Albion metal," and which was produced by the union of tin with lead by means of mechanical pressure.

The Attorney-General, Mr. Macaulay, Q.C., Mr. Serjeant Hayes, Mr. Udall, and Mr. Webster were heard on Saturday last to show cause against the rule, and in support of the plaintiff's patent.

Mr. Mellor, Q.C., Mr. M. Smith, Q.C,, and Mr. Hindmarch (with whom was Mr. Joseph Brown) were this day heard in support of the rule.

Lord Campbell said he did not think that the fact that the plaintiff had manufactured his capsules before the patent was sealed invalidated his patent. There was some delay in granting the patent, and the plaintiff had manufactured the capsules, but the invention was known only to the plaintiff and his partner, and none were sold until the patent was granted. On the other point, his Lordship said he had entertained great doubt, and had deliberated fully, and, in the result, he was of opinion that the plaintiff's patent was bad. If the plaintiff had limited his claim to the particular proportions specified his Lordship thought the patent might have been good, but, on looking at his claim, it appeared that he claimed "the manufacture of the new material, lead combined with tin, on one or both of its surfaces, by rolling or other mechanical pressure, as herein described," the combination of the two metals by pressure being the subject of Dobbs's patent. The plaintiff's patent was, therefore, invalid, and the rule to enter the verdict for the defendant must be made absolute.

Mr. Justice Wightman, Mr. Justice Erle, and Mr. Justice Crompton expressed themselves to the same effect. Rule absolute to enter the verdict for the defendant.

NOTICES.

The MECHANICS' MAGAZINE will be sent free by post to all subscribers of £1 1s. 8d., annually, *payable in advance*. Post Office Orders to be made payable to R. A. Brooman, at the Post Office, Fleet Street, London, E.C.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 5d. per line for any number of insertions less than 13; for 13 insertions, 4d. per line; and or 52 insertions, 3d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

Special Arrangements for larger or Serial Advertisements. To ensure insertion, Advertisements must reach the Office by 5 o'clock on Thursday evening each week. None can be received after that time for the ensuing number

Our Weekly Gossip.

Mr. E. T. Loseby, the well-known chronometer-maker, sends us the following suggestion:—"An optical effect, which I suppose to be new, may be developed with the gimballed gyroscope as follows: having set the wheel in motion, place both rings of the gimbal vertical, and the axis of rotation of the wheel will then be horizontal; communicate a reciprocating motion to the outer ring by moving it backward and forward with the hand, so as to cause a rotatory motion of the inner ring and axis to take place at a right angle to the plane of the primary rotation of the wheel; an object on the axis, such as the hole used for the string, will then become visible and the outline be distinctly defined in black whilst the axis is revolving rapidly. The effect referred to must not be mistaken for the ordinary appearance of the hole as it becomes visible during the rotation of the axis by placing it before the light without the second motion being given to the axis; in this case the light and objects are seen through the hole simply as the spokes of a wheel in motion permit objects on the opposite side to be seen. The secondary rotation given to the axis, which need not be quicker than once in a second, is of a tremulous character. There is nothing between the eye and the object equivalent to the disc or slits of the well-known apparatus by which objects in motion are rendered visible."

The following is the substance of a letter in the *Times*:—"A singular application of the stereoscope has recently been suggested by Professor Dove, of Berlin. If two accurately identical copies of ordinary print be placed side by side in the stereoscope, they will not offer any unusual appearance. But if there be the slightest although inappreciable difference between the copies, as, for instance, in the interval separating the same words, the difference will be made evident in the stereoscope, by the elevation into relief (or the reverse) of the corresponding space above the adjoining parts. M. Dove proposes this as an infallible means of distinguishing a forged bank note from a genuine one.

Mr. W. Gosling writes as follows:—"Your correspondent, Mr. T. Le Cheminant, of 30 Queen Ann-street, who addressed you as reported in your valuable journal last week, must not only be totally ignorant of the principles of the construction of my proposed improved gun, but also of that patented by Mr. Wm. Hobbs. If he will only take the trouble to compare the engraving and specification of my improvement with those of Mr. Hobbs's, as set forth and described at the Patent Office, Chancery-lane, London, he will find that they will not bear the slightest comparison. The favour of your inserting this letter in your next journal will greatly oblige."

It has been very evident, since the close of the last Russian War, that that country has turned much attention to the means for improving its manufactures, agriculture, commerce, and its railways, which has given rise to an enormous demand for building materials, and bricks in particular. Mr. Henry Clayton, of the Atlas Works, London, the eminent maker of brick machinery, obtained some time since special privileges from the Russian Government for the introduction of his well-known and successful machinery and his system of Brick manufacture throughout. For the establishment of very extensive brick manufactories in St. Peterburg and Moscow, Mr. Clayton has, during this month, sent out a staff of first-class men to superintend the erection of the buildings and machinery requisite for those works—one of which is to be capable of producing at least ten millions of bricks per annum.

We extract the following from the *Sun*:—"Mr. Hopley, of Eastbourne, the author of various well-known publications having for their object the physical, intellectual, and moral improvement of the country, is, it appears, about to erect in the vicinity of Eastbourne or Brighton a house which, so far as

Digitized by Google

we can judge, is likely to prove a specimen of a *Model Domestic Dwelling* for the upper and the wealthy middle classes. In it he 'is desirous that there should be manifested the most advanced principles of building science as applicable to health, domestic comforts, domestic economy, the saving of time, labour,' &c. 'Efficiency, simplicity, and lowness of price will be conjointly considered in judging of the value of a principle;' and all engaged in the manufacture or sale of articles applied to house construction are invited to forward any circulars explanatory of new inventions, or well-approved plans for ventilation, drainage, water-supply, house-warming, bell-hanging, &c., &c., and these will receive careful attention. The best approved water-closets, traps, drain-pipes, grates, kitchen-ranges, locks, taps, &c., are all, so far as is possible, in connection with one simple dwelling-place, to have a fair trial. In fact, this is likely to prove a very valuable undertaking. No one who has noted how the *practical* abounds in all Mr. Hopley's writings, will think it likely that he will be led away by enthusiasm to attempt more than will be practically useful. He appears fully aware that to serve its intended purpose the house must be a model of *cheapness* as well as of everything else that is good. Strength and durability are to be kept constantly in view. The style to be aimed at is a chaste but elegant simplicity. Taste is to be studied everywhere; but no unnecessary shilling is to be expended on unnecessary ornament. We augur well of this undertaking. Mr. Hopley, in his 'Essay on Respiration,' has laboured hard to bring about a better style of dwelling for the poor; and now it seems the common defects in the houses of the wealthier classes are to be practically pointed out. What these defects are, most people are pretty well aware of—smokey chimneys, comfortless and most unphilosophical grates, ill-ventilated and low-pitched bed-rooms, especially for the servants; wall-papers exhibiting colours which are known to the scientific world as giving forth matters of a deleterious and often of a highly poisonous character; bell-wires that are constantly wanting mending; drains that are constantly wanting cleansing; ceilings that are constantly cracking—and so on. He who shows by an assemblage, at a reasonable rate, of all the domestic building proprieties under one roof, or upon one building plot, that such common disagreeables are quite unnecessary, will be doing, we take it, no mean thing for the domestic comfort of England. We believe we cannot wish Mr. Hopley any greater reward for his endeavours in this direction than that he may live to see many houses similar to that which he proposes to build spring up in his own immediate neighbourhood and throughout the country."

The engagement of the host of performers for the Great Handel Festival at the Crystal Palace has now been completed by the Sacred Harmonic Society. The extent of the orchestra will be appreciated when it is stated that it will comprise 242 violins and violas, 120 violoncellos and double basses, with about 100 wind and other instruments, which, with 2,700 choralists—all efficient and most carefully selected—will form an aggregate considerably beyond three thousand performers. The orchestra itself is 216 feet wide, or double the diameter of the dome of St. Paul's Cathedral. It is capable of containing many hundreds more than the numbers above stated; but as it has been the express object of the managers of the festival to develop the tone produced by this gigantic assemblage of musicians under the most favourable conditions, such a liberal allowance of space has been given to each performer, and so many wide avenues intersect and divide each portion of the chorus, that it has been found absolutely imperative—despite the many thousands of efficient applicants now registered in the books kept by the Sacred Harmonic Society—to limit the performers to the number above stated. Arrangements are now in progress at the Crystal Palace for the exhibition of various relics and memorials of Handel, in a court arranged for the purpose. This collection gives promise of great interest. The wide-spread interest excited has led the directors to apply to the Commander-in-Chief to give facilities to officers in the army for attending the festival; and an official intimation has been given that, on application, leave of absence will be given for the festival week to such officers as may desire to be present. Steps have also been taken for affording the opportunity for attending the festival to members of the provincial press. The telegraphic arrangements being made on the present occasion will offer increased facilities over those in 1857.

PATENT FILE-CUTTING MACHINE.—We visited a few days ago the mechanical establishment of Messrs. Greenwood and Batley, of this town, for the purpose of inspecting a patent file-cutting machine recently imported from France. This machine is exceedingly ingenious, and does great credit to the inventor, for it has long been a desideratum to cut files by machinery, which object seems now to be completely attained. The file is placed upon a self-adjusting bed, capable of being turned in any direction, and the chisel or cutting instrument is fixed in a vertical slide, actuated by a spring and a carn, and giving about a thousand blows per minute. The machine is perfectly under the control of the workman, and occupies very little room; it produces better files than can be made by hand labour, and will do ten or twelve times as much work as an ordinary skilled workman. The machine is already in operation in France and Belgium; in the former country nearly half a million of files can be annually produced at the patent file manufactory. We understand it is intended to establish a Joint Stock Company to carry out at Leeds the manufacture of files by this process on an extensive scale. This would add another very important branch of trade to our town, and afford an additional supply of work to its industrious artizans. We therefore wish the promoters every success in their undertaking. *Leeds Mercury.*

Patents for Inventions.

PROVISIONAL PROTECTIONS.

Dated March 31, 1859.

808. D. B. White, of Newcastle-on-Tyne, Doctor of Medicine. An improved indicating guage-lead or plummet.

Dated April 23, 1859.

1012. H. Keach and G. H. Farrington, of Bush-lane, Wholesale Stationers. Improved advertising circulars.

Dated May 12, 1859.

1189. D. Foxwell, of Manchester, Card Manufacturer. Improvements in sewing machines and apparatus connected therewith.

1193. T. R. Oswald, of Sunderland, Ship Builder. Improvements in building ships and other vessels.

Dated May 13, 1859.

1195. J. Woodley, of Limehouse, Cooper. Improvements in sawing machines.

1197. W. Clark, of Chancery-lane. Certain improvements in knitting machines. A communication from J. B. Aiken.

1199. W. Whitehouse, of New Ferry, near Birkenhead, Gentleman. Improvements in steam vessels.

1201. T. Vicars, sen., T. Vicars, jun., and T. Ashmore, of Liverpool, Engineers, and J. Smith, of the same place, Baker. Improvements in the manufacture of bread, biscuits, and like articles, and in the machinery and apparatus connected therewith.

1203. J. H. Johnson, of Lincoln's-inn-fields. Improvements in machinery or apparatus for treating india-rubber and other similar gums. A communication from A. G. Day.

1205. J. T. Beale, of Greenwich, Engineer, and T. N. Kirkham, of Upper Halliford, Civil Engineer. Improvements in the preparation of colours for dyeing and printing.

Dated May 14, 1859.

1207. J. M. Munro, of Bristol, Agricultural Implement Manufacturer. Improvements in the manufacture and arrangements of chain harrows.

1209. W. E. Gedge, of Wellington-st., Strand. Improvements in dyeing. A communication from J. B. Thénault.

1211. T. Cooper, of West Bromwich, Builder, and T. J. Evans, of West Bromwich, Manager. A new or improved oven or stove for baking, for drying japanned and lacquered goods, and for such other purposes as the same is or may be applicable to.

1213. J. Chatterton, of Islington. Improvements in covering wires and other metal conductors for telegraphic purposes.

Dated May 16, 1859.

1215. E. Adams, of the Stanton Iron Works, Derby, Furnace Manager. The employment of machinery for drawing or extracting the gas flame or smoke from furnaces, and forcing the same into them, or into the cupola, to be used as blast or fuel for melting iron or mines of any description.

1217. J. Jones, of Dorstone, Hereford, Gentleman. Improvements in musical instruments.

1219. G. Allcraft, of Upper Thames-st. Improvements in pressure guages. A communication from J. Allcraft.

1221. W. E. Newton, of Chancery-lane. Improvements in manufacturing instruments for sharpening knives. A communication from C. S. Pomeroy.

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

1249. G. R. Sampson, of Massachusetts. A new and useful improvement in propelling navigable vessels through water. A communication from J. Taggart. Dated May 20, 1859.

1259. E. Pasquier, Mechanic, of Reims, France. Apparatus for drying wool, and all filaceous matters. Dated May 23, 1859.

1286. M. A. F. Mennons, of Paris. An improved apparatus for the preparation of sand moulds for metal casting. A communication from Maudoy and Couty. Dated May 24, 1859.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(*From the London Gazette, May* 31, 1859.)

152. R. A. Brooman. Silk thread. A communication.
160. P. A. Sparre. Paper.
176. S. Phillips. Sliding sashes, &c.
179. J. Bent. Clasps.
185. L. Le Prince. Boots and shoes.
187. G. Ellis. Muffs.
189. R. Howell and R. J. Wilder. Taps.
198. B. Lauth. Rolling plates, &c.
199. J. Edwards. Buckles.
206. T. W. Rammell. Atmospheric propulsion.
210. R. Mushet. Cast steel and iron.
211. R. Mushet. Cast steel.
212. R. A. Brooman. Pumps. A communication.
213. J. Laubereau. Air engines.
226. W. and H. Hodgson. Spinning.
236. I. Hammond. Fire-arms and cartridges.
240. F. C. C. Paulsen and A. Alsing. Beverages.
254. J. Gathercole. Envelopes and paper bags.
270. J. J. A. de Bronac and A. J. M. Decherrypon. Treating metallic sulphurets, &c.
281. L. Regolieu. Brake for carriages.
294. E. H. Bentall. Grinding or pulverizing.
320. R. A. Brooman. Cooling beer. A communication.
372. W. E. Newton. Fire-arms and cartridges. A communication.
497. G. Turnbull. Permanent way.
603. G. Twigg. Fusee-igniter.
676. R. A. Brooman. Treating barley. A communication.
731. R. A. Brooman. Fire-arms, ordnance, and projectiles. A communication.
766. G. Naylor. Apparatus for measuring distance.
844. M. A. Crooker. Paddle-wheels.
896. H. F. Gardner. Boots and shoes. Partly a communication.
910. W. Clark. Lowering ships' boats.
926. R. Coleman. Agricultural implements.
934. J. Gillett. Mill.
1043. H. Allman. Window-blind mountings.
1083. J. Toussaint. Modelling and moulding.
1090. C. H. G. Williams. Colouring matters.
1124. J. Scholfield and W. Cudworth. Spinning.
1153. R. Pearsall. Glass shades.
1155. R. D. Kay. Colouring matters. A communication.
1167. W. F. Nuthall. Ordnance, fire-arms and projectiles.
1203. J. H. Johnson. India-rubber. A communication.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed May 27, 1859.

2696. J. Ramsbottom.
2704. S. Diggle.
2706. L. A. Possoz.
2707. G. Oates.
2710. G. Collier and W. Noble.
2712. G. Hadfield.
2713. W. Parsons.
2714. C. Hancock.
2716. W. A. Henry.
2729. J. Thow and T. M. Hall.
2733. J. Colyer.
2734. J. Coulson.
2740. R. Laming.
2770. H. Bevan.
2788. J. G. Arnold.
2795. F. W. Fletcher.
2831. B. Lauth.
2863. G. W. Baker.
2892. J. J. Aston.
2925. W. Spence.
3007. J. H. Johnson.
80. C. M. Kernot.
155. R. Bradley and W. Craven.
209. W. C. Homersham.
222. H. Owen.
809. S. Bateson.
819. W. E. Newton.
821. W. Tod.
849. G. Haseltine.

Sealed May 30, 1859.

2739. T. P. Purssglove.
2742. J. Samuel and J. Nicholson.
2743. E. Viney.
2744. H. Adcock.
2745. F. Warner, J. Derbyshire, and A. Mann.
2748. S. Newington.
2760. G. Spiller.
2772. R. Legg.
2777. T. Sibley.
2806. W. Burness.
2818. H. Meidinger.
2828. J. Wilson.
2833. J. Lightfoot.
2838. W. Beardmore.
2840. G. W. B. Kiallmark, and W. T. Timewell.
2842. J. B. Guthrie.
2860. E. Bow.
2873. J. Bullough.
2875. W. Clark.
2891. W. Clark.
2899. J. Aitken and J. Brooks.
2901. A. Mitchell.
2916. A. S. Beliard.
544. J. Pile.
558. J. Kershaw.

PATENTS ON WHICH THE THIRD YEAR'S STAMP DUTY HAS BEEN PAID.

1244. W. Illingworth.
1252. A. R. L. de Normandy.
1263. J. Baird.
1275. G. Bell and G. Grimes.
1283. F. L. Stott, T. Belward, and J. Findlow.
1288. W. Needham and J. Kite.
1292. H. Bessemer.
1310. E. Marsden.
1313. T. W. Willett.

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement :—

STEAM ENGINES, &c., 2363, 2387, 2388, 2392, 2397, 2398, 2403, 2407, 2418, 2421.
BOILERS AND THEIR FURNACES, 2390.
ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 2374, 2380, 2416, 2418, 2427, 2428, 2433, 2438.
SHIPS AND BOATS, including their fittings, 2378, 2418, 2435.
CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 2365, 2420, 2424.
FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, 2364, 2366, 2381.
FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 2370, 2379, 2383, 2400, 2404, 2406, 2408, 2423, 2429.
BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c., 2375, 2385, 2393.
LIGHTING, HEATING, AND VENTILATING, 2368, 2382.
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 2376, 2377, 2386, 2395, 2405, 2410, 2422, 2426, 2430, 2432.
METALS, including apparatus for their manufacture, 2397, 2402, 2417.
CHEMISTRY AND PHOTOGRAPHY, 2401, 2425.
ELECTRICAL APPARATUS, 2368, 2373, 2411, 2419, 2434, 2439.
WARFARE, 2436.
LETTER PRESS PRINTING &c, 2384, 2396.
MISCELLANEOUS, 2362, 2367, 2369, 2371, 2372, 2375, 2385, 2389, 2391, 2394, 2399, 2401, 2409, 2412, 2413, 2414, 2415, 2431, 2437, 2440, 2441.

2362. A. SHAW. *A new method or mode of raising nap on the linings of sheep skins.* Dated Oct. 22, 1858.

This consists in employing pumice stone for raising nap on the lining of sheep skins. *Patent completed.*

2363. R. WALLER. *Improvements in obtaining motive power, and in apparatus connected therewith.* Dated Oct. 22, 1858.

This consists, under one modification, in constructing the apparatus or engine with a series of magnets radiating in a circular or conical form, and in arranging the armature or keeeper also in a circular or conical form, but somewhat less in diameter than the circle of the magnets, and placed eccentric thereto. A shaft is arranged within the centre of the magnets, and an arm or cam is attached thereto. On the inner circle of the armature there is a pulley or roller, the axis of which is arranged to actuate the arm or cam on the shaft. The armature may be also arranged with a series of magnets, or the outer series may be moveable and the inner one stationary, so that the two circular series being eccentric to each other, will be so attracted as to cause the central shafts to revolve. The improvements in batteries consist in giving a current or stream to the liquid employed in the cells for cleaning and other purposes; also in working the cells or troughs under pressure greater or less than that of the atmosphere. *Patent completed.*

2364. R. KENNEDY and J. ARMSTRONG. *An improved kiln for drying grain.* Dated October 22, 1858.

This consists in arranging the tiles of the kiln in a slanting position, one over the other, across a drying chamber. The grain passes through an aperture at the top of the chamber on to the upper side of the highest inclined plane. The grain passes down this first plane to the opposite side of the chamber, where in passing to the next inclined surface—which is inclined in an opposite direction—the grain is turned over by means of a curve. This process of turning the grain from one plane to the other has the effect of reversing the surface of the grain that has been in contact with the heated tiles, and the reversing of the grain is continued as often as required until the grain be properly dried. The flow of the grain downwards is regulated by a cylinder or wheel placed at the lower side of the undermost inclined surface. The velocity of this cylinder or wheel is regulated by clockwork. The inclined surfaces are supplied underneath with heated air. There are other modifications included. *Patent completed.*

2365. C. CLAY. *Improvements in apparatus for harrowing, scarifying, and cultivating land.* Dated Oct. 22, 1858.

Here a frame is employed, to which is fixed bars having tines secured to them, the stem of the tine being bent or curved round the bar, so as, supposing the bar to be square in section, to fit to three of its sides; or if the bar be of any other form, the stem of the tine is bent round it to a similar extent. Through the stem of the tine two key-ways are cut, one opposite to the other, in such a position that a key pushed through them comes against the fourth or remaining side of the bar, thus fixing the tine very firmly in its place, and allowing of its being readily removed. The implement may be drawn by horses; and the depth to which the tines penetrate the land may be regulated by adjustable wheels. There are various modifications included. *Patent completed.*

2366. E. PALMER and E. PALMER. *Improvements in machinery or apparatus for cutting hay, straw, or other similar substances.* Dated October 23, 1858.

This consists of a shaft supported and revolving in bearings, and carrying, by means of arms or otherwise, two or more blades or cutters having their length running in a direction parallel to that of the axis, and their width more or less approaching the direction of their circle of revolution. These blades or cutters are tapered off so as to form cutting edges in the direction of their length, and are adjustable by suitable screws, so that as they are carried round by the revolution of the axis they successively pass, and may to some extent rub against a blade or "ledger plate" placed in an inclined position with regard to the axis and revolving blades before named, and serving as a fixed cutter between which and the revolving blades the hay or other substance to be operated upon is cut. It will thus be seen that the moveable blades successively act with the "ledger plate" in the manner of which one blade (the "ledger plate) is fixed, and the other is attached, its edge forming a suitable cutting angle with that of the fixed blade, by arms or otherwise, to an axis whereby it is carried downward past the fixed blade. The "ledger plate" or fixed blade is situated at the end of a suitable trough or guide casing into which the material to be cut is fed, and along which it is drawn gradually forward by toothed rollers to the "ledger plate" to be cut as described. Motion is given to the parts by a toothed wheel revolving horizontally upon or with a vertical shaft or spindle, and of sufficient size to allow one or more horses to be yoked thereto. *Patent completed.*

2367. P. C. STORTZ. *An improvement for taking life-size pictures from smaller pictures either with or without the aid of photography.* Dated October 23, 1858.

Here the inventor places a double or single lens with a camera so that the lens is turned in a dark room a transparent positive or negative image against the daylight. In the dark room is placed on an easel a card, board, canvas, glass, or paper on which will be seen the image on a large scale. If the image is negative the inventor takes indian ink or any colour pencil or chalk and fills up all white lines and designs which, when seen in daylight, will produce an exact image of the smaller one. If it appears positive on the canvas he takes the same ink or colour but does only the outlines, which will produce the same effect; or in rendering the surface of the said card, board, canvas, glass, or paper sensitive to light an image by photographic means may be produced of life or any other size. *Patent abandoned.*

2368. E. C. SHEPARD. *Improvements in electric lamps.* (A communication.) Dated October 23, 1858.

This consists in the employment in an electric lamp of an open seat contained in a stationary bridge plate and receiving the electrode so as to allow the point only thereof to protrude through it the distance required, and permitting the advance of the said electrode so fast only as it is oxydized and reduced by the electric current. And also in the combination of a loaded tube carrying the upper electrode, an open seat, and a mercury tube, in which floats and is secured the lower electrode, so that while the upper tube feeds the upper electrode down to the open seat as fast as it is reduced, the lower electrode is also fed up as fast as reduced, and keeps in its proper position with reference to the upper electrode. *Patent completed.*

2369. R. BODMER. *An improved toy or plaything for children.* (A communication.) Dated October 23, 1858.

This consists in puppets being supported by or suspended from lengths of white horse-hair or bristle, each somewhat exceeding the length of the moveable legs of the puppet, and placed on an elastic surface or platform to which a vibrating movement is imparted by a simple mechanism put into action by hand or by clockwork. *Patent completed.*

2370. G. DAVIES. *Improvements in weaving.* (A communication.) Dated October 23, 1858.

This relates to weaving articles of a circular or elliptic form without a seam. The principal feature consists in weaving such fabrics with two circular or elliptical lists or selvages, either parallel, concentric, or otherwise, the weft threads passing in a radial direction. To effect this, the width of the warp is divided into several separate breadths each independent and distinct from the other, and wound upon beams or rollers weighted in a different manner, those composing the inner circle being weighted the heaviest. The reed is parallel to the warp beams, and the cloth roller is formed of a truncated cone corresponding with the form of the article to be woven. *Patent abandoned.*

2371. J. C. MARTIN. *An improvement in the manufacture of metal moulds for moulding plastic substances.* Dated October 23, 1858.

This consists in making moulds composed of electrotype copper strengthened by the addition of other metal to render them sufficiently strong to bear the necessary pressure for producing the moulded articles. *Patent abandoned.*

2372. W. E. NEWTON. *Improvements in pumps.* (A communication.) Dated October 23, 1858.

Here the ordinary clack-valves are dispensed with, and a peculiar contrivance adapted for admitting and discharging the liquid or fluid into and from the body or cylinder of the pump. This contrivance receives an independent motion from the external mechanism. The contrivance is a two-way cock, and it operates in a similar way to the slide or throttle valve of a steam-engine, and to which it is analogous, having two passages cast in it, and communicating with the interior of the cylinder and the exit pipe or cock. *Patent completed.*

2373. W. E. NEWTON. *Improvements in telegraphic apparatus.* (A communication.) Dated Oct. 23, 1858.

This consists in sending and receiving messages simultaneously over the same wire by an accessory magnet and an accessory battery to each instrument in combination with the main batteries and main magnets, and with a means of reversing the direction of the current of each of the main batteries. The apparatus consists of two parts, the key or transmitting apparatus, and the relay or receiving apparatus. The transmitting key also serves to reverse the direction of the current, and may therefore be called a reversing key. The invention further relates to a means of printing despatches as received. This feature is not described apart from the drawings. *Patent completed.*

2374. E. COTTAM. *Improvements in the internal fittings of carriages.* Dated October 25, 1858.

This relates to the seats, backs, and elbow-rests of carriages (particularly railway carriages), and consists, 1, in the substitution of a combination of metallic springs, laths, and covers for the ordinary seats and backs. It consists, 2, in an arm or elbow-rest, so constructed as to turn up or down, so that the seat may be made into a couch. *Patent abandoned.*

2375. M. MASON. *Improvements in elevating stands or stages for the use of firemen in extinguishing fires; also for decorating windows, public buildings, and other purposes.* Dated October 25, 1858.

The inventor mounts a stage, about 15 feet high, upon a framework carried by four wheels, and supported at the corners by four pillars. Through the centre of the stage he passes an upright tube with a rack attached to its side along its whole length, this rack being driven by a winch on the stage. The vertical rack is arranged in lengths of about five feet long, and a circular hole is left in the bottom frame for a man to stand in, so as to allow these lengths to be inserted below, and the rack can thus be raised to any extent. On the top of the rack or stand a cage is fixed, which is railed round, and in which the fireman is placed. The bottom frame is to be weighted to give the structure the required stability. A rope is attached to each of the four corners of the cage and so arranged as to steady the rack during the ascent, and serving the same purpose to the rack as the shrouds of a ship do to the masts. *Patent abandoned.*

2376. J. J. WELCH and J. S. MARGETSON. *Improvements in the manufacture of scarfs for gentlemen's wear.* Dated October 25, 1858.

This consists in weaving gentlemen's scarfs with the ends stiffer and stouter than the part which encircles the neck. This is effected by changing the shuttle in the process of weaving. *Patent completed.*

2377. F. FOWKE. *Improvements in umbrellas and parasols.* Dated October 25, 1858.

This consists in constructing the stick of metal and with recesses which receive the stretchers and ribs. *Patent completed.*

2378. J. ROBB. *Improvements in propellers for ships and boats.* Dated October 25, 1858.

This consists of a horizontal shaft or bar, having a reciprocating motion imparted to it in the direction of its longitudinal axis. To the outer end of this shaft or bar is secured or formed a V-shaped block of metal, having the narrow end towards the ship. To this narrow end is hinged on each side a vertical wing or float, which wings are free to open out at right angles to the propeller, bar, or shafts, or to close against the sides of the piece before referred to, which latter keeps them just sufficiently open to cause them to expand when urged against the water. A transverse cross-bar or stop fitted to the propeller, shaft, or bar behind the wings serves as a rest or stop for the wings to bear against when open for being pushed through the water. The action of this propeller is consequently perfectly direct upon the body-water, the wings opening and closing as the propeller, shaft, or bar moves outwards from or inwards towards the ship. These propellors may be applied either to bow, stern, or sides of a ship. *Patent completed.*

2379. T. and J. ASHWORTH. *Certain improvements in power-looms for weaving.* Dated October 25, 1858.

This relates, 1, to apparatus for actuating the picking rods of power-looms for weaving patterns, and consists in the use of a single endless pattern chain, by which a greater number of single picks of various colours or thread can be given than hitherto. It relates, 2, to the healds, and consists in a novel method and arrangement of apparatus for raising and lowering the healds simultaneously. *Patent completed.*

2380. W. CRADDOCK and J. WHITE. *Improvements in the connecting links of harness hames.* Dated October 25, 1858.

This consists in forming the connecting links of harness hames with a hook at each end, whereby they are hooked into the eyes of the hames, instead of the hames being introduced into the body of the link as usual. *Patent completed.*

2381. G. KENT. *An improved churn.* (A communication.) Dated October 25, 1858.

This consists of an arrangement of parts, including the use of certain pipes for drawing air down continuously into the liquid as the churn is rotated, and is not described apart from the drawings. *Patent completed.*

2382. A. V. NEWTON. *An improvement in the manufacture of candles.* (A communication.) Dated Oct. 25, 1858.

This consists in coating candles made of tallow, &c., with a plurality of compositions formed of stearic acid and tallow in varying proportions, together with proper wicks to give different degrees of fusibility, and also of flame

Digitized by Google

degrees of hardness and smoothness to the same, in connection with an increased illuminating power. *Patent completed.*

2383. S. R. PARKHURST. *Improvements in cotton gins.* Dated October 25, 1858.

This consists in connecting the stripper and ginning cylinder with an internal gear, viz., a female wheel gear surrounding and driving the pinion on the end of the stripper shaft, by which several advantages are secured. *Patent completed.*

2384. M. MASON. *Improvements in self-acting feeding machines or apparatus for all descriptions of steam or other letter-press printing machines or presses.* Dated October 26, 1858.

This includes a combination of parts for effecting the purposes of the invention, which the inventor in his specification describes in detail, but for which we cannot afford space. *Patent abandoned.*

2385. A. V. NEWTON. *Improved machinery for pulverising, kneading, pressing, and moulding clay and other plastic materials.* (A communication.) Dated October 26, 1858.

This consists, 1, in pulverising, kneading, and forcing the clay, &c., into the moulds. 2. In preventing the lateral oozing of the clay, &c., during its passage through the machine. 3. In the use of adjustable triangular concave base walls or guides, arranged in such relative manner to the rollers as to afford a kneading recess, and to act as cleaners to the rollers between which they are arranged. 4. In dies or moulds formed to act as scrapers and cleaners to the rollers from which they receive the kneaded and compressed material as it is forced through the machine, and mould the same for architectural or mechanical purposes. 5. In severing the plastic material at desired points as it is forced through the dies. *Patent completed.*

2386. C. WIELAND. *Certain improvements in chronometers, watches, and such like timekeepers.* Dated October 26, 1858.

Here the inventor makes the rim of the balance of one piece of metal, and to the bar and rim he connects the following parts for giving the compensating property thereto, namely, two curved pieces of two different kinds of metal connected together in the usual way, so as to combine and render useful the expanding and contracting properties of these metals. *Patent abandoned.*

2387. B. GOODFELLOW. *Certain improvements in steam-engines.* Dated October 27, 1858.

This particularly applies to horizontal condensing engines, and consists in placing the air pump between the cylinder and the crank, and in attaching the air pump piston to the piston rod of the cylinder. *Patent completed.*

2388. J. LUIS. *A new syphon water-wheel, receiving its water without destroying the water level.* (A communication.) Dated October 27, 1858.

This new system of water-wheel receives its water without destroying the level of the water. Beyond this the nature of the invention is not further explained. *Patent abandoned.*

2389. J. LUIS. *A new machine for boring.* (A communication.) Dated October 27, 1858.

This consists in the substitution of cords in the place of the boring rods hitherto used. It is not completely described apart from the drawings. *Patent completed.*

2390. J. BLEAKLEY. *Improvements in boilers, flues, and the methods of fixing the same.* Dated Oct. 27, 1858.

This consists in arranging a number of shells or boilers inserted inside each other, each one being several inches smaller in diameter than the one into which it is inserted. The shells or boilers thus arranged rest upon fixed supports, leaving a sufficient cavity for the flame or heat to traverse. The inventor places arches or tiles in the combustion chamber for igniting the smoke, so as to consume it or cause it to pass in a flame through the flues, which can be fixed either in the line of the flues or at right angles with them. *Patent abandoned.*

2391. A. P. A. BEAU. *A pocket stereoscope.* Dated October 27, 1858.

The patentee proposes to bind or attach the frame in which the two lenses are set to two covers or flaps, so as to resemble a small pocket-book or note-book. These flaps or covers are made so as to have pockets in the inside, within which may be carried writing materials, visiting cards, postage stamps, &c. *Patent completed.*

2392. J. KINSEY. *Improvements in steam-engines and pumps.* Dated October 27, 1858.

This consists in a mode of combining the plunger and barrel of a pump with a piston and piston rod of the motive power engine, by which a direct pumping action is effected, a simpler and stronger arrangement of working parts connected with the cylinder piston and piston rod gear is enabled to be made, and a reduction in the number of parts and wearing surfaces requiring attention and adjustment, and by which economy in the first cost and in wear and tear is effected. *Patent completed.*

2393. C. CHEYNE. *Improvements in the construction of floors and ceilings.* Dated October 27, 1858.

For floors only, where no ceilings are needed, such as stores and warehouses, the inventor constructs floors by iron girders with flanges, upon which are secured plates of corrugated iron, galvanised or not according to circumstances; upon these plates he places a layer or layers of concrete, mortar, cement, or other like fire-resisting material, in which are embedded rafters of wood, to which the flooring is connected. For floors and ceilings he uses perforated or stout wire-cloth for carrying the material of which the ceiling is to be formed. *Patent abandoned.*

2394. L. WRAY. *The preparation and application of a substitute for gutta-percha, caoutchouc, and similar substances.* Dated October 27, 1858.

This invention was described at page 321, No. 20, of the MECHANICS' MAGAZINE (New Series). *Patent abandoned.*

2395. G. SPEIGHT. *Improved plaits and curls or ringlets for head dresses or ornaments or additions to the natural hair, and an improved apparatus for the manufacture of curls or ringlets.* Dated October 27, 1858.

This invention was described at page 321, No. 20, of the MECHANICS' MAGAZINE (New Series). *Patent completed.*

2396. M. MASON. *Improvements in letter-press printing machines.* Dated October 27, 1858.

Here the paper to supply the machine is rolled in one continuous length or web around a cylinder. It then passes into the machine, and is printed on its upper side, the printing cylinder having its type arranged on its surface, and is placed above the paper. It is then carried forward a short distance to another cylinder and printed on the reverse or under side, the printing cylinder being placed below it. On emerging from the machine it is passed on to a sloping form, and when the proper length has been carried through, the paper is severed by a pair of shears, operated by a lever which is struck by a catch placed in a proper position on the periphery of the lower printing cylinder. This description of printing machine is self-feeding, the paper being fed in one continuous length; the two printing cylinders are connected together by bevil gearing, and all the other cylinders and rollers also being connected together, they operate simultaneously. It is also supplied with tapes in the usual manner for carrying forward the paper in its proper course through the printing machine. *Patent abandoned.*

2397. P. G. GARDINER. *Furnaces for reheating steel, preparatory to hardening, tempering, or annealing.* Dated October 27, 1858.

This consists in so arranging the furnace as to cause the flame and heat to act upon a closed oven in which the metal is placed, so as to distribute the heat under, above, and on the back of the oven, and to communicate a powerful and steady heat to the interior of the oven, while such interior and its contents have no communication with the flame or gases of combustion, and as little as possible with the external atmosphere. *Patent abandoned.*

2398. T. ALMOND. *Improvements in furnaces for the better combustion of smoke.* Dated October 27, 1858.

Here the patentee places a partition in the fire-box which partially divides the front part from the part next the tubes. In locomotive boilers this partition is formed of a water-space, having through-holes or smoke-channels, space and passage being provided from the fire over the top, and it may be also underneath this partition. He prefers to place this partition at an incline, so as to be nearly in a line with the angles of the fire-box. On the side of this partition, next the tube, he places a number of hollow fire-tubes, which lie with the hollow side against the water partition; and, being made in short lengths, are placed one above the other to form continuous channels from the lower to the upper part of the partition. These channels conduct the products of combustion passing below the partition and through the tubes or passages in it before mentioned. A series of such inclined channels are formed throughout the breadth of the fire-box, so as to receive the products of combustion all the way across. Immediately on these fire-clay flues or channels is laid a second series of tubes of like construction, which form also a series of channels abutting and resting against the flue channels. These latter are for the passage of air admitted from the exterior through the fire-box at a point under the body of the boiler or at other suitable position. The air inlets have slides to regulate the supply of air admitted. The air, in passing up through the fire-tile channels becomes heated, and is emitted into the fire-box in close proximity to the products of combustion passing up through the channels before mentioned, or over the partition with which it mingles, thereby causing the combustion of the smoke. *Patent completed.*

2399. J. W. MOTT. *Improvements in pouches of india-rubber for holding tobacco or other substances.* Dated October 27, 1858.

The patentee attaches to the flap, or makes in one piece with it, an elastic band, which serves to keep the flap closed by passing from side to side of the flap behind the back of the pouch. *Patent completed.*

2400. D. VARLEY. *An improved picker for looms.* Dated October 28, 1858.

The inventor makes a metal frame with a slot for the picker stick to work in, as in the ordinary picker, and in the vertical part of the frame he makes another slot or hole, by which he fastens a piece of buffalo-hide by a screw. The piece of hide is easily removed and a fresh piece substituted. He also makes two holes in the metal frame, through which the spindle passes. *Patent abandoned.*

2401. G. M. CASENTINI and J. O. BARNARD. *A certain composition to be used in the manufacture of articles composed of, or made with plaster of Paris and other similar substances.* Dated October 28, 1858.

The patentees boil water containing a certain quantity of cream of tartar, and while in the boiling state add by degrees white boiling borax of commerce in the proportion of 1 lb. of borax for each quarter of an ounce of cream of tartar. The mixture is boiled until a thickish paste is formed, and it is finally rolled or pounded. *Patent completed.*

2402. P. G. GARDINER. *A new and useful apparatus for cooling and preserving an equable and low temperature in the oil or composition, or other fluid mixture used for the purposes of tempering, annealing, or hardening steel.* Dated October 28, 1858.

This consists chiefly of two large iron cylindrical tanks placed side by side at a short distance from each other, upon a platform, and in a suitable framing of timber. The two tanks are connected by a pipe near the bottom. Within each of these tanks is placed a worm or coil of metal pipe, through which water is made to circulate for keeping the oil cool. A sufficient space is left at the centre of the coils in the tank for a well, in which the springs or metal may be plunged and withdrawn, without interfering with the coils. These tanks have moveable covers perforated with small holes, and the cover of one of them, which is the immersion-tank, has a circular opening at the centre large enough to admit the springs or pieces of steel with facility. The small holes in the cover act as strainers for the oil from the springs or pieces of steel placed upon them. Over and upon the central part of the other tank there is a metallic cylindrical chamber, within which is placed a central tube and a series of horizontal perforated discs. In connection with this chamber is a pumping apparatus, whereby the heated oil is drawn from the immersion-tank through a pipe and delivered on to the perforated discs of the upper chamber, from which it descends in a shower, and is cooled by currents of air. The cooled oil runs through the perforated cover of the tank below into the said tank, and from thence into the immersion-tank. A perfect circulation of the oil is thus kept up. *Patent abandoned.*

2403. J. WESTERBY. *An improved application of steam vessels filled with oil, tallow, or other materials for lubricating the cylinders of steam engines of high or low pressure.* Dated October 28, 1858.

This consists in the introduction of steam from the steam chest or valve-box, or from the steam pipe or boiler, into the grease-cup attached to the cylinder above the surface of the lubricating matter. The object is to force the lubricating material into the cylinder whatever the pressure of steam in the cylinder. *Patent completed.*

2404. C. POOLEY. *Certain improvements in, and applicable to, carding engines, and other machines for preparing cotton and other fibrous materials.* Dated October 28, 1858.

This relates, 1, to those carding engines in which workers and clearing rollers are employed, and consists in a mode of making and applying covers to the bearings of such rollers, these covers being attached to the main cover of the rollers. It consists, 2, in fixing rods above the line of carding engines, and in suspending hooks to the said rods for holding up the covers of the workers and clearers. It relates, 3, to the drawing rollers of carding engines, drawing frames, &c., and consists in applying to the top rollers revolving clearers furnished with a friction apparatus to retard their rotary motion. It consists, 4, of a machine for unwinding the last layer of rovings from the bobbins or spools of roving or slubbing frames. The bobbin or spool from which the layer of rovings is to be unwound, is placed between two rollers which are nearly in contact, and which are made to revolve rapidly, and the roving is thereby unwound. *Patent completed.*

2405. T. RAILTON. *Improvements in the apparatus employed in the manufacture of cap or bonnet fronts.* Dated October 28, 1858.

This relates to the hinged parallel holders used for making cap fronts, &c., and consists, 1, in making the holders of such a shape that the centre of the front is lower than the two extremities, the first gradually increasing in width. 2. In making one of the holders with a hinged division at each end, and so that the cap front, &c., may be made with three sides. *Patent completed.*

2406. A HEYWOOD. *Improvements in machinery or apparatus for suspending paper and woven fabrics to be dried.* (A communication.) Dated October 28, 1858.

When the paper, &c., leaves the grounding, staining, or other machine, it is taken over a revolving roller, which guides it to a pair of diagonal endless straps with hooks or pegs, to carry forward the lags or rods over which the paper, &c., passes. These lags or rods, with the paper, &c., suspended in loops from them, are deposited by the diagonal endless straps on to a pair of endless belts or ropes, which move horizontally, and gradually convey the loops of paper, &c., along the drying chamber in which they are suspended. The lags or rods are selected from a receptacle by a pair of hooks attached to the diagonal straps. *Patent completed.*

2407. J. EVANS. *Improvements in lubricating the slide valves and pistons of steam engines, and in apparatus for this purpose.* Dated October 28, 1858.

This consists in supplying lubricating matter to the face on which the valve works, and also to the interior of the cylinder, by mounting a lubricating cap on the casing of the slide valve, so that the lubricating matter may pass direct to the valve, and also with the steam into the interior of the cylinder. The inventor uses a cup with a cover, and with one tap only. *Patent abandoned.*

2408. B. FOSTER and P. SMITH. *Improvements in machinery or apparatus for spinning and doubling wool, alpaca, mohair, cotton, silk, flax, and other fibrous substances.* Dated October 28, 1858.

This consists in the application of a cup or bell placed upon the upper end of a spindle for conveying the material to a rotatory bobbin, which rises and falls within the cup or bell. It also relates to the wharves for such bobbins, and consists in forming one of the flanges larger than the other, to enable the attendant to stop it by applying a knee. *Patent completed.*

2409. W. MUNRO. *A new manufacture of capsules and other metallic articles.* Dated October 28, 1858.

Here the patentee first prepares a sulphate of tin by placing 1 lb. of tin cut into thin strips in a bottle containing two quarts of water; to this he adds 3 lbs of muriatic acid. He then filters the same through Dutch filtering paper into a vessel capable of holding five gallons of water. When the solution of tin is filtered, he adds to it as much soft water as will make, when mixed, three gallons of the solution. He then dissolves 28 ounces of common soda in 2 gallons of warm water, and pours it gently into the tin solution, when a white carbonate of tin will be precipitated. He then empties the vessel and washes the carbonate of tin in water and filters it through cotton, so that it becomes a thick paste, which he returns to the vessel previously used and emptied, and by mixing with it three gallons of water he brings the solution of tin into a fine cream-like condition. He then takes two pounds of sulphuric acid, diluted in two gallons of water, and stirs the same into the previously prepared solution of tin, and thus a sulphate of tin will be produced. Having obtained the sulphate of tin he then places so much as may be required of it in a trough of wood or stone of a galvanic battery. He then takes pieces of the same size of the tin and of the lead, well cleaned on the surface, and places them in the trough

Digitized by Google

face to face, the tin to be on the copper wire and the lead on the zinc wire of the galvanic battery, by which means and by the action of the galvanic battery—using to create the force one part of sulphuric acid to fourteen parts of water—the lead will become coated with tin to any thickness required, and the combined metal may then be rolled down to a suitable thinness by ordinary flattening rollers or other suitable means. The sheets so produced may then be made into capsules, &c. *Patent completed.*

2410. J. SMITH. *Improved hats and coverings for the head.* Dated October 28, 1858.

This consists in the adaptation to hats, &c., of the crinoline material described in the specification of a former patent, No. 2669, dated 22nd Oct., 1857, that is to say, a material composed of horse-hair as the weft, and having a linen or flaxen chain or warp. *Patent completed.*

2411. W. HALL and A. WELLS. *Improvements in electric telegraph cables, and in machinery employed in the manufacture thereof.* Dated October 28, 1858.

This invention was described and illustrated at page 300, No. 19, of the MECHANICS' MAGAZINE (New Series). *Patent completed.*

2412. P. BRUNON. *A improved mode of manufacturing cocks.* Dated October 29, 1858.

This consists in manufacturing cocks of glass, &c., by running the material in a melted state in moulds, &c., so as to form the entire metal or body in one casting. The plug is also cast in the same way, and very little grinding is required to make the plug fit the barrel. *Patent completed.*

2413. W. KIRRAGE. *An improved elastic combination of materials impervious to atmospheric influences, as a substitute for hard woods, metal, leather, or felting, and for other purposes.* Dated October 29, 1858.

The materials constituting the new compound are india-rubber, gutta-percha, tar, and sulphur, with certain other ingredients according to the purposes for which it is required. *Patent completed.*

2414. J. DRANSFIELD. *Certain improvements in cocks, taps, or valves.* Dated October 29, 1858.

This consists in the use of a hollow plug conically formed, the apex of the cone being uppermost, and to which the handle is attached. This plug is furnished with an outlet, and has its exterior surface bearing against the interior surface or seating of the tap or valve; it will thus be evident that the pressure of water within the hollow plug will retain the plug against its seating, the flow of water being caused by turning the plug as usual by a handle or otherwise. *Patent abandoned.*

2415. P. WRIGHT. *Improvements in the manufacture of anvils.* Dated October 29, 1858.

This relates to a former patent, which consisted in making an anvil in two halves welded together; the present improvement consists in dispensing with the necessity for welding them together by shaping the parts in a manner that is not described apart from the drawings. *Patent completed.*

2416. W. E. NEWTON. *An improved method of attaching wheels to the axles of railway carriages.* (A communication.) Dated October 29, 1858.

The object here is to enable the wheels of railway carriages to turn independently, and the invention consists in attaching the wheel to its axle by an auxiliary hub, a certain groove, and certain segments connected with the wheel. Reference to the drawings is necessary for a detailed description of the invention. *Patent completed.*

2417. J. DIXON. *A method of manufacturing steel.* Dated October 29, 1858.

The inventor takes cast iron in plates of ½ or ⅜ths of an inch thick, and places them in a converting or cementing furnace, and stratifies the said plates with sand, ashes, charcoal, &c. The furnace being thus filled with stratified cast iron is subjected to heat for two or three weeks. This operation converts the cast iron directly into steel. *Patent abandoned.*

2418. J. WRIGHT. *An improved application of machinery to be used as a new motive propelling power.* (A communication.) Dated October 29, 1858.

The inventor employs a cylinder with one closed end and a piston. The portion of the cylinder between the closed end and the piston is exhausted of the air; this is effected in the first instance either by steam which is afterwards condensed, or by the valve in the corner of the piston; upon force being applied to the piston it is urged towards the open end of the cylinder in opposition to the resistance of the medium filling that end, which will be either water or air. *Patent completed.*

2419. G. ZANNI. *Improvements in arranging magneto-electric machines for medical and other purposes.* Dated October 29, 1858.

This consists in combining magneto-electric machines with maintaining springs and wheel-work, so that when they are required for use, the spring being liberated causes the armature of the machine to rotate, and so produces a succession of currents or shocks in the circuit of which the wire coils surrounding the armature form a part. *Patent completed.*

2420. R. W. CHANDLER and T. OLIVER. *Improvements in agricultural apparatuses for ploughing and otherwise operating upon land.* Dated October 29, 1858.

This relates in part to a former patent of the patentees dated 1st June, 1858, and consists, 1, in employing two wheels at the middle of the plough, and, where necessary, one at each end also, instead of three, four, or more wheels according to the specification of the former patent. 2. In employing a sceath or loose cutting wheel in advance of each of the ploughs for cutting through roots, &c., which would otherwise accumulate in front of the plough and clog it. 3. In constructing steam-ploughs with the principal features desbribed in the former patent, but with an engine employed between the sets of ploughs. 4. In connecting the draught ropes or chains to a nearly vertical lever or levers depending from a transverse stay on the lower part of the machine at the middle for drawing the ploughs down well into the ground when the strain comes upon the ropes or chains. 5. In forming double snatch and other blocks with pulleys which may be shifted from one position to another in the blocks, to accommodate the directions of the ploughing ropes to the varying positions and directions which it is desirable to give to the ploughs in ploughing fields of various forms. 6. In placing the drums for driving or hauling ploughs, &c., between the main wheels of the engine. *Patent completed.*

2421. R. A. BROOMAN. *Improvements in obtaining motive power.* (A communication.) Dated Oct. 29, 1858.

This consists in obtaining motive power to propel vessels and engines and carriages by the use of steam to act upon water or the liquid contained in a vessel divided into two compartments, and fitted with curved pipes or vanes through which the liquid is alternately driven from one compartment to the other, so as to obtain a re-active effect at or near the mouths of the curved pipes. Valves are used for regulating the admission and exit of the fluids, worked by floats rising and falling with the liquid. *Patent abandoned.*

2422. L. J. LEWIS. *Certain improvements in fastenings for ladies' dresses and other such like purposes, as also in the machinery for manufacturing the same.* Dated Oct. 29, 1858.

The object here is to prevent the voluntary disengagement of the hook and eye. The apparatus consists of a bed or table piece of cast-iron fitted to a stand of wood or iron. At the backpart of the bed bearings are formed for carrying a shaft, in either of which fast and loose pulleys are applied for giving motion to the apparatus, and a fly wheel or wheels. On this shaft are also fixed the various cams for producing the different actions and motions for supplying and cutting off the wire; as also in giving form to the said hooks or eyes made from such wire, likewise the planishing, marking, and delivering the same. *Patent completed.*

2423. J. MORRIS. *Improvements in the manufacture of rollers or cylinders for printing fabrics.* Dated October 29, 1858.

This consists in substituting for the hammering or swaging process a drawing process, by which the fitting of the interior bore of the rollers or cylinders to fac-similes of the printers' mandrils is rapidly, evenly and completely effected and with great economy of labour. *Patent completed.*

2424. J. DRUMMOND. *Improvements in reaping and mowing machines.* Dated Oct. 29, 1858.

This consists in a mode of constructing apparatus for reaping or mowing, in which the cutting, mechanism is arranged so that the cutters recede from the front part of the machine backwards in an angular or diagonal direction. Also in a mode of arranging the cutting apparatus, the gathering reel and the receiving board or platform, so that the whole or part thereof may be adjusted to any desired angle, and also admit by their vertical adjustments of a rising and falling motion in passing over uneven ground. The invention is not described apart from the drawings. *Patent completed.*

2425. J. H. JOHNSON. *Improvements in photography, and in the apparatus connected therewith.* (A communication.) Dated Oct. 29, 1858.

This relates to taking photographic birds'-eye views of portions of the earth's surface, and consists in fitting a photographic camera in a vertical position, with the lens downwards, into the bottom or side of the car of a balloon, such car being formed when requisite with a dark chamber by surrounding it at the upper part with black silk, and covering or closing the space or chamber so formed by a moveable roof or ceiling of yellow silk for obtaining the required yellow or negative light. *Patent abandoned.*

2426. R. J. CONINGSBY. *Improved apparatus for turning over the leaves of music or other books.* Dated October 30, 1858.

At the back of each leaf to be turned over is placed a small rod or finger of ivory, &c., and each of these fingers is furnished with a spring, which, when released, causes the finger to turn over the leaf. These springs are placed one above the other, and are held back by a small fork which is attached to a lever, connected at the other end by a wire or rod to a treadle. Upon depressing this treadle by the foot, the sliding fork allows the first spring to escape and turn over its leaf, and each successive depression of the treadle allows a fresh spring to escape and turn over its respective leaf, until all the springs have been released, when the apparatus will require adjusting afresh. *Patent abandoned.*

2427. E. T. HUGHES. *Improvements in machinery or apparatus to prevent railway accidents.* (A communication). Dated October 30, 1858.

This consists in placing near the crossings of the line certain projections which act upon a powerful striking or signal apparatus attached to the locomotive or guard's van. *Patent completed.*

2428. F. WRIGLEY. *An improved self-acting safety coupling for railway and other purposes.* Dated November 1, 1858.

This consists in a combination of joint links and pins so arranged as to form a complete self-acting coupling. The parts consist of two three-fold joints, &c., each joint moving on its own centre pin. These joints are attached to the ends of the draw-bars of two carriages or trucks, and may be further described as consisting of first, the outside joint or jaw attached to and forming part of the draw-bar; second, an internal double joint or pin link; and, third, the centre or coupling link, the whole being so arranged that when so placed in position, and the carriages, &c. brought together the coupling is accomplished. *Patent completed.*

2429. G. DAVIES. *Improvements in machinery for weaving velvets and other piled fabrics.* (A communication.) Dated November 1, 1858.

This relates principally to looms for weaving two pieces of velvet, &c., face to face at one operation, the pieces being connected by the pile threads, upon severing which two distinct pieces of piled fabric are produced. It consists, 1, in a peculiar combination of two cams for working the healds or harness and the pile cutter. 2. In mechanism for "letting off" the pile warp at the proper speed. 3. In mechanism for distending and raising and depressing the pile warp. 4. In arranging the knife for cutting the pile, and in means of sharpening the knife. 5. In apparatus for throwing the taking-up motion out of gear to let back the pieces of fabric. 6. In means of giving the requisite amount of tension to the fabric as it is woven. We cannot give space for a detailed description of these several features. *Patent completed.*

2430. C. VERO and J. EVERITT. *Improvements in the manufacture of hats and other coverings for the head, a part of which improvements is also applicable to the manufacture of felt.* Dated November 1, 1858.

This consists in the use of a waterproof composition, felt, woven fabric, wool, and some other materials, united according to the kind of covering it is desired to produce. *Patent completed.*

2431. H. H. and W. F. HENSON. *Improvements in the manufacture and treatment of starch for domestic purposes.* Dated November 1, 1858.

The patentees employ alkaline silicates, such as silicate of soda or of potash, or any preparation of them, either alone or in combination with farina, flour, &c., to which they add any colouring or tint, or some decolorizing substance, to the silicate. *Patent completed.*

2432. J. DOBSON and D. PEARCE. *Improvements in the manufacture of bird-cages.* Dated November 1, 1858.

This relates to the manufacture of bird-cages of glass. The patentee uses pipes, tubes, or rods of glass, plain or coloured, in place of wire. The lower part and frame are made of any required material. *Patent completed.*

2433. J. CARISS. *An improved safety switch-box and gear.* Dated November 1, 1858.

This consists in constructing a switch-box so that the lever is made to lie in a horizontal position within the cover of the box, and parallel to the line of rails, by which accidents arising from the levers standing up are prevented. *Patent completed.*

2434. E. MAYNARD. *Improvements in submarine telegraph cables.* Dated November 1, 1858.

This consists in the use of parallel cords or strings of hemp, flax, silk, &c., in connection with a twisted conductor or conductors, whereby all strain in laying the cable is taken on the strands of fibrous material, and the conductor is entirely relieved from strain; and the insulation is far more perfect than with gutta-percha, &c. *Patent completed.*

2435. C. PERLEY. *Certain improved means for disconnecting boats from the davit blocks, and effecting other like objects.* Dated Nov. 1, 1858.

This consists in a block or its equivalent attached to the article itself or to the rope or chain which sustains or regulates the movement of the boat, &c., the same being provided with a lug that receives a link to sustain the article, and the block or its equivalent is provided with a drop so fitted that the link is retained in the block, so that when the drop is raised by a very slight pull the parts will be instantly disconnected. *Patent completed.*

2436. W. PALMER. *Improvements in fire-arms.* Dated Nov. 1, 1858.

This consists in an arrangement of seers, hammer, and triggers whereby the commencement of the pull on the trigger cocks the hammer removes the piece, and then it is disconnected from the other parts and gives a pause in which to take aim, and then the continuation of the pull on the trigger disconnects a second or hair-trigger by a very easy pull which causes the hammer to fire the piece. The invention is not described apart from the drawings. *Patent completed.*

2437. L. BEAVER. *An improvement in sleeve links.* Dated Nov. 2, 1858.

This consists in the novel application or adaptation of a well-known description of spring fastening to "sleeve links," whereby they are firmly secured. *Patent abandoned.*

2438. M. A. F. MENNONS. *An improved system of railway brakes.* (A communication.) Dated Nov. 2, 1858.

The patentees claim the general construction and arrangement of a railway brake, the action of which is based on the simultaneous action of pressure to each plain surface of the wheel, which pressure is effected by couples of parallel plates, or other analogous apparatus. *Patent completed.*

2439. M. A. F. MENNONS. *An improved combination for the production of voltaic electricity, and its application as a curative agent to certain parts of the human body.* (A communication.) Dated November 2, 1858.

In his drawings the applicant shows a crown, or circlet, composed of alternate zinc and copper wires twisted together, and so arranged as to be applied directly to the head, or fitted inside any suitable head covering. He also represents a garter formed in the same way of twisted copper and zinc wire, connected at the extremities; also a hair pin formed of zinc, or iron, and copper wires twisted together. *Patent completed.*

2440. D. TOMASINI. *Improvements in respirators.* Dated November 2, 1858.

This consists in constructing respirators so that they shall, when worn, be concealed from view. When the respirator is to be worn by a man, the inventor attaches it to a false beard and moustache. When it is to be worn by a female, he covers it with a false mouth. *Patent abandoned.*

2441. N. BROUGH. *Certain improvements in buttons, and in the means of attaching them to garments, which said means are also applicable for other purposes.* Dated Nov. 2, 1858.

This consists in constructing buttons so that they can be attached to garments without sewing. The shank is formed from a disc of metal, raised into somewhat of the form of the metal portion of a percussion cap. This is done partly by raising with proper tools in a fly press, and pushing them through a hole formed through a steel plate, such hole being of a conical form at the top, tapering down to the size required. These tubes are afterwards slightly reduced in their circumference, and the head part spread out so as to produce a projecting head, this part being worked up in a button. The projecting part of the head being loose, or held, or confined between the front and back shell, constitutes the principles of the invention, for, the shank fitting freely in the back shell, through which it is passed, allows the button to freely move around the shank as on an axis, and the head of the shank being small, there is also a lateral looseness in the connection. *Patent completed.*

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, JUNE 10, 1859.

STEAM YACHTS.

WE all know the delights of yachting. We do not, of course, speak of those superficial pleasures which "snobs" affect—the donning of the guernsey and the round hat, the assumption of the sailor-like bearing, the momentary blurting out of sea-phrases, the frantic swaying upon sheet and haulyard, the gluttonous consumption of cold fowl, and the perpetual swilling of poisonous grog. These are what "yachting" means to some men—if we may call them men; but it is not what it means to us. To us, as to thousands of others, we hope it implies something far above all these unmanly gratifications. It speaks of daring contests with the powers of nature—generous competitions with the elements—struggles of tact and skill—puttings forth, in short, of some of the best faculties both of body and mind. Nor are these the only sources of delight open to the true yachtsman. An inexpressible charm attends a yacht cruise, particularly upon the open sea, or near it. There is something sublime to a well-informed and well-balanced mind in bounding over the gleaming waters, with their blue deeps far beneath you, their diamond radiance all around you, the fresh flowing breeze rolling coolly over you, and above you the bright-bending dome of heaven. To a man possessing any sense of beauty, any love of the natural world, any reverence for what is Divine in the universe, nothing can be more delightful than this. Unless, indeed, there be some peculiar sensitiveness in ourselves to the charms of sea and sky—which we care not to believe. And yet—to be frank—there may be. A very few days since, we stood upon one of the highest downs of the Isle of Wight, and had the whole silver-set island spread beneath us. At that moment none of the many things which a man may possess was more coveted by us than one of those dipping, dancing craft which would in a few hours have borne us farther through the splendours of the sea than the eye could penetrate, even from that height. The burning wreck of the unhappy Eastern Monarch, which still flamed before us above the far-off waters, with all the sense of sea-perils which such a sight engenders, could not repress the admiration felt for what we mean by "yachting." This certainly looks very much like a special leaning in its favour.

But, enjoy it and laud it as we may, it cannot be denied that yachting has its miseries as well as its enjoyments, the chief of all being, perhaps,—a calm! To lie silent on waveless water, in breathless air, under a motionless sky, far away from the port which you ardently desire to reach—that is misery indeed; misery scarcely less than that of drifting leeward in a storm with broken spars towards rocks and shoals. Both of these evils many a yachtsman has experienced. The minor evil of having to bear with light, or to contend with adverse winds, all have knowledge of. Nor is there any means of avoiding these annoyances in sailing yachts. All the time we trust to the air only for propulsion we must expect to be baffled in this way.

Fortunately, however, the introduction of steam-power has furnished us with a complete and perfect remedy for such evils; and one of our objects here is to express astonishment that our yachting nobility and gentry are not more alive to the advantages of applying auxiliary steam propellers to their vessels, and to urge the subject upon their consideration. That such propellers can be applied without in the least detracting from the sailing qualities of the vessels we most confidently assert. The boilers, engines, and fuel, if properly arranged, may be made to take the place of the ordinary ballast; while a well-constructed feathering screw may be so fitted as to lie, when out of use, wholly within the dead-wood, offering no obstruction whatever to the passage of the vessel through the water.

Those who attended the Thames yacht race which was won by the Quiver a fortnight since, must have observed a steam-yacht that hovered near the competing vessels at the commencement of the race, then rapidly hauled ahead of them and steamed away seaward, returning near to the Commodore's steamer while the Quiver rounded her, and running back to Erith and Greenwich under sail alone. The performances of this steam-yacht on that occasion afford us an excellent example of what can be done in the way of steam-yachting. Let us glance, then, for a moment at the advantages which the owner of such a craft enjoys. In the first place, he would be enabled to remain in town until nearly 10 o'clock, and then proceed to Greenwich, embark, and run down to Erith in ample time to see the start. With a sailing yacht, and the wind as it stood on the day in question, this would have been impossible. In the next place, after watching the race minutely as long as seemed desirable, it was in his power to pass ahead, run down to the open water, inhale the sea breeze under sail for an hour or two in sight of the Nore, and return to witness the second great feature of the contest, viz., the rounding of the earlier vessels. Finally, he was able to let the steam go altogether, feather the screw, and run up the river like an ordinary sailing yacht, and that without the least disadvantage in point of speed. In fact, this steam-yacht played an exceedingly pretty and creditable part under sail on that occasion. With no special suit of sails, indeed with no preparation of any kind, she made such good progress on the upward run that although the second and third of the competing yachts were very near her at starting, only one of the two hauled ahead of her before reaching Erith, and that but slightly, while she kept company throughout the journey with some of the finest and fastest craft of the Club.

Nor is the use of steam in yachts necessarily attended, as some would conjecture, by any loss of comfort to those on board. In this yacht not only is the cabin accommodation both elegant and ample, but by inclining the funnel on one side, and fitting it with a shifting top, all unpleasantness from the smoke and escape steam (the engine being high-pressure) is avoided, while the vibration resulting from the screw is almost inappreciable. This last fact is mainly the result of the employment of a particular kind of screw propeller. By the use of this screw the pitch of the blades is varied according to the speed desired, the contrivance used for the purpose being of the simplest character.

It affords us much pleasure to know that the resort to steam-yachts is at last coming into favour. In Scotland, numerous small screw craft are at present in course of construction, at Greenock and elsewhere; and many other encouraging facts of a like kind have come to our knowledge. With no desire whatever to see sailing matches abandoned, on the contrary, with a strong desire to see them maintained with greater spirit than ever, we nevertheless hope to see the adoption of auxiliary screws become all but universal throughout our Yacht Clubs.

THE STATE OF THE THAMES.

THE enemy has once more occupied London as surely as the French have occupied Milan, and with even a better prospect of remaining. Once more the Thames is in a high state of putrefaction, and has been for a fortnight past exhaling the same kind of poisons as were administered to us during the hot summer of last year. This year it has attained its foul state, Dr. Letheby tells us, a month earlier than usual, and that without any remarkable elevation in the temperature, and in despite of heavy falls of rain. We may guess, therefore, what we have to expect in July and August, and prepare to die like rats, slain by—ourselves!

Last year Dr. Letheby made a full inquiry into the state of the river. The water was examined chemically and microscopically. It was tested at high and low tides, at mid-stream and near to the shores. It was collected at many places between Isleworth and Greenwich, and the inquiry was conducted with regularity every day during the whole time that the river was foul. The general results of the investigations were, that the river was highly charged with sewage and sea-water; and that the circumstances which attended or preceded the fœtid decomposition were a remarkably hot season, a continued absence of rain, a diminution in the public water supply, a flowing up of the oceanic or tidal sea-wave to an unusual height, and the sudden discharge of very offensive sewage from the somewhat stagnant sewers by a heavy fall of rain—the discharge occurring about low tide, when, instead of its passing away to sea, it flowed upwards to the higher districts of the river, and then oscillated between the extreme ranges of the tide. This last fact was particularly observed by Captain Burstall, and this year he has noticed it again. Taking the result of 172 analyses of the water which were then made, it was evident that the putrid decomposition was kept up by the sewage acting on the sulphates, &c., of the sea-water, and that the locality or confines of the decomposition was a wave undulating between Chelsea and Greenwich. At high tide it was at the former place, at low tide at the latter. The unfortunate situation of the Houses of Parliament, nearly midway in the range of undulation, was the cause of their being exposed at all times to the fœtid exhalations from the putrid wave, which never passed away beyond them.

The inquiries which Dr. Letheby has again instituted during the last fortnight have shown a similar condition of things, for the river at London-bridge is now overcharged with sewage and sea-water. In ordinary times the proportion of soluble matter in the water of that locality at mid-stream is about 50 grains per gallon, of which nearly 30 are common salt, and from three to four organic impurity; but at present it contains about 97 grains of solid matter per gallon, of which 61 are common salt and rather more than seven are organic impurities. These are in a high state of decomposition, and are giving off ammonia with that

Digitized by Google

peculiarly offensive vapour already described. The water near to the shore is still more offensive from sewage and corrupting mud, but it does not contain so large a proportion of solid saline matter. This, compared with the mean of all the experiments made during the hot season of last summer, shows that the river is not yet charged to so high a degree as it was then; for the average proportion of solid matter in the water at London-bridge was 166 grains per gallon; at Blackfriars, 154 grains; at Hungerford, 116; at Westminster, 118; at Vauxhall, 67; at Chelsea, 84; and at other places between Chelsea and Isleworth it was from 33 to 17 grains. It may, therefore, be concluded that 17 grains per gallon is the amount of solid matter naturally contained in the upland water of the Thames; but as the stream flows downwards and gets the sewage of the metropolis and the tidal current of the ocean, it rapidly becomes charged with impurities to the extent of from 166 grains per gallon to nearly 409, of which from 14 to 24 are dissolved organic matter. The first number in each case is the average of high water in mid-stream at London-bridge, and the second at Greenwich. As it was last year, so also is it now—the water in the middle of the river is charged with the highest forms of infusorial life, but that which is near to the shore is poisonous to every living thing but vibriones and the simplest of vegetable fungi.

Unhappily there is no prospect of deliverance from the curse of this foul stream

> "Which like a vast and poisonous serpent steals
> Into the swarming city."

After all the sufferings, and all the investigations, and discussions, and warnings of last year, the only measure decided upon was to pour the pollution into the river at a lower point. The only sure and sensible remedy, that of withholding it from the river altogether, and returning it to the soil, was never seriously contemplated. Until this is done we may—and, if we can, we must—mitigate the evil; but annihilate it we never shall.

SCIENCE AND LIBERTY.

On another page we publish a brief notice of Mr. John Stuart Mill's new volume on "Liberty." To some it may appear that there exists but an extremely slight connection between the objects aimed at by the writer of that work and those which we, in the pages of this Magazine, seek to compass. But in reality the connection is very deep. It is quite true that if we limit our thoughts to those scientific details with which we have most to do, we shall not come very near to Mr. Mill's theme. But it is our prerogative to rise occasionally above these details, and contemplate the broader aspects of scientific progress. And this it is impossible to do without observing that modern science is destined to play a profound part in the mental history of the world.

Up to the present moment the popular mind is practically insensible to the influence which the study of science has exerted, is still exerting, and is yet destined to exert in this respect. And what is worse, not a few of those who are partially sensible to its influence stand timidly aloof from it, as if it were something of doubtful, not to say injurious tendency. Only this week, for example, at an anniversary meeting of a Society for the Promotion of Pure Literature—a society conceived and put in motion by most excellent and able men—not a syllable was uttered by its chief supporters in recognition of the beneficial influences of scientific studies upon the popular mind. The morbid "Life" of poor Hedley Vicars, the innocent commonplaces of "Sunday at Home," the little religious fictions of the Tract Society—all these, with others of the same stamp, were abundantly recommended; but not one volume, periodical, pamphlet, or any other publication whatever in which the truths of science are taught, had its name whispered to listening ears polite. Yet is scientific literature—if simply and purely written, as much of it is—anything less than a revelation of the Laws of God? And if it be this, may it not—nay, ought it not—be diffused with as much zeal and goodwill as any of the literary inventions of man, however well intended?

We do not desire to be suspicious, but we confess to a half-belief that many excellent men have the fault of wishing to be too good. They have such an exquisite dread of false "doctrines," that they refuse even to trust the laws of nature until they have assured themselves that they exhale no odour of what they deem heresy. And, unfortunately, as they doubtless think, these laws *do* often look a little heretical to some minds. They are not invariably instituted in accordance with the wishes and intentions of well-meaning men. They are not always conformable to the views of the benevolent people of this nation and this day, any more than they are to those of similar people in other nations and former days. Hence there is a kindly disposition on the part of some good people to suppress them—or, as the laws of nature themselves cannot be suppressed, to keep the knowledge of them from the masses. The intention is doubtless an amiable one, but it will not, let us trust, be successful. We believe the truths of science are fit food for the intellect of England; and we believe this the more earnestly because they bring with them fresh supplies of that spiritual light and liberty of which the "best men" are often the most determined enemies. And we are prepared to guard our freedom in this matter.

In the address which Sir Benjamin Brodie lately delivered to the Royal Society as its President he dwelt with much intelligence and emphasis upon this and cognate topics. With the exception of the achievements of those small communities of ancient Greece, to whose works we still refer as affording the highest standard of excellence in literature and the fine arts, and from whom has been transmitted to us that marvellous science of geometry which enabled Newton to unravel the system of the universe—with this exception, there is nothing in the history of what belongs to the advancement of knowledge so remarkable as the progress which the European nations have made in the cultivation of the physical sciences during the last two hundred years. With this fact on his mind, Sir Benjamin proceeded to say that it is not only those who are engaged in researches of this kind that must contemplate with satisfaction the results of this movement. "The moral philosopher, recognising in the desire of knowledge one of the noblest of our aspirations, will regard the extension of that desire, and the more general diffusion of knowledge, as an important means of elevating our species in the scale of intellectual beings. The unprejudiced theologian will allow that there is no better foundation for the religious sentiment than the study of natural phenomena, opening as it does to our view everywhere examples of design, and of the adaptation of means to ends, combined with mighty and benevolent intention. The philosophical statesman who, contemplating the progress of society, endeavours to explain the changes which it has undergone, and thence to anticipate the future, cannot fail to perceive that the cultivation of the physical sciences has been in these later times one of the most important instruments of civilisation; while the mere utilitarian, however little he may be capable of estimating knowledge for its own sake, must admit that it has contributed more than anything else to the comforts and conveniences, not of one order only, but of every order of the community, from those who dwell in palaces to the tenants of cottages and garrets."

So confident is this able man of the truth of this view that he would not have thought it worth while, he said, to allude to the benefits conferred by scientific knowledge at all, if it were not that they show how complete a refutation a lapse of time has afforded of the views of those short-sighted cynics, who formerly opposed or ridiculed the scientific societies, as if they were engaged in trifling pursuits of no advantage to mankind. Science, continued he, has already arrived at great results, far beyond what could have been reasonably anticipated. But the inquisitive mind, looking into the future, will find reason to believe that if we could lift up the veil by which it is concealed, we should find that there are other and still greater results reserved for those who will come after us, and which even some of those who are now among us may live long enough to witness. Astronomy has been said to be the most perfect of all the sciences; and some time since it might have been supposed that, as regards it, we had not the power of carrying our researches much further. But the observations of Lord Rosse, penetrating by means of his improved telescope into the more remote regions of space, have enabled him to determine the nature of the so-called nebulous matter, and to enter on a new order of inquiries respecting the construction of the universe. The needles which now vibrate in the magnetic observatories which have been established in different regions of the earth, have already not only made us acquainted with many important facts connected with terrestrial magnetism, but have disclosed to us some remarkable relations between the earth and the sun, of which we had no conception previously. But these magnetic observations are still in progress, and if not prematurely brought to a conclusion, it would be unreasonable to doubt that they must lead to still more important discoveries as to the operation of a force which, probably like that of gravity, pervades the universe, and places even the most distant parts of it in connection with each other. A Fellow of the Royal Society—devoting to it his time, his fortune, and his intellectual powers—is in a fair way to attain the great object of his life, in the construction of an arithmetical engine of far superior capabilities to any previously invented by himself or others; such as may not only be a lasting monument of profound mathematical knowledge, of inventive genius, and of that perseverance amid difficulties which is one of the highest attributes of genius, but may be of great use to mankind hereafter, by solving with unerring certainty problems which practically are in any other way beyond the reach of the human intellect. Analogous instances might be furnished from almost every department of knowledge. If we add to these the number of investigations of a more limited kind, each complete within itself, which every year produces, also bearing in mind how great an influence the cultivation of the physical sciences during the last century has exercised on our social system, and how much it has contributed to give to modern civilization its peculiar character, we may well ask, What may not be the effect of a continuance of the same spirit of inquiry during the century which is to come, and will not its continuance help to preserve our best liberties?

MONEY-MAKING AT THE ROYAL MINT.

No. I.

PERHAPS there is no British institution, not excepting even the Bank of England, upon which is centred more interest than upon the Royal Mint. Continuously of late years, ever since the Californian and Australian gold discoveries, in fact, has it been engaged in the production of those metallic portraits of the reigning monarch which are so pleasant to look upon, and so much to be desired, and in passing them forth for the general comfort and convenience of the public. Its interior arrangements, except to employés, and to visitors, who are few and far between, have, however, been as a "sealed book" hitherto; for although the present master of the establishment is far less favourable to exclusiveness than his predecessors were, and, as we have reason to know, is most anxious to increase the facility of admission for the public, yet the nature of the operations conducted within the mystic walls of the Mint preclude that wholesale introduction of Her Majesty's lieges which is allowed at the National Gallery and British Museum. Aware of the curiosity about money-making so naturally existing in the great commercial and trading community amongst whom we are placed, and prepared with all requisite data, it is our intention to publish in this and successive numbers of the MECHANICS' MAGAZINE such an explicit and reliable description of the "inner life" of the great coin factory on Tower Hill, as shall at once supply the want of information so unavoidably experienced, and fill a gap in the mechanical and scientific literature of the country.

It is true, there are in printed existence many ostensible accounts of the processes of the art of coining as practised at the Royal Mint, from the lofty and pretentious *tomes* of the Encyclopædia Britannica down to the lowly and modest "journals of amusement and instruction," circulating at the more humble and modest prices of 2d. or 1d. each number, but these are, to a great extent, out of date or inaccurate. Dr. Ure's dictionary gives perhaps the truest portraiture of the machinery and mechanical arrangements of the place; but minting has undergone so many transmutations since its publication that considerable emendations would now be necessary if a new edition were to be published, and one which should not mislead those who referred to it for information. Of the cheaper and lighter issues from the printing-press, which have essayed to initiate the public into the mystery of making money, it must be said that generally they have failed to convey truthful or lucid impressions of it. Effect in style and eccentricity of metaphor, rather than simplicity of language and plainness of illustration, appear to be studied, indeed, in this class of paper, and the reader consequently obtains from an harmonious jingle of words an hour's empty amusement, but no solid information; some chaff, but no grain. The appetite is now not great for this species of "light reading," and it will become less and less. We are becoming daily a more practical, a more scientific, and a more thinking people, and they who seek to be popular instructors must prove that they have something to teach, or their labour will be lost.

Briefly, and before entering upon a descriptive account of the Mint *as it is*, we may be permitted to cast a glance over its annals and history. The survey thereby obtained will not be entirely without value, for it will enable us to institute comparisons, and perhaps assist in the elucidation of our subject. It becomes the more easy to ascertain particulars of the early English mode of Minting from the fact that the labours of the Royal Mint Commission of 1849-50-51, eventuated in their publishing some interesting data regarding it. This Commission consisted of "Our Right Trusty and Well Beloved Councillor, Richard Lalor Sheil, Master and Worker of our Mint," William Cotton, Esq., Sir Edward Pine Coffin, and Colonel Forbes; and it was appointed to inquire into, and report upon "the constitution, management, and expense of the Mint." Joseph Burnley Hume, a son of the patriot and patriarch, was named secretary, and certainly the inquiry was conducted with much energy. Notoriously the main object of the Government in empowering the Commission to "inquire and report," was to arm themselves with the means of dislodging from the Royal Mint a corporate body consisting of a varying number of persons, and who had from time immemorial claimed and exercised the right of coining the monies of the realm, at a heavy cost to the country, and with much profit to themselves. This body, known as the Company of Moneyers, was not, as may be imagined, very willing to relinquish its privileges, and the appointment of so great a legal authority as Mr. Sheil to a situation which did not call for the exercise of legal knowledge, proves that the Ministry foresaw a struggle with the worshipful corporation. It may be stated, without further detail, that the ancient "right"—as it was deemed of the company—to coin money, was completely set aside by the Sheil-Hume Commission in 1851, and at the close of that year the Company of Moneyers received notice of the final termination of their money-making contract with the Queen. Pensions of no inconsiderable magnitude were then given them for loss of office and prospects, and the exclusive management of the Mint devolved upon the Government. Mr. Sheil, it may be remembered, obtained soon after this *coup de loi*, a more lucrative appointment, that of ambassador to the Court of Florence, which, however, the cold hand of death caused him speedily to relinquish.

The musty parchments of the British Museum, and antiquarian *reliques* of every kind which would throw light on the origin of the Company of Moneyers—said by themselves to date from the Saxon Heptarchy—were ransacked by Mr. Hume, and much historic lore of interest did he gather by his labours. To him, indeed, we are indebted for some of the facts which follow, as to the babyhood of Minting in England. In the early Saxon and Norman periods there existed in England a variety of mints, in a variety of places, and belonging to different persons, and sometimes distinct mints in the same place. In some cases these came under the direct control of the King, in others of prelates, or some favoured subjects. These petty mints were worked by a single master, who, with sundry journeymen coiners, conducted the simple process of minting then practised, and this man was held responsible for the genuineness of the coin issued from his mint. The mints were portable, and each monarch, or prelate, in making progresses through the country, took his mint and his money-makers in his train, as necessary and useful travelling companions. It is needless to say that the hammer was the coining press of those days. The metal was first cast, then beaten to the thickness required, as nearly as the rough means employed would allow, then punched by force of hammer, and afterwards received its impressions, when laid on the face of one die from another die held upon it, and struck *à la* blacksmith, with a hammer. In short, the hammer constituted the principal implement for coining in the times referred to.

At the close of the 12th century a partial consolidation of the Royal Mints took place. At the commencement of the 13th some amended processes in the manufacture of coin were introduced, and a division of the offices took place. Henceforth we read of Workers and Minters. In the year 1279 all the Royal Mints were consolidated under one Mint-master, and he a Frenchman, Turnemire, of Marseilles. This person undertook, by special contract with the King, to execute and to be responsible for the genuineness of the coin, at a certain rate or sum for every pound of bullion coined.

In A.D. 1309 the first charter of exemption from certain taxes was granted to the Minters or Moneyers, and from this date there is little doubt the Company of Moneyers looked upon themselves as especially privileged to coin money. About the year 1465 an amalgamation of Mint journeymen workers and minters took place, and henceforth they constituted one body of "Moneyers."

In the reign of Henry VII., 1486-1509, sovereigns, shillings, and sixpences were introduced, and some minor changes were made in the management of the Mint.

Between the years 1561 and 1578 the "Mill and Screw" processes, a vast mechanical stride, as then considered, were adopted, and these were practised in the Tower of London, which now comprised the concentrated mints of the kingdom. In 1662 the improved machinery of Blondeau was tried, and after much opposition on the part of the Minters succeeded well. From this date forward modifications and improvements of machinery took place under the masterships of Sir Isaac Newton and others, but up to 1810, the rolling mills of the Tower Mint were worked by the power of horses. In the meantime, 1788, Messrs. Boulton and Watt, of Soho, had established their Royal Copper Mint, and had made numerous and extensive alterations in the *modus operandi* of coining. The Government of the day had witnessed the astounding rapidity at which the Soho Mint machinery worked as compared with their own rude appliances for striking money, and observing also the growing demand for coin, determined, in 1806, to commission Boulton and Watt to construct the machinery for a new establishment in London. Property was bought in the neighbourhood of the Tower, at a cost of £7,000, and a site thus obtained for the new Mint. Smirke gave the design for the present noble edifice which, although partly eclipsed by the national school of St. Botolph Aldgate, the first Protestant national school erected in England, presents an imposing frontage to the time-honoured fortress, and is near to St Katharine's Docks.

The steam engines for the establishment, consisting of one of 30, another of 16, and a third of 10-horse power, with the presses, were erected by Boulton and Watt; the rolling mills were the work of the celebrated John Rennie.

In 1810, and at an expense of about a quarter of a million sterling, the existing Royal Mint of England was completed, and the first coinage—one of pence—took place therein. The Company of Moneyers were the workers of the place; and, since their rates of payment remained nearly the same as when the Mint was comprised within the Tower of London, and its productive power was very small, it may be imagined that they reaped an abundant harvest. During the recoinage of silver in 1816, some account of which has been given in our pages, their profits were very large; and again, in 1843-44, the years of the light gold excitement, the Company, no doubt, did well. Better still had they fared, had they survived—as a body corporate and privileged—the great coinages of gold consequent upon the arrival of the shoals of nuggets from Australia and California. As we have said, they compulsorily retired from their lucrative positions in 1851, and great savings have resulted to the National Treasury from their departure. From 1851 to 1855, Sir John Herschel was Master of the Mint, but we are not aware that any startling improvements were made during that time, either in the administrative, executive, or mechanical branches of the establishment. It is not improbable that Sir John's thoughts were *above* money-making. Capt. Harness, R.E., Deputy-Master under Sir John Herschel, was a gentleman of great ability unquestionably, and he re-arranged and re-modelled the officiai and operative staff with an eye—and a keen eye, too—to the public service; but he was too valuable a man to be allowed to remain in so unimportant and narrow a field of action, and he was transferred, first to the Commission of Works at Dublin; then to the War-office, Pall Mall; finally to Hindostan, to fight the Sepoys. Many of Captain Harness's plans for the working of the Mint remain in efficient force at present, and there can be no question that his perspicacity and energy would have induced other new rules to be established for the economical government

Digitized by Google

of the works and work-people, had he been suffered to remain at Tower-hill.

After the retirement of Captain Harness, the posts of Comptroller and Deputy-Master were amalgamated, and fortunately for the interests of the establishment and of the State, in April, 1855, Dr. Graham, F.R.S., became Master of the Mint. That gentleman has proved a 'master and worker' indeed. The political Masters of former times received £2,000 per annum, and did nothing; the permanent Master of to-day enjoys a salary of £1,500, and works hard. Such is one of the changes made in these latter days of the Mint.

Without further prelude we now proceed to the task of describing the mode of transforming auriferous sands into current coin of the realm. Of the manner in which the raw material is obtained, of quartz-crushing, and the operations of the digger in his pursuit of the yellow earth, our readers probably know enough already. On the arrival of a lucky digger, he usually disposes of his gains to a bullion dealer at the market value, or to the Bank of England, at such a rate as an assay of its quality made by the Bank refiners warrant the Old Lady in allowing for it. At Brown and Wingrove's, Wood-street, Cheapside, the Bank have their bullion intended for coinage reduced to standard, and cast into ingots. These latter are returned to Threadneedle-street, and thence transferred in bags placed in iron-bound and trebly-locked boxes, and by means of carriers' carts, to the Mint.

These carts—well known to the Mint police, as are the sturdy porters who sit on the lids of the gold-chests, and are their only guards through the City—are admitted at stated intervals, and disgorge their rich freight through one of the open windows of the Mint office. The ingots are then placed in the scales in presence of a Bank and several Mint officers, their weight duly registered, and receipt given for them. Assay pieces are next cut from them, and they are numbered so that reference may be made to each ingot after the Mint assayer has operated upon his assay pieces, and determined their "betterness" or "worseness" (these terms are still in use) than standard gold. The assayer's report determines the amount of alloy necessary to be added in the melting of the ingots for conversion into bars. A similar process is observed with silver as regards the assaying, though silver is purchased for coinage by the Mint Master himself in the cheapest market—as is copper for the inferior coinage—and does not, in other than exceptional cases, as that of worn coin, for example, come from the Bank at all. Into the process of assaying it is not our intention to go, that is purely a chemical matter, and is practised largely by other professionals than Her Majesty's coiners.

Assuming, then, that the assayers of the Mint have obtained assays of a batch of golden ingots, and duly noted, registered, numbered, and reported them, there is no reason why they, the ingots, should not be transferred to the first operative department of the Mint, the melting-house, and they are so forthwith, the melter in chief signing a receipt for them, and afterwards checking their weight by his own weighing beam.

(To be continued.)

Literature.

On Liberty. By JOHN STUART MILL. London: John W. Parker and Son, West Strand. 1858.

LIBERTY is man's dearest possession. The love of it is in proportion to his wealth and vitality and constitutional endowment. All things suggest it to him; the wide sky, the wide sea, the fair cloud that streams from horizon to horizon. The true man will part with one thing after another, but never with it. At any encroachment on it, his blood is up, and the whole man soon in a blaze.

The above-named little book, although scrupulously sensitive, even to minutest details, to one man's invading by a hair's breadth the orbit of another, is yet in the main a book about true liberty—the liberty of the intellect to see and say its utmost; of individual character to assume its own native shapes, and plan its own life, and go its own way in the world. The book is a growth rather than a manufacture; or if the most practised hand has manipulated it, the raw material was the genuine product of life and nature, and of the choicest sort. The freedom here spoken of was first lived and practised; the words are but the voice of experience and ways of life of long years. A most robust, sturdy, entire, and fearlessly outspoken freedom is here. How many noble English souls have hailed this book as a fresh breeze sprung up in a stagnant, sultry air. How many have read it, looking out as from behind prison-bars, secretly pining to be out there in the sunshine and free space in which this thinker disports himself.

The reader will be struck with the dedication: "To the memory of her who was the inspirer of all that is best in my writings," whose "all but unrivalled wisdom" the writer vainly strives to reach. This rigorous logician, then, who always will have his feet upon the firm earth, has an unfathomable heaven over him, wherein he gives place and shape and name to the imaginings of the soul's love and wonder. This sturdy warrior, so erect in his self-sovereignty, bows down before another and a gentler; like his brothers who lie in effigy in our old churches, who loved even the dog at their feet, much more the wife at their side, and who crossed their arms upon their breast in pious adoration beneath the temple-roof and the glory beyond.

The book goes to the root of all liberty, namely, this: that the one thing binding on a man, which comprehends all others, is the unfolding of the nature he is endowed with to the utmost fulness and completest harmony it is capable of reaching. This is no theory or opinion; it is an intuition of common sense. Man's chief beliefs are necessities of his nature. As he cannot be alive bodily, and use his organs without receiving certain general impressions of things corporeal, so he cannot exist mentally, and use his mental organs, without coming to certain conclusions about things incorporeal. Now, we have but to look on human nature with eyes, and not through spectacles, and we cannot mistake what it is for; namely, to be developed to its utmost of harmonious strength and fulness, like any other product of nature. Nothing native there is to be suppressed; nothing alien to be imported. We conjure you to give us the man, the whole man, and nothing but the man. Healthy artists complain of a purist model in painting, which abjures the bright-red arterial blood in the cheek and the fire in the eye; and healthy men have to complain now-a-days of a meek, pale, innocent, bloodless, nerveless type of character set up for their imitation. We want the whole man; we want self-assertion as well as self-denial; passionate impulsive energy as well as innocent submissiveness; laughter as well as seriousness; self-esteem, and high honour, and magnanimity, side by side with lowliness and meekness. Above all things we want whatever is unique, eccentric, and original, in the man. As every man can, with brain, or tongue, or head, do something better than his neighbour, we want him above all things to do that something, whatever else he leaves alone. But more than all, pleads this little book, we want to the full the originality of original men. They alone discover new thoughts, new modes of life, new paths for human activity. They alone keep society from sinking into pure mechanism and routine. They cannot take anything for granted, receive anything at second-hand, but must go to the ground, the reason, the meaning, the living soul of it. And so they make all things new for us, generation after generation. They are the salt of the earth; without them human life would become a stagnant pool.

On the whole, the book is a sorrowful one, full of warning and protest. "A man cannot get a coat or a pair of boots to fit him, unless they are either made to his measure, or he has a whole warehouseful to choose from; and is it easier to fit him with a life than with a coat, or are human beings more like one another in their whole physical and spiritual conformation than in the shape of their feet?" "The general tendency of things throughout the world is to render mediocrity the ascendant power among mankind. Individuals are lost in the crowd. Energetic characters are becoming merely traditional. Collective mediocrity is all the greatness England can boast of now. But it was men of another stamp than this that made England what it has been, and men of another stamp will be needed to prevent its decline." "In our times, from the highest class of society down to the lowest, every one lives as under the eye of a hostile and dreaded censorship. All ask themselves, What is suitable to my position? What is customary? It does not occur to them to have any inclination except for what is customary. Thus the mind itself is bowed to the yoke." "Public opinion in England is as efficacious as Laud in keeping down heretical thoughts; a convenient plan for having peace in the intellectual world, and keeping all things going on therein very much as they do already. But the price paid for this sort of intellectual pacification is the sacrifice of the entire moral courage of the human mind." Such are the plaintive reminders of this book; it is for us to profit by them.

Popular Tables. By CHARLES M. WILLICH, Actuary and Secretary to the University Life Assurance Society. *Fourth Edition.* London: Longman and Co. 1859.

MR. WILLICH'S Tables, in their former editions, have taken so high a place in the estimation of men of business that they no longer need the commendations of the press. The present edition contains, however, so much new and valuable matter that it would be most unfair to the author did we omit to particularize some at least of his new additions. The first of these which claim attention are three new tables showing the prices which may be paid for property depending on the DURATION OF LIFE, so that the purchaser may receive a *certain* high rate of interest on the capital invested, while the re-investments to replace capital are calculated, on an average, to be made at three per cent. A formula is also given for calculating questions which are not resolvable by the tables. The next new table is one for calculating the expectation of life, and is based upon a formula given in an earlier number of the MECHANICS' MAGAZINE as an abstract of a paper read before one of the learned societies. The next is an exceedingly interesting table of Bank Discounts, showing in one view the progress of the Money Market during the last 14 years, and how it was affected by panics, the Russian War, and the Indian Mutiny. The *Mathematical* Tables now comprise the squares, cubes, square roots, cube roots, reciprocals, logarithms, common and hypobolic trigonometry, circumference and area of circles (in a note, page 180, is given a paper laid before the Royal Society, on a simple geometrical quadration of the circle), length of circular arcs, chords, diagonal of squares, solidity and superficies of spheres. Many of these are, of course, of the first importance to scientific men, both theoretical and practical.

The Astronomical Tables, including 56 of the asteroids, are brought up to the latest period, and they have been submitted to the revision of J. C. Adams, Esq., the discoverer of Neptune.

Table VIII, page 88, gives the average price of consols from 1731 to 1858, together with much information connected with the past; under what administration the Government was carried on; progress of National Debt; if peace or war, &c., &c.

At page 80, a table on *Decimal* Coinage is given. If the decimal system should ever be carried out according to the recommendations made, the small table for converting the old into the new currency will be useful.

It is not possible here to give any idea of the extent and comprehensiveness of the tables in this volume. It is a book to be at the hand of every educated man who has the least occasion to refer

Digitized by Google

to such standard facts as a clever man can put into tabular form for him. Even those who possess former editions of the work will not attempt to dispense with this if they are wise.

Mental Arithmetic. By HUGO REID, Author of the "Principles of Education," &c. London: Longman, Brown, and Co. 1859.

THIS little book (published for a shilling) deserves to sell by tens of thousands, for its statement of the principles of arithmetic is as clear as a learner can require, and its exercises are such as will be of great service to the teacher. Indeed, the author's explanations of the arithmetical principles appear to us to be the most lucid and correct that we remember having seen.

THE NAVIES OF ENGLAND AND FRANCE.

(From *Blackwood's Magazine* for June, 1859.)

ALL critics, all reports, all writers, in their estimate of the comparative strength of the countries in steam force, select 1852 as the commencement of the steam era, and draw their conclusions from the progress made by each from that time. The relative standing of the navies was then according to the old ratio. England had 5 steam liners afloat, and 12 building, besides 4 block-ships. 24 frigates, 56 corvettes and sloops, and 66 gun vessels, brigs, &c. Of sailing ships she mustered 66 afloat and 7 building, 88 frigates, 84 corvettes and sloops, small vessels 45, making a total of steam 176, of sailing 299. France had 2 steam-ships of the line afloat, 4 building, 21 frigates, 28 corvettes, 3 on the stocks, 64 small craft, 2 in preparation. Of sailing ships there were 25 available, 20 in construction, 36 frigates, and 150 corvettes and smaller craft, with 27 to be added, constituting a fleet, ready and designed, of 176 steam-ships and 258 sailing vessels. In these numbers are seen the old ascendancy, both in the present strength and the future promise, in the possession of the new element and of the old convertible material. We come to the year 1858, and find the statistics numerically unaltered. Still in numbers and in figures Britannia seems to rule the waves. She has raised her steam navy to 464 ships, her sailing force counts 296 more. Against this, France shows 264 steam, 144 sailing vessels. Still an analysis of the respective effectiveness of the navies as national forces admits a result rather different from the numbers. In the line of-battle power, that which would most essentially affect a contest for supremacy, the fleets are equal—each could arrange 29 ships. In frigates France has a preponderance of 8, but in the corvettes and gunboats—the light infantry, the skirmishers, the covering force of future battles and attacks, a force too little thought of, too much underrated in the calculations — England has still a vast superiority. We shall now, however, drop comparisons for a while, and adhere to a statement and dissection of the navy of France, reserving conclusions until we have fairly stated the results and the probabilities of the efforts made by these two great nations for maritime supremacy. The present product exhibited by France is a formidable proof of her power, a worthy test of her resolve, a strong development of her policy. We must again descend to figures; they are dull dry things, but in this case the only real elucidation of facts. The French navy consists now of 29 steam liners, and 2 about to receive engines (which may be now included) according to the English official report. From other sources there would appear to be one more. Of these, 10 are entirely constructed for the new power; of the remainder, 7 were old ships converted; the others were originally laid down or commenced for sailing vessels, and then altered on the stocks in different stages of completion. Out of this number there are five first-class ships, one of which is new, and another has only auxiliary horse-power, and there are six only carrying 100 guns or upwards. Thus the line-of-battle force is represented by 32 ships, mounting 2,878 guns, and possessing 20,700-horse power. The "Conversations Lexicon" asserts as a fact that these ships are all of a very superior class, and that in their quality they offer a counterbalance to a superiority of numbers. This writer appears from the beginning to have indulged in a remarkable fallacy relative to the naval architecture of the two countries. He commences on the theory that the French ships in the old war were very inferior in construction, in durability and strength, and goes on to show that now the comparison is entirely reversed. We believe—from the best and most impartial evidences, from facts and the opinions of practical men who have investigated the subject closely, not viewed it *à la distance*—that the very contrary of this judgment would be the truth. A French writer says on this subject: "En effet, les vaisseaux lancés de 1760 à 1791 furent peut-être les plus beaux, les *plus solides*, et les meilleurs que nous ayons jamais eut;" and states further, that these same ships illustrated the perfection of naval art, and excited the envy of all the great maritime powers, not even excepting England. Mr. Reed, one of the leaders of the modern school of architecture, strongly confirms this statement. "The science of naval architecture," he says,* "was so greatly advanced on the Continent, and so much neglected in England, during the last century, that the forms, dimensions, and speed of the ships of the British navy, were for the most part inferior, class for class, to those of the ships of every other nation with which we had to cope." "Happily for us, and for those colonies and states whose liberties depend on our naval supremacy, the tactics of our admirals and the bravery of our men won for us much more than we lost by the inferiority of our vessels." Yet, spite of all the concurrent testimony of experience and opinion, the German essayist would fain make us believe that our success was owing to our superior capacity for being rammed, and that the solidity of our planks and timbers, rather than the mobility of our ships, won us our victories. This fallacy is well capped by the assertion that the French have at present gone beyond us in the excellence of construction, and have produced the most superior types of vessels of war. Strangely enough, our own authorities would seem rather to encourage this idea; whether from a desire to be humble, or to give impulse to competition, it were hard to say. A wag used to say of a friend, noted for constitutional discontent, that whereas other men always made their geese swans, he delighted to prove his swans to be geese. This is undoubtedly with us a national propensity. In this case, however, we certainly have the swans, whatever we may say of them. The authority we have above quoted, in continuation of his subject, says: "Happily, also, this inferiority no longer exists. The ships of our navy have not only ceased to be imitations, but have become the models for the navies of the world." All who have had the means of comparison, either under a war or peace aspect, must fully agree with him. Even unprofessional eyes which saw the Renown and Prince Albert floating side by side in the Rade of Cherbourg with the Napoleon and the Bretagne, recognised their superiority in beauty and symmetry, and acknowledged the strong contrast they offered to the heaviness of the Austerlitz and the ugliness of the Donawerth. "Ugliness," Mr. Reed is right in saying, "is pardonable in a war ship, if anywhere; yet even here beauty is becoming." More than this, symmetry is strength, and proportion is power as well as beauty. In these respects the English vessels fairly challenged comparison. The practised ken, too, which looked not on ships as masses of woodwork and guns, but as motive things which were to be propelled and handled tactically, which were to buffet with waves, saw, in their lightness and buoyancy, in their capacity for carrying their guns high out of the water, in the fighting space betwixt the guns, qualities which would tell with advantage in exercise or in the real work of war. Even the Napoleon, the famous type, offered no temptation for copy to those who possessed a Renown. Those who saw the tests of the Baltic and Crimean operations, must have acknowledged also the handiness and manageableness and seaworthy capabilities of our modern ships, and felt that at last, after many trials and haltings betwixt systems, we had attained an excellence in the building art worthy of our naval character and our maritime pretensions. Much has been said of the ten 80-gun ships which were converted, and are supposed to be inferior to anything of their class in the rival fleet. It is true that they are very unequal to the new creations, and should not, or will not, of course, be perpetuated. But as makeshifts they are not contemptible; many of them indeed, in nautical parlance, are good wholesome ships, and would hold a good place and do good work in a line of battle. The Royal George might fairly be matched with the Montebello or Charlemagne, and the rest would be certainly equal to the ships in the French navy which had undergone the like kind of transformation. On the components of the new force we may well look with satisfaction, both as to the present development or the future perfection of the science of ship building. The Orion, Renown, Conqueror, James Watt, Princess Royal, Duke of Wellington, *et hoc genus omne*, whether as models or sea-boats, as specimens of art or engines of war, are, we believe, the best types which naval architecture has yet exhibited to the world, and "in dimensions, forms, means of propulsion, and powers of attack and defence,"* may justly be said to be "the embodiments of all such sound and well-tested improvements as have hitherto been found compatible with the purposes for which ships of war are designed." Thus the French line of-battle ships stand before us as a formidable and respectable array of goodly models and engines of war; but there is nought in them to warrant the idea that they assert for their country a supremacy in the art power of construction.

We pass on from the line-of battle power to the frigate force, and here we perceive that the greatest effort has been made, and the greatest results obtained—37 frigates afloat, against 28 English, give a preponderance in this arm of 9, and those in preparation will further increase it. The armament and horse-power they represent is also great, being 1,216 guns, and 17,000-horse power. The total force of frigates and line of-battle ships afloat at the close of 1858 was 69, and of these 16 of the first and 30 of the latter had been constructed in the seven years, giving an average of between 6 and 7 in the year. In the smaller vessels the increase had not been so great; still, however, the French navy was stronger in 1858 than it had been in 1852, by 100 ships of different classes. This was good earnest work, yet after all not so extraordinary for a great power, professing great resources, engaged in the reconstruction of her navy. It must be remembered that in these calculations we allude only to the ships actually complete, and which might presently be placed on the seas against an enemy. It was good work, yet not enough for the supremacy. The energy and resource of her rival, though taking a different direction, had produced greater results in numbers, and had created an immense aggregate of war power. The comparative results will be seen below:—

—	Line-of-batt.-ships†	Frigates, screw.	Ditto, paddle.	Corvettes, screw.	Ditto, paddle.	Mortar ships.	Floating batteries.	Gun and despatch vessels, screw.	Ditto, paddle.	Gunboats, screw.	Troop and store ships, steam.	Tenders, tugs, &c.	Block ships.	TOTAL.
France	32	1	19	9	9	..	5	17	50	28	22	..	..	222
England	33	1	9	38	35	4	8	29	25	161	15	47	9	429

In respect of numbers this navy would demand no comment—it is not above that which a first-rate power might deem necessary for the

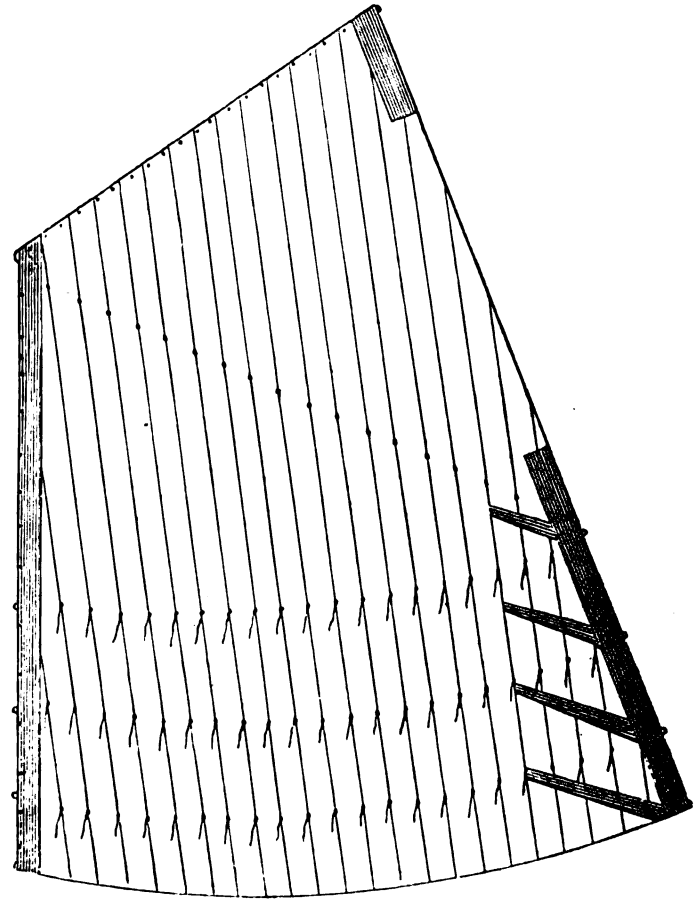
support of its dignity, though far beyond that which France has for many years been able to maintain, and still further beyond in power, as this is an effective statement, and includes no dummies or lame ducks. It challenges attention, however, as to the rapidity and efficiency of its construction, and the proportion of its parts. The same purpose is apparent in both—the same intent coincident. The policy which resolved the one designed the other. That policy is to concentrate all the national strength and force on that element of the naval force which shall best effect the maritime and the military supremacy. Thus we see that the ships of battle and the heavy frigates—all carrying heavy guns, and propelled by great horse-power—constitute the main classes of the fleet. The steam transports, too, occupy a prominent place, and a still greater one in the designs for the future. The building of smaller ships, cruisers, gunboats, &c., has been altogether abandoned of late, and omitted in the calculations; whilst the other classes have been increased by extraordinary efforts. All this would seem to denote that the great aim has been to make the navy effective for contest on the seas, and to combine the maritime with the military force of France, and make it an agent, and a powerful one, in the plans and strategies of future conquest and aggression. The director of the present movement in the naval development of his country, has not apparently shown his usual prescience and forecast in the recognition and adoption of a coming power. The mind which had foreseen and forethought the probable means by which steam would act, has overlooked the most fitting agents for the introduction of the projectile power, which now looms before us as the chief and most terrible agent in the operations of war. He has provided for defence against it, in the construction of iron-cased vessels; but the gunboats and small craft, which, from their mobility and their small size, will be probably the machines by which rifled cannon will be first and most efficiently applied in the purposes of attack, have been omitted altogether in his estimate of the present and future requirements of the French marine. This light force will be henceforth, doubtless, what riflemen are to an army, and by their capability of maintaining a long range and well-aimed fire—which would not be possible in the *mêlée* of a general action—will be powerful auxiliaries or opponents of a line of battle.

(To be concluded in our next.)

VEGETABLE LEATHERS.

HAVING seen some specimens of these leathers, as well as various articles of utility manufactured therewith, we have been induced to pay the extensive works of Messrs. Spill and Co., the eminent Government contractors on Stepney Green, a visit, in order to cull sufficient to place upon record the present position of artificial as a substitute for real leather. The face and general character of the vegetable leather resembles the natural product so closely that it is only by actual examination that the difference can be determined. This is more particularly the case in that description which is made for book-binding, the covering of library tables, and like purposes. Amongst other advantages it possesses over leather proper, may be mentioned, that however thin the imitation is, it will not tear without considerable force is exercised, that it resists all damp, and that moisture may be left upon it for any period without injury, consequently, it does not sodden or cockle, is always dry, and its polish is rather increased than diminished by friction. Add to these facts that any attempt to scratch or raise its surface with the nail, or by contact with any ordinary substance, will not abrade it, and enough will have been said to justify its entering the lists against an article of daily use, which has of late years been deemed far from sufficient for the demand, and has consequently risen in price to the manifest loss and injury of every class of the community. We believe that the largest entire piece of real leather that can be cut from a bullock's hide, is not more than seven feet by five, and this includes the stomach and other inferior parts. Vegetable leather, on the contrary, is now produced 50 yards in length and 1½ yards wide, every portion being of equal and of any required thickness, and the smallest portion is convertible. We were agreeably disappointed, however, to find that instead of vegetable leather being a discovery requiring the aid of ourselves and contemporaries, it was, although so young, an active agent in the fabrication of numerous articles of daily requirement, and that it had already become the subject of large—indeed, we may say enormous—contracts. Caoutchouc and naptha are used in its manufacture, but by a process known to the senior of the firm, who is himself an accomplished chemist, all odour is removed from the naptha, and the smell of vegetable leather is rendered thereby less in strength, if anything, than that of leather. The principal objects to which it is at present applied, although it is obvious it will take a wider range of usefulness than leather itself, are carriage and horse aprons, antigropole, soldier's belts, buckets which pack flat, harness of every description, book-binding, &c. For the latter its toughness, washable quality, and resistance to stains render it remarkably fitted. Its thickness, which may be carried to any extent, is obtained by additional backings of linen, &c., cemented with the caoutchouc, and its strength is something marvellous, while in the all-important commercial view, it is but one-third the price of leather. Many of the articles we were shown possessed the appearance of much elegance and finish; but it was curious to observe that although most of these could be made without a stitch, and within the factory itself, a deference to the feelings of the workmen in the several trades has been shown by the firm, and the material is given out as ordinary leather to undergo the process of the needle, which it submits to with a greater facility than its original prototype. Perhaps this concession upon the part of the discoverers is both wise and politic, inasmuch as their object is more to manufacture and supply the article in the gross to the saddler, &c., than to make it up upon their own premises—a monopoly which might become exceedingly formidable and injurious. We think we have glanced, although hastily, at the principal features of this important discovery, and said quite sufficient to raise the curiosity of all interested in the advance and consequent cheapening of our manufactures.

GUTHRIE'S IMPROVED MAINSAIL.



MR. T. GUTHRIE, of Newcastle, who has had much practical experience, both on board ship and as a sail-maker, submits that ordinary mainsails have defects which it is easy to get rid of. Starting with the correct principle that it is desirable to keep such sails as flat as possible while under the pressure of the wind, he proposes to form them with the widths of canvas cut and arranged as illustrated in the annexed engraving. It will be observed that the chord of the arc which the foot of the sail forms, is in a line with the weft-threads of the canvas, so that when the strain of the "sheet" is brought upon the foot of the sail, the weft-threads are put into a state of tension, and resist all stretching, allowing the sheet to be made fast at once to its proper place on the boom. In ordinary sails this is not so; the tension put upon the foot of the sail by the sheet brings a diagonal pull upon the width of canvas, in consequence of which they are invariably liable to stretch, as will be well understood. Another advantage which Mr. Guthrie claims for his improved sail is, that the after "leech" is cut upon the cross, and, therefore, gives to the wind; consequently, there is no need of taking "slack" in the seams, which, he says, is a great detriment to the wear of the sail. He considers that his improved sail will last one-fourth longer than the ordinary mainsail. At the same time it costs no more.

Proceedings of Societies.

THE GEOLOGICAL SOCIETY OF LONDON.

May 18.—Major-Gen. Portlock, Vice-President, in the chair. Richard Meeson, Esq., Grays, Essex; Graham Stuart, Esq., Brindcliffe, Sheffield; and Col. Stepney Cowell Stepney, St. George's Place, Hyde Park, were elected Fellows.

The following communications were read:—

1. "Palichthyologic Notes, No. 12. Remarks on the Nomenclature of the Fishes of the Old Red Sandstone." By Sir P. Egerton, Bart., M.P., F.R.S., F.G.S. &c.

2. "On the Yellow Sandstone of Dura Den and its Fossil Fishes." By the Rev. John Anderson, D.D., F.G.S., &c.

June 1, 1859.—Major-Gen. Portlock, Vice-President, in the Chair. J. Lamont, Esq., Knockdow, Argylshire, and W. Longman, Esq., 36 Hyde Park-square, were elected Fellows. The following communications were read:—1. "On the Sinking for Coal at the Shircoaks Colliery, near Worksop, Notts." By J. Lancaster, Esq., and C. C. Wright, Esq., F.G.S. In two shafts sunk for the Duke of Newcastle on the north-west side of his estate of Worksop Manor, it was found that the New Red Sandstone and marl have a thickness of 54 ft., and the Permian beds 112 ft.; the latter consisting of hard yellow limestone (54 ft.), blue limestone and shale (20 ft.), blue shale (33 ft.), and soft gritstone, probably equivalent to the "Quicksand" of the north (5 ft.). Below the gritstone the coal-measures commence with 5 feet of blue shale, in which there are four bands of ironstone; another band, 15 inches thick, lies immediately below. This iron-ore is chiefly in the state of peroxide, gives an average of 42 per cent. of metallic iron, and promises to be of great economical value. The first seam of coal (2 feet thick and of inferior quality) was cut at a depth of 88 yards. Four yards below this is a compact sandstone 66 feet thick. The sinking through this rock occupied 20 months; each pit made 500 gallons of water a minute, which was stopped in detail by cast-iron tubing. The pressure from the gas at the bottom of this thick rock was at times as high as 210 pounds per square inch, but is now about 196 pounds per square inch. Shales, with coal-seams and bands of ironstone, all thin or of inferior quality, were met with in the next 170 yards. At 346 yards the first thick coal was cut, and found to be 4 ft. 6 in. thick, and of good quality. This is considered to be the "Wathwood Coal." The "Top Hard Coal" was cut at a depth of 510 yards, and found to be 3 ft. 10 in. thick; the strata intervening between this and the "Wathwood Coal" were found to have much the same characters and thickness as they are known to have elsewhere. The sinkings were commenced in March, 1854, and perseveringly continued until their completion on February 1st, 1859. Altogether 37 feet of coal were passed through; but only four seams are of workable thickness. The authors of this communication remark that the district appears to be remarkably free from faults, that the dip decreases considerably towards the east, and that the "Top Hard Coal" appears to thin out eastwardly. [This paper was illustrated by carefully-prepared sections (vertical and horizontal), and by specimens of the ironstones, &c.] 2. "Notes on the Geology of Southern Australia." By A. R. C. Selwyn, Esq., Director of the Geological Survey of Victoria. In a letter to Sir R. I. Murchison, F.G.S. Mr. Selwyn remarked that as to the impoverishment of auriferous veins in depth, the only evidence of such being the case in Victoria is the great richness of the older drifts, for, judging from the large size of the nuggets sometimes found in the gravels, compared with that of the nuggets met with in the gold-bearing quartz-veins (usually from about ¼ dwt. to ¼ oz., though occasionally as much as 12 ozs. or even 13 pounds), the upper portions of the veins, now ground down into gravel, were probably richer in gold (as formerly suggested) than the lower parts, now remaining. As far as actual mining experience shows, some of the "quartz-reefs" in Victoria prove as rich in gold at a depth of 200, 230, and 400 feet as at the surface; the yield, however, fluctuates at any depth yet reached. According to the author's latest observations, the gold-drifts, and their accompanying basaltic lavas, are of Pliocene and Post-pliocene age. Miocene beds occur at Corio Bay, Cape Otway coast, Murray basin, and Brighton; and Eocene beds on the east shore of Port Phillip, Muddy Creek, and Hamilton. Two silicified fossils (Echinoderm and Coral), thought by Prof. M'Coy to be of Cretaceous origin, have been found in the gravel near Melbourne. This letter also contains some remarks on the probability of some of the coal of Eastern Victoria being of "Carboniferous" age—on the occurrence of Silurian fossils in the rock of all the gold districts—on the newly-discovered bone cave at Gisborne, about twenty-five miles north of Melbourne—and on the progress of the Geological Survey of the Colony. [Portions of the Geological Survey Map of Victoria, lent by the Secretary of State for the Colonies, and specimens of gold, &c., lent by Prof. Tennant, F.G.S., were exhibited in illustration of this paper.] [Fossils from Mayence, &c., presented by W. J. Hamilton, Esq., For. Sec. G.S., Fossil Trigoniæ from South Africa, presented by Capt. Harvey, R.E., and a series of Photolithographs of fossil foot-tracks from Connecticut, lent by Dr. Bowditch, were exhibited at this meeting.]

ROYAL AGRICULTURAL OF ENGLAND.

May 27.—A Special Council was held, by order of the President, Lord Washingham in the chair. The report of the Finance Committee was read. A communication having been made by the Council to Mr. Hudson, the Secretary, and his reply having been received, it was unanimously resolved on the motion of Mr. Milward, seconded by Lord Feversham, "That Mr. Hudson be suspended from the office of Secretary from this time." On the motion of the Hon. Col. Hood, seconded by Mr. Jonas, "That Mr. Braindreth Gibbs be requested to accept the office of Honorary Acting Secretary *pro tem.*" On the motion of the Hon. Col. Hood, seconded by Lord Feversham, "That all letters be addressed to Mr. Brandreth Gibbs, as Honorary Secretary to the Society." On the motion of the Hon. Col. Hood, seconded by Mr. Jonas, "That these resolutions be made known to the public journals in the usual manner." The Council came to other resolutions relative to the details rendered necessary for carrying into effect the above decisions, and gave orders accordingly.

June 1.—At a Monthly Council (for the transaction of business), held on this day, the Right Hon. Lord Portman, Trustee, in the chair, several new members were elected. The Chairman of the Finance Committee, presented the monthly report on the accounts. Mr. Wren Hoskyns, Chairman of the Chemical Committee, reported that Professor Voelcker had analysed a specimen of Mangel that had been stored two years, and that the Professor will be prepared at an early meeting of the Council to make some remarks upon the analysis he has made. Lord Leigh, Vice-Chairman of the General Warwick Committee, reported the recommendations of the Committee. The President was requested to summon a Special Council for 10 o'clock on June 22, for receiving the report of the Special Committee on accounts, and of the Judges Committee, and appointing the judges for the several departments of live stock, implements, and also for cheese and wool at the Warwick meeting. On the motion of Colonel Challoner, the Right Hon. Lord Leigh was unanimously appointed Steward elect of implements. The Council gave authority to the House Committee as to carrying out the details of matters intrusted to them.

ASSOCIATION OF FOREMEN ENGINEERS.

June 4.—The usual monthly meeting of the above-named society took place at the Bay Tree Rooms, City. An adjourned discussion of Mr. Briggs' paper on the "Concussion of Water," was the principal feature of the evening, the election of two auditors, Messrs. Hosken and Stabler, however, preceding it; and it was opened with a supplementary paper by Mr. Briggs himself on hydraulic matters generally. The very great importance of a knowledge of all the phenomena relating to pumps, pumping, and hydrostatic arrangements was urged by that gentleman, who proved yet further his own mastery of the subject. Mr. Warner coincided almost entirely with the statements of the author of the paper, and spoke of the laws which governed the passage of fluids through pipes connected with pumps. The hydraulic ram afforded Mr. Warner useful matter for illustrating his views, and Mr. Stabler, who followed, and who has had considerable experience in the matter of fire engines, gave practical information on these valuable adjuncts of civilisation. Other speakers remarked upon the use of scientific discussions to persons situated as the Members of the Association were, and of the indirect advantage which their employers must derive from them. These last remarks, the Chairman, Mr. Joseph Newton, warmly agreed with; and he wished that employers were present on all occasions of their meetings. A vote of thanks to Mr. Briggs and the announcement of a paper on the first Saturday in July, by Mr. Stabler, on the "Economical Formation of Steam," brought the meeting to a satisfactory close.

MEETINGS FOR THE ENSUING WEEK.

MON.—*Royal Geographical Society*, the Earl of Ripon, President, in the chair. 1. Capt. R. F. Burton, F.R.G.S.; II. Capt. J. H. Speke, F.R.G.S. "Explorations in Eastern Africa," 8½ p.m.

TUES.—*Royal Inst.*, General Facts and Leading Principles of Geological Science," by John Morris, F.G.S., at 3 p.m.

WED.—*Geological*, Special General Meeting at 8 p.m., afterwards the following papers will be read:—I. "Notes on Spitzbergen," by A. Lamont, Esq., communicated by Sir C. Lyell, F.G.S.; II. "On the Origin of Dolomites and Gypsums," by J. Sterry Hunt, communicated by Prof. Ramsay, F.G.S.: III. "On Tertiary Shells from Central India," by the Rev. S. Hislop, communicated by the President.

THUR.—*Linnean Society*, Professor Andersen, "On East Indian Salaces;" Rev. W. Foulkes, "On the Cultivation of the Cocoa Nut in Ceylon," at 8 p.m.

Chemical Society, "On Gas Analysis," Professor Williamson, at 8 p.m.

FRID.—*Royal Inst.*, Professor Faraday, D.C.L., F.R.S., M.R.D.; "On Becquerel's Phenomena of Phosphorescence," at 8 p.m.

SAT.—*Royal Inst.*, On Modern Italian Literature," by J. P. Lacaita, Esq., at 3 p.m.

LATHE FOR RE-TURNING RAILWAY WHEELS.

IN the annexed engraving we have represented in Fig. 1 a plan and in Fig. 2 a side elevation of a large double-face wheel lathe, adapted more particularly to the turning or trimming up of worn railway wheels, without the expense of taking them off their axles.* This machine consists of two strong and heavy headstocks bolted down to an irregularly-formed bed-plate slotted with grooves throughout its entire length, and recessed back both ways to take the T-headed bolts for holding down the two massive slide-rests shown in Figs. 3 and 4. The centres of these latter are 2 feet 10 inches from the bed, so that they will take in a wheel 5 feet 8 inches diameter. One of the headstocks—that through which the power is in the first instance transmitted—is permanently fixed to the bed, and the other can at will be shifted into closer proximity when required. The greatest length which can be obtained between the centres is about 10 feet, so that we have here a lathe competent to take in anything ordinarily required for either broad or narrow gauge. The main spindles, which are 9 inches diameter at the neck, are driven by 12 inch pinions gearing into teeth at the back of the face-plates, and keyed upon a long shaft *A*, which runs the greatest part of the length of the bed; this shaft is 4 inches diameter, and is supported upon 4 fixed and 1 sliding bearing, which last is bolted to the front end of the moveable headstock. The gearing is first actuated by the 4-speeded pulley *B*, having on its spindle a pinion of 9 inches diameter, which gears into a spur wheel 4 feet diameter, keyed upon the shaft *A*. This arrangement gives a proportion between the velocity of the first motion to that of the spindle of 28¼ to 1. The 12-inch pinion *C C*, which gear into the teeth of the moveable headstock, is fitted with a feather which allows it to slide along a groove on *A*, so that it can be driven when in any position along the bed. By this arrangement each railway wheel is driven from the face-plates without any dependence having to be placed upon the axles except for support, so that a heavy cut can be taken on both wheels at one time without any fear of a spring taking place. It will be seen also that one of the main spindles is fitted with a 3 feet pulley *D*, so as to allow of its being driven at a greater velocity for purposes of polishing or trimming up the journals of the axles when required. The moveable headstock is also supplied with an adjustable cylinder, in which the centre is fixed, and which can be screwed backwards or forwards by means of the wheel *E*, situated at the reverse end to the pulley *D*.

The great object in all large lathes is to make them so solid as, in effect, to nullify all vibration; and this is as important in the case of the slide rest as in the bed itself. The two slide rests, a slide and front elevation of one of which are

* Our correspondent who sends this article omits to state at whose works this lathe is in use. This shall be mentioned in a future number.

LATHE FOR RE-TURNING RAILWAY WHEELS

FIG. 1.

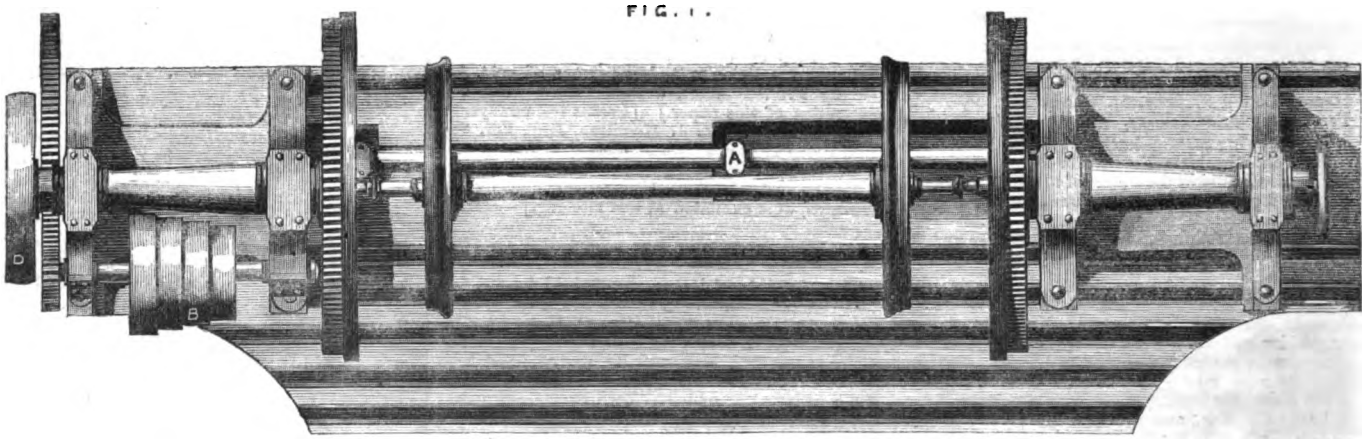

FIG. 2.

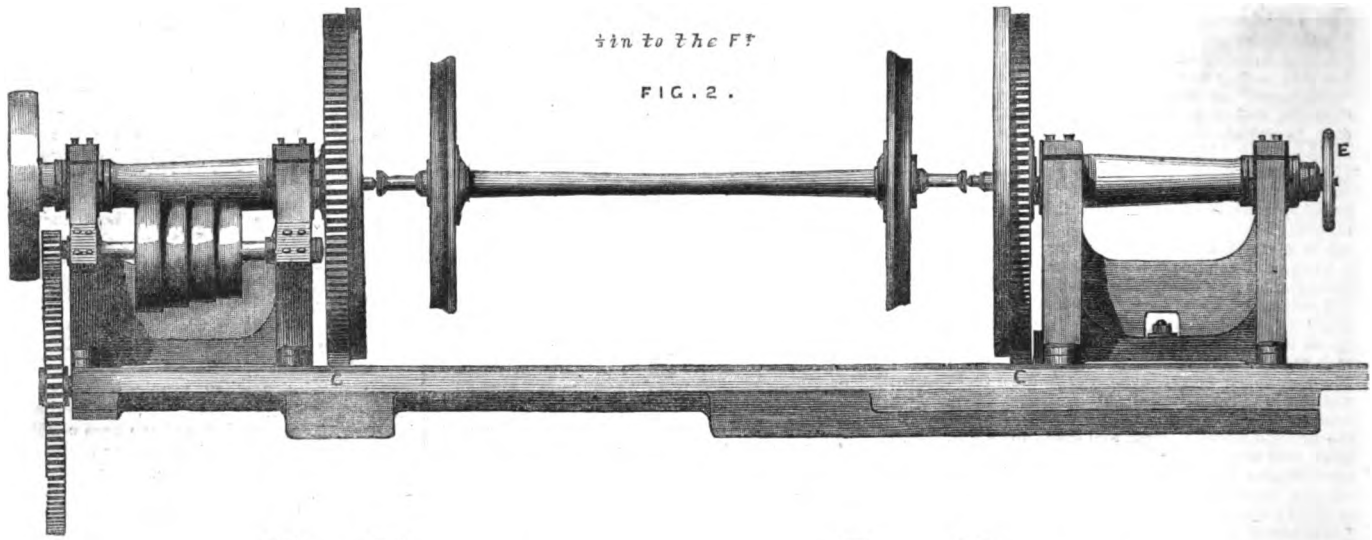

FIG. 4.

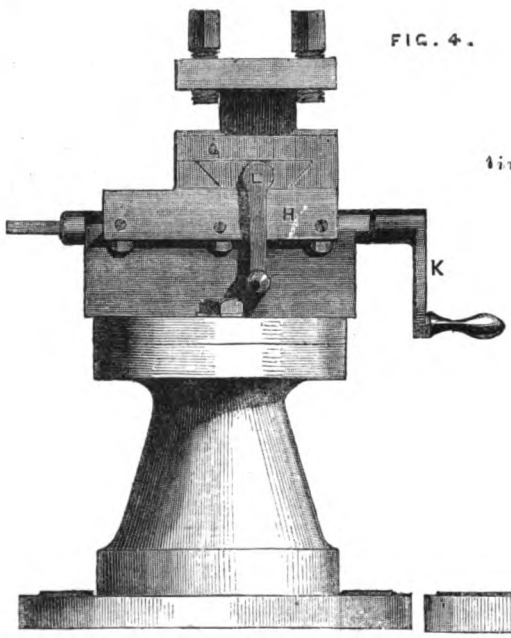

FIG. 3.

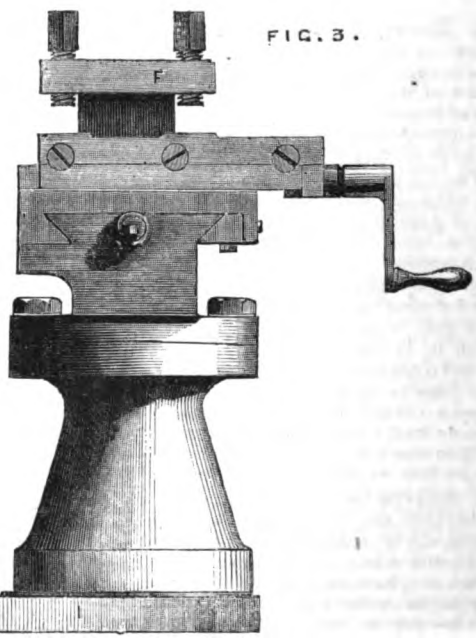

shown in Figs. 3 and 4, consist of strong coned columns rising from the tails or lower plates, which are planed true to rest upon the bed-plate fillets. The upper or sliding parts are made very strong with adjustable pieces, and the tools are clipped by means of steel pins working through square plates, which are one with the rests. This enables the tools to be placed in four different positions, according to the work required. The thickness of the metal of the columns of the rests is 1 inch; that of the tool plate *F* is 2¼ inches; the traverses of the two slides *G* and *H* are respectively 12 and 16 inches. The tail plate *I* is 2 feet 10 inches long, 2 feet wide, and 2½ thick; and the diameter of the bolts used to hold them down to the bed are 1⅛ inch. The lower screw for giving the feed, which is shown at *K*, is fitted with two square ends for the receipt of handles, which is useful in certain cases where the front one is inaccessible. Whenever this lathe is not required for re-turning purposes it can be used as a double-face plate lathe, and each face-plate and rest used separately, so that it forms a very useful and effective machine.

HEWITT'S PATENT SCREW PROPELLER.

FIG. 1.

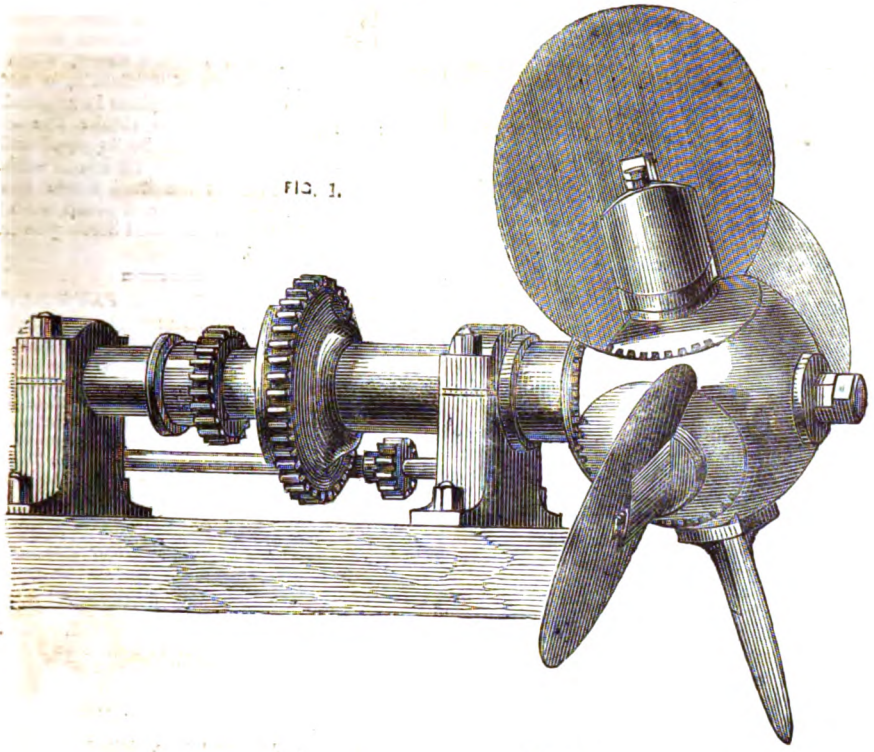

FIG. 2.

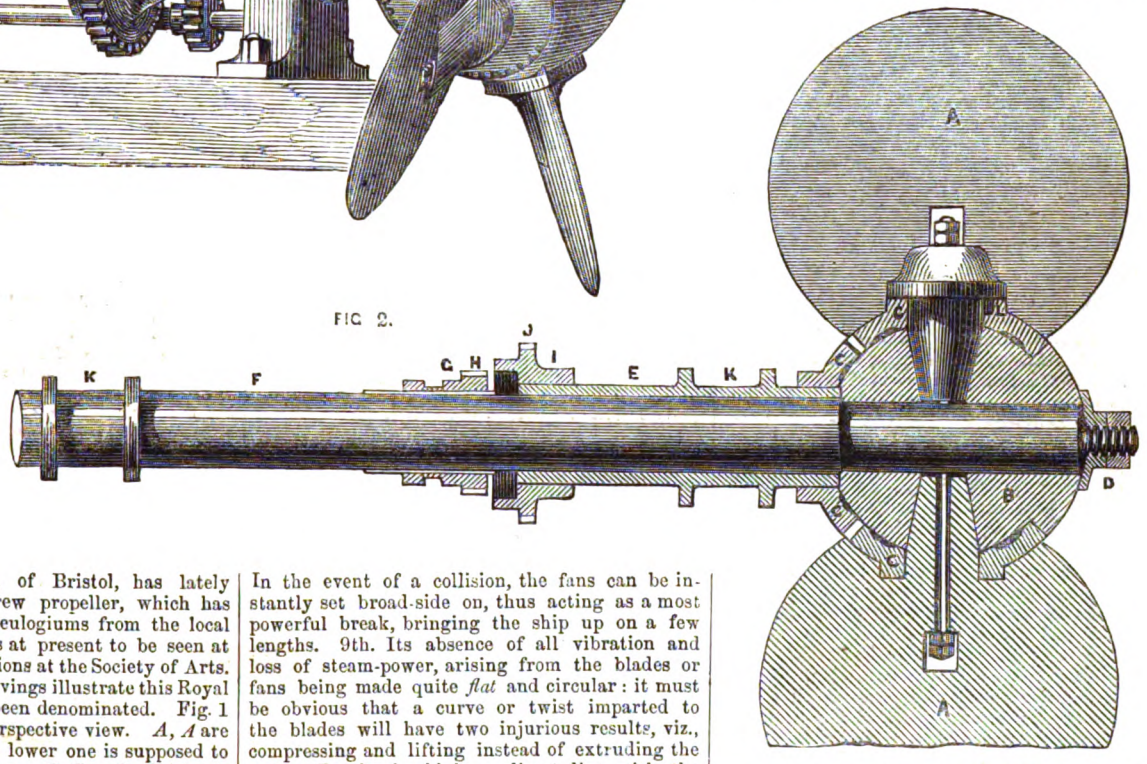

MR. WILLIAM HEWITT, of Bristol, has lately patented a form of screw propeller, which has called forth very warm eulogiums from the local press. A model of it is at present to be seen at the Exhibition of Inventions at the Society of Arts. The accompanying engravings illustrate this Royal Alfred Screw, as it has been denominated. Fig. 1 is a section; Fig. 2, a perspective view. *A, A* are the blades, of which the lower one is supposed to be in section; *B* is the boss; *C, C* are bevil wheels keyed on to the boss, and cogged round parts of their circumferences; *C* is a complete bevil wheel keyed on to the quill or tubular shaft *E*; *D, D* are nuts for securing the boss to the main shaft; *E* is the quill or tubular shaft for communicating motion to the fans or blades; *F* is the main shaft; *G* and *H* are a male clutch—an external wheel; *I* is the female clutch—an internal wheel; *J* is a spur wheel cut round the female clutch, into which a pinion works for adjusting or feathering the fans. The following are some of the important advantages which this invention is said to possess:—1st. Each of the parts can be made of *wrought* iron. 2nd. The pitch can be increased or diminished "to meet every contingency" with the greatest facility and ease. 3rd. It can be instantly feathered or placed on a neutral position previous to placing the vessel under canvas. 4th. A "disabled" fan can be immediately removed and re-placed by another without docking the vessel. 5th. The trunk or chamber provided for lifting the screw out of the water is entirely dispensed with. 6th. The arrangement for altering the pitch is within the ship, and, by the aid of a self-registering tell-tale, the angle or position is always indicated. 7th. Its non-liability to pick up a rope or chain—the fans or blades being circular. 8th. In the event of a collision, the fans can be instantly set broad-side on, thus acting as a most powerful break, bringing the ship up on a few lengths. 9th. Its absence of all vibration and loss of steam-power, arising from the blades or fans being made quite *flat* and circular: it must be obvious that a curve or twist imparted to the blades will have two injurious results, viz., compressing and lifting instead of extruding the water off as it should in a direct line with the screw—it has an exuscitating tendency, hence loss of speed and steam-power unnecessarily absorbed. 10th. It dispenses with carrying a spare screw, duplicate blades only being required. 11th. It further dispenses with considerable expenses and loss of time which fixed screws entail, inasmuch as before the known pitch can be determined, the vessel has to make half a dozen voyages or more, and placed in dock as many times to take off and put on screws varying in pitch. With this invention, the right pitch can be ascertained in the run of a few miles.

FLEXIBLE SCREW PROPELLERS.

A PAPER was read on flexible screw propellers in the theatre of the United Service Institution, on Monday evening, May 30th, 1859, by James Reddie, Esq. (Captain J. G. Fishbourne, R.N., in the chair). After alluding to various inventions of paddle and screw propellers from 1690 and downwards, and mentioning that some recent successful experiments had been made by a Mr. Lochman with a new kind of screw propeller with blades peculiarly-shaped, being broader at the base than the ordinary screw, and with the corners always cut off, and which, from their construction, had the advantage of being made of wrought instead of cast metal; the lecturer proceeded to notice collapsing or duck's-foot propellers which had been tried with various modifications, but general similarity. The objection to these collapsing propellers is, that their action is not continuous, and the motion of the duck or swan, which they strive to imitate, is not sufficiently swift to render an imitation of it of any consequence. He then observed that as the problem was how best to produce a motive power in water, we should turn at once to the fish, and neither to aquatic birds nor amphibious animals, for an example of what we want. The action of a fish's tail has, indeed, been rudely imitated by the Indian with his canoe and paddle, by ourselves when one oar is used in the operation called sculling; and various ingenious, but necessarily complicated contrivances have been patented to produce the figure eight motion of sculling by machinery. Few, however, seem to have thought of imitating nature more closely by using a flexible propeller, which simply requires to be moved to and fro like the motion of a fish's tail. Something of this kind was patented by Durs Egg in 1815 for an aërial machine, but who also claimed the right of applying the invention to boats; in the following year, James Dawson obtained a patent for flexble paddle floats, flexible masts and sails, and a flexible lever or oar with a broad end formed of rods and elastic materials in imitation of a fish's tail; in 1824 William Busk obtained a patent for propelling vessels by a flexible steel plate applied like a rudder to a vessel, and to be moved either by hand or machinery; and lastly, so recent as 1854 the Earl of Aldborough had patented something of the kind, but chiefly for balloons.

It was to the probable afficiency of propellers something like those of Dawson and Busk that the lecturer wished to call attention; his only experiments had been tried with a home-made gutta percha propeller, much too slight for the boats to which it was attached, and which broke in consequence. The advantages he expects to gain from flexible or fish-tail propellers are their easy application to boats, in which, by crank machinery and multiplying power, one or two men in the stern of the boat could accomplish as much as eight or ten rowers; and boats so propelled could pass up narrow streams and creeks where oars could not be used. For war purposes boats so propelled would evidently have many advantages.

Digitized by Google

As regards their application to larger vessels to be moved by steam machinery, the promised advantages are an equally continuous power with that of the screw, and a power almost indefinitely increasing speed by means of a greater steam power, as those propellers would have no slip, and would not, like the screw, oppose any flat and resisting surface to be dragged through the water. For the same reason they would be found better auxiliaries to the use of sails, and when the vessel is moving under sails alone, would offer no obstructive surface as the screw does to the course of the vessel; they would also have immense steering power, and when a vessel is at rest, it could be moved round by a motion of the flexible propeller, which would at once put way on the vessel, and turn it if the motion were not reversed.

Although it could not be hoped that mechanical skill could succeed in producing such a perfect machine for strength and flexibility as a fish's tail, yet a ruder instrument might suffice when driven by means of the power of steam, which is far greater than the fish could exercise.

The lecturer concluded by showing that there was no presumption in thus supposing that science could emulate nature; science itself being only the application, and using the great powers of nature, such as fire and the expansive force of steam, by means of knowledge and art, and that thus it is that knowledge is power, true science being merely nature and art in harmonious co-operation.

FRENCH GUNBOATS.

THE gunboats are, with the exception of those in the outer harbour, undergoing alterations for their adaptation to a new system of naval warfare They are the Eclair, the Flamme, the Flèche, the Grenade, the Alerte, the Mutine, and the Tirailleuse. The first four are provided with engines of 110-horse power, and with two guns, 50-pounders. Only one of them, a three-masted fore and aft schooner rigged, can be compared with the English steam-gun sloops, of which the Coquette, that has been here, is a noble specimen. The French boat carries four 30-pounders amidships in addition to her two long guns forward; but, besides being inferior in engine power, her build and lines would lead one to believe that her speed must be greatly inferior to our steam sloops. The mode in which the heavy guns forward are mounted and are to be worked is a novelty. Whether it is likely to prove successful, naval men will be most competent to decide. During the Russian war the French gunboats that were sent into the Baltic were provided with moveable bulwarks, which, in action, were made to fall down and form an inclined plane, having on the exposed surface thick iron plates. The object of this arrangement was that if an enemy's shot struck the inclined surface it might receive an upward direction at a sufficient angle to pass over the guns and clear the ship. In the place of this arrangement, more ingenious than practical perhaps, a new system has been adopted. The stem and bulwarks are cut down level with the deck to a point just before the foremast. At this point a stout bulwark of oak is built across the deck from one side to the other and before the foremast. The bulwark is inclined backwards at a slight angle, and is to be faced with shotproof iron plates. It is pierced with two embrasures, circular-headed and straight-sided; and through these the guns are to be fired, the bowsprit being made movable to allow of it. From this arrangement it inevitably follows that the guns cannot be trained, the embrasures being much too narrow to allow it, and that they must be fired in a line with the ship's keel. The vessel would, consequently, be obliged in action to always present her bows to the enemy—that is, to offer the greatest facilities for being raked. Even if the iron-plated bulwark did prove an effectual shield, which may be doubted, the enemy's shot could penetrate other portions, and rake just the same. Moreover, suppose the shot struck the bulwark near the top, the inclination of its surface would carry the shot over, and land it probably among the machinery. The result would be the effectual disabling of the vessel until she has been refitted in a home port. It has been reserved for modern French naval artillerists to discover that the best position for fighting a ship is that in which she is exposed to be constantly raked.

The three last named gunboats—Alerte, Mutine, and Tirailleuse—are each fitted with one gun, 50-pounder, mounted on the same principle, the shield being lower, not much higher than a man's waist, and curved inwards. Their engines are 25-horse power for each boat. The floating batteries are much more formidable looking things, provided their crews are not stifled from the smoke of their own guns. I only counted nine ports on a broadside, but was informed that they carried 18 50-pounders, all of which could be fought on the same side. These floating batteries have a further arrangement which appears ingenious; they are provided with gratings outside the bulwarks, which can be let down so as to form a kind of balcony for riflemen to stand upon. Thus, supposing the battery to be fighting her port broadside, the balcony to starboard would be let down outside the bulwarks, and the riflemen who stood upon it would be protected by the whole breadth of the vessel.—*The Marseilles Correspondent of the "Times."*

EXPERIMENTS WITH SCREW PROPELLERS.

THE series of screw trials concluded by the Doris are the most important that have yet taken place since the introduction of the screw for the propulsion of our steamships of war. These trials were designed to test the relative qualities of the Admiralty or common screw and Griffiths's patent propeller. Similar trials were carried out in 1853, on board the Conflict and Fairy, resulting in favour of the Griffiths patent propeller, since which time the Griffiths has been constantly used by the Fairy when under way. The immense power of the engines now in use by our steam ships of war has given an opportunity of testing the merits of the two screws with the certainty of obtaining more practical results, more especially as affecting the vibration and steering of the ship than could be arrived at with vessels of the Conflict and Fairy's class; hence the present trials. The forms of the screws may be thus described:—The blades of the Admiralty screw consist of a sixth part of the whole screw or helix; the centre of the Griffiths propeller is a sphere of one-third the diameter of the screw, with the blades made tapering. The driving surface of the Admiralty lies at the extreme end of the blades; in the Griffiths it lies at the centre nearest the sphere. The first trial with the Admiralty screw was with a diameter of 18 feet, her speed being 11·823 knots. On the second trial, with the diameter increased to 20 feet, the speed realized was 11·826 knots, with a great increase of vibration. On the third trial the "leading" corner of each blade was cut off, and in this form the common screw attained its greatest speed, giving a result of 12,032 knots. On the fourth trial both the corners of each blade were cut off, when, with a greater number of revolutions, less speed was made, being 12 012 knots. Its last trial, with the "following" corner of each blade cut off, but the screw restored to its perfect form in every other respect, gave a result of 11·815 knots. The first trial with the Griffiths propeller—20 feet diameter and 32 feet pitch—gave 11·981 knots. The second trial, with a 26 feet 5 inch pitch, gave 12·269 knots; and the third trial, with a medium pitch, which concluded the series, gave 12·158 knots, with 53¾ revolutions of the engines, and less vibration than on any former trials. Several important features connected with the screw propeller have been proved by these trials. Firstly, that the leading edge of the screw is the part that mostly affects the steerage of the ship, and also causes the greater part of the vibration. Secondly, that increased diameter of the screw is better than increased pitch to reduce the speed of the engines, but it considerably increases the vibration with the common screw, whereas with the Griffiths it did not produce that effect, in consequence of its chief propelling surface being towards the centre. The common screw, when its blades are cut to the form of Griffiths's, is not so effective as when the centre sphere is applied to them; the power required to obtain the same speed is considerably reduced by its application. The power required to obtain 12 knots without the sphere was 2,920·32 indicated horse power, while the same form of blade and pitch with the sphere took only 2,825·6 indicated horse power.—The *Times* of June 6.

THE ROYAL MAIL STEAMER PARAMATTA.

OF the three monster steamships which the Royal Mail (West India) Company have just added to their fine fleet, the Paramatta is the first ready for sea, and is appointed to leave Southampton on the 17th inst. with the West India and Pacific mails of that date. The second, the Shannon, is rapidly fitting out on the Clyde; and the third, the Seine, was launched last week at Blackwall, from the premises of the Thames Iron Shipbuilding Company, where the Paramatta was also built. On Tuesday the Paramatta underwent her official trial, in the presence of the Government authorities, and the directors took advantage of the occasion to give a large number of persons the opportunity of witnessing for themselves the superior character of this noble vessel in regard to capacity, speed, and the general excellence of the arrangements for the purposes to which she is destined. She left the Southampton water about 11 o'clock on Tuesday morning for the measured mile in Stokes' Bay, with a party of nearly 200 on board. At the measured mile the Paramatta made four runs, with the following results:—

Runs.	Min.	Sec.	Average.	Runs.	Min.	Sec.	Average.
1	4	14	14·173	3	4	29	13·383
2	4	15	14·063	4	4	14	14·173

being an average of 13·956, or 14 knots per hour. Revolutions, 17½; pressure of steam, 17 lbs. to the square inch; vacuum gauge, 26½ inches. The following are her principal dimensions:—Length on the main deck, 340 feet; ditto load line, 330 feet; breadth, 43 feet 9 inches; ditto over paddles, 77 feet; depth of hold, from floor to spar deck, 33 feet 6 inches; horse power of engines, 800; builders' tonnage, 3,092; registered tonnage, 2,180; displacement at launching line, 2,215 tons. The engines are Maudslay and Field's patent double cylinder, taken from the Orinoco, and fitted to the Paramatta, with several improvements. The boilers have been made at the company's factory at Southampton, and are said to be the finest specimens of tubular boilers yet out, not being required to be proved a second time, the first proof being at double the pressure intended to be used. In fact, the steam generated was quite sufficient to drive engines with a third more pressure. The feathering paddlewheels were also made at the Southampton factory, and are beautiful pieces of workmanship. Attached to the engines are new pumps for filling the baths, hot and cold, at any hour of the day or night; and a constant supply of fresh water is insured by the application of Dr. Normandy's patent distilling apparatus, while the waste steam is received into iron tanks and condensed for washing and other purposes. The fire-extinguishing pipes (2½ inch) are at the command of any officer or engineer at all times, and can be turned on at a moment's notice to any or all of the compartments of the ship. The engines are also capable of pumping water out of any compartment at all times, or all compartments at the same time. The combined weight of the four boilers is 220 tons. The paddlewheels are 38 feet 6 inches diameter over the floats: diameter to the centre of pressure, 34 feet 3½ inches. There are 24 furnaces, and the ship has stowage capacity for 1,500 tons of coals. Great credit is due to the designer of the vessel, Mr. William Rennie, and also to Mr. Robert Ritchie, for the manner in which her machinery has been turned out of hand.

THE THRUST OF THE SCREW PROPELLER.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—Your remarks following my letter on page 363, call for a little further explanation from me.

Suppose a paddle-wheel steamer to have her old boilers removed, and to be supplied with new ones, and that such new boilers generate more steam

Digitized by Google

than the engines can consume, and it is not desired to increase the pressure. By reducing the surface of the paddle-boards, the engines may be made to work faster, thus using all the steam: the power and speed is thereby increased, yet the thrust of the paddle-shafts is not increased at all, the engines being incapable of increasing the thrust without increase of pressure. Now, if the thrust were measured by a dynamometer in each case, the result would be the same; yet, it is certain that the resistance is greater with the increased speed than before.

The same results would be obtained under similar circumstances with the screw propeller. Therefore, the thrust indicated by a dynamometer would not record the resistance encountered by the vessel.

I do not in the least question the law of equilibrium of forces; the *power* employed (after making the necessary deductions for friction, &c.) must be equal to the resistance. Nor do I attempt to frame a law upon the subject.

The pressure of a vessel's stem against the jetty when on trial in a wet dock depending on the nominal horse-power of the engines, leaves out of the question the boiler power, and is not a fair illustration, as I referred only to ships in motion.

Apologising for having occupied so much of your valuable space, I remain, Gentlemen,

Your very obedient servant,

T. MOY.

1 Clifford's Inn, June 6, 1859.

[Our correspondent's evasion of our reply to his last letter by saying that he referred only to ships in motion, affords us no encouragement to discuss the question with him further. Our inference was perfectly legitimate. If Mr. Moy believes that the speed of a screw ship moving under steam alone can be increased without an increase of the thrust upon the screw shaft, we can only regret the fact; argue the matter with him further we cannot. EDS. M. M.]

MARINE ENGINE-ROOM TELEGRAPHS.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—I have read with much surprise your article with reference to the trials of engine-room telegraphs for the navy at Sheerness, in your number of the 27th ult., wherein you make it appear that my telegraph is much inferior to either Suffield's or How's. I do not know who supplied you with that information, but the statements are entirely incorrect and contrary to the facts. I cannot state the number of "perfect" marks my telegraph, or any of the others registered, as I was not informed, nor do I believe either of the others were; but I *can* state that Mr. How's telegraph (the fourth put up by him in the same ship) was condemned *without undergoing a trial*, as I was at Sheerness when it was taken down. Consequently the statement with regard to Mr. How's is entirely untrue. And Mr. Suffield's is still incomplete, although it has been in hand since last June; and he has made several alterations since the trial took place in December; that I commenced fixing mine in March last, completed it, and was tried, and reported upon the latter part of April, since which time I have not touched it, it being pronounced perfect. And I have sufficient proof that my telegraph was recommended to the Lords of the Admiralty as the most *effective* and *complete*, both as regards its performance and workmanship.

I trust to your sense of justice and truth to insert the above statement of facts, or a contradiction to your former statement, which is calculated to do me serious injury with those who do not know the real state of the case.

I am, Sir, your most obedient servant,

GEORGE HORNSEY.

Patentee of improved engine-room telegraphs.

Southampton, June 7th, 1859.

P.S.—I beg to refer you to Captain Halsted, who, I have no doubt, will certify to the truth of my statement if required.

[If Mr. Hornsey will favour us with anything more reliable than his own version of the "facts," we shall be happy to correct anything which may thus be proved to be wrong. But we possess such unquestionable authority for the statements made in our article that we cannot think of retracting any part of them without better grounds than the above letter furnishes. As to Mr. Hornsey's reference to Captain Halsted—which we fear must have been made without the authority of that able and judicious officer—we can only say that we certainly do not feel at liberty to trouble him upon the subject. —EDS. M.M.]

THE ARMSTRONG GUN.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—Although allusion has been made to my plans in your valuable Magazine, I have never written publicly on the subject.

My father has devoted half a century to naval and military improvements, and, while examining some of his plans in 1840, I invented among other forms of guns that known as the "Armstrong." I started from my own definition that "a *gun is a directing tube on a reactionary base*," and proceeded accordingly to close one end of my tube in various ways. I confine myself to the mode bearing on the question. My earliest plan was a solid screw; I then interposed a plate to prevent the screw from stripping, and soon perceived that time would be gained by continuing the chase through the screw. My built-up tube had a bore rifled to receive a compound projectile hooped with lead, and containing pellets travelling in hollow cylinders, to discharge it by the laws of motion; the new gun-carriages run on inclined planes, to check the recoil and facilitate running out.

For any one understanding the subject, this description is sufficiently minute to demonstrate the identity in principle and form. Some time since friends informed me my gun and shell were being adopted, and urged me to bestir myself. The first description I have seen is that lying before me in a London journal of May 12th, given by Sir William Armstrong himself at Newcastle, but my father not wishing to give me trouble, although he had been given the particulars of this gun in December, declined to describe it to me; although unknown to me at the time, he claimed the originality of the invention as mine, at the war department, and to His Royal Highness the Duke of Cambridge, with the request of the claim being duly recorded.

In the spring of 1854 my father and self appeared before the select committee of artillery officers at Woolwich; the strong objection to breech-loading and "built-up" guns completely paralyzed all further effort, and with unshaken confidence we fell back on the forms which have appeared in your publication.

If it is conventionally admitted that the first publisher is to be considered the inventor, the fact of our appearing before the committee by *official instructions* establishes my right to that title.

It may be asked why did we not patent? Because cannon and shell are not commodities in general demand, and if the Government arbiters would not adopt our plans, they were useless.

Sir William Armstrong will pardon my saying that, had we patented, his position would have been secondary.

As the original inventor (in 1840) I appeal to the public sense of "fair play," and have the honour to subscribe myself, Gentlemen,

Your most obedient servant,

H. H. DRAKE.

Sedrah House, St. Austell, June 1st, 1859.

The new members appointed to serve on the Royal Ordnance Select Committee assembled in their office, in Woolwich Arsenal, on Friday, and concluded their arrangements for transacting the business of the department, which is henceforth to be distinct from and unconnected with any other department, nor is it intended, according to present stipulations, that any of the members shall reside in the Arsenal. By a memorandum from the Horse Guards, dated June 2, the members composing the committee approved by the Secretary of State for War, on the recommendation of the General Commanding-in-Chief, are as follows:—President, Col. St. George, C.B., Royal Artillery; and the members, Lieut.-Col. and Brevet-Col. Robinson, Royal Engineers; Lieut.-Col. and Brevet-Col. Greathead, C.B., 8th Foot; and Lieut.-Col. W. J. Smythe, Royal Artillery. Col. Pickering, who has been attached for some years past to the committee as secretary, has received permission to retire, and, as stated, will be succeeded by Lieut.-Col. J. H. Lefroy, Royal Artillery.

NOTICES.

The MECHANICS' MAGAZINE will be sent free by post to all subscribers of £1 1s. 8d., annually, *payable in advance*. Post Office Orders to be made payable to R. A. Brooman, at the Post Office, Fleet Street, London, E.C.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 5d. per line for any number of insertions less than 13; for 13 insertions, 4d. per line; and or 52 insertions, 3d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

Special Arrangements for larger or Serial Advertisements. To ensure insertion, Advertisements must reach the Office by 5 o'clock on Thursday evening each week. None can be received after that time for the ensuing number.

Our Weekly Gossip.

The following is a copy of the certificate of her Majesty's principal Secretary of State for the War Department, authorising the suppression of Sir William Armstrong's patent for his celebrated gun:—"In the matter of an Act to Amend the Law concerning Patents for Inventions with respect to Inventions for Improvements in Instruments and Munitions of War, 22nd Vic., cap. 14. And in the matter of William George Armstrong's patent, No. 2,564, I, the Right Honourable Jonathan Peel, Her Majesty's principal Secretary of State for the War Department, certify that William George Armstrong has made an assignment to Her Majesty's said principal Secretary of State of all benefit of his invention described in and by a provisional specification bearing date the fifteenth day of November, one thousand eight hundred and fifty-eight, and numbered 2,564, and of all letters patent to be obtained for the same. And I further certify that I think it for the benefit of the public service that the particulars of the invention, and of the manner in which the same is performed, should be kept secret. Dated this twelfth day of May, one thousand eight hundred and fifty-nine. (Signed) JONATHAN PEEL. (Witness) CHARLES M. CLODE, Solicitor to the War Department. To the Commissioners of Patents for Inventions."

By the end of July, or early in August, the different French navy yards will have completed, it is said, 120 flat-bottomed gunboats, small model, having fitted each with a 5-horse power steam engine and with one of the rifled four-pounders. They are intended to act on the Adda, the Mincio, and the Adige. By the same period will be completed 40 steam transports, capable of conveying 1,000 men each, besides the crew and baggage.

At the conclusion of the last screw-propeller trial on board the Doris the two systems of boat-lowering invented by Mr. Clifford and Captain Kynaston were displayed, the ship going about six knots. "Captain Kynaston's disengaging hooks appear to require four men for the operation," says the *Times* correspondent, "the success of which depends on the simultaneous working of the men. By Clifford's method the whole appeared to be more safely performed by one man, who by slacking off a rope insures the boat being lowered on an even keel." We do not understand why Captain Kynaston's apparatus should require four men to work it during the act of lowering. The gentleman who reported the trial of the Paramatta mail steamer for the *Times* says that at two different periods of the day Clifford's patent boat-lowering apparatus was put to the test. "The first time the steamer was going at 12 knots, when Captain Andrews, one of the Royal Mail Company's oldest commanders, now retired, volunteered; and on the second lowering she was going 14 knots, when Captain Andrews again volunteered, accompanied by Captain Mangles, Mr. Greenwood, and Mr. Alderman Rose, the boat descending to the water amid the loud cheers of the company on deck. Three or four ladies wished to accompany them, but it was not considered advisable. Each time the superiority of the invention was clearly demonstrated, and several gentlemen connected with the navy and mercantile marine who were present stated that they had always previously entertained great doubts about the system, but were now fully convinced of its safety and efficiency."

"Queer Astronomy" is the heading of a letter which Mr. J. Simon Holland, of Woolwich, sends us on a question of some importance. He says:—"If it be the purpose of the MECHANICS' MAGAZINE to prevent people being misinformed, as well as to inform them respecting mechanical laws, you will readily give a place to the following quotation from the article on astronomy in the Messrs. Chambers' 'Information for the People.' 'It might be supposed that, when the planet came to the part of its course where it is nearest to the sun, the attractive force

Digitized by Google

would be greater, and that some derangement might take place. But this is not the case. At that part of the course the planet moves faster than elsewhere, and thus baffles the greater attractive force. This phenomenon is particularly apparent in comets which have so eccentric an orbit. These bodies move with inconceivably greater speed when near the sun than in the remote parts of their orbits. It was a discovery of the German astronomer Kepler, in the seventeenth century, that, *notwithstanding the increased speed, a revolving orb goes over exactly the same amount of its circuit as when it moves more slowly.* Suppose a multitude of lines radiating from the sun, at equal distances from each other, the orb would be found to cross from one to another of these in exactly the same time, when it was *farthest* from the sun as when it was *nearest*. In scientific language, it describes equal areas in equal times.' The first words in italics were not so in the original, the latter two were. It would be difficult indeed to find in the whole range of scientific literature anything more thoroughly absurd and contradictory than the above most abortive attempt to describe Kepler's second law, the beauty of which has been supposed to consist to a great extent in its simplicity. But it appears that after all, it is not so simple that it can be readily understood by all who read it. As nearly seventy thousand copies of the article were sold the first year, it might be that some of your readers have been mystified by it, and that a line or two of explanation may be acceptable. If we imagine a line to be drawn from the sun to a planet, and to accompany it during its revolution in its orbit, lengthening and shortening as the planet increases and diminishes its distance from the sun, then will that line sweep over equal areas in equal times. When the planet is farthest from the sun, and is therefore moving slowest, the increased length of the line compensates for the diminished velocity of the planet. This line is called the planet's 'radius vector.' It is astonishing how the writer of the article could fail to understand such a simple law, and still more astonishing that he should not have seen the contradictory nature of what he was writing. If the multitude of lines he speaks of were at an equal angular distance, then must the planet have moved fastest when farthest from the sun, which was contrary to what he had just written; and if their extremities were at an equal distance, measured along the orbit, then must the planet have moved at the same velocity in all parts of its orbit, which involved another contradiction. The sentence marked in italics is not only contradictory, but unmatchably absurd. In the life of Capt. Cook, published by the same respectable firm, we are told that Cook went to the southern hemisphere to observe the transit of Venus *because* it could only be observed in that hemisphere, which betrays a culpable ignorance of the A B C of astronomy in one who undertakes to be a public instructor. I send you these two examples because the Messrs. Chambers, who have been eminently useful in the cause of public instruction, are now publishing another encyclopædia, in which accuracy is much to be desired; and also because a private remonstrance has been thrown away upon them. Blunders by minor men are not of so much importance."

Captain Molyneux Shuldham, R.N., writes from the Manor House, Dursley, Gloucestershire, under date of 6th June, 1859, respecting Mr. Novello's "craft," as follows:—"Had I not obtained experimental proof of the worthlessness of any plans having for their object the realizing greater speed from the revolution of buoyant wheels upon the surface of the water than of bodies passing through it, I should not ask you to encumber your pages with a comment upon an invention which can never be brought to any practical useful purpose, although I, who say so, may perhaps be the father of it, as I invented what I termed a sea-coach as far back as the year 1815. It consisted of four large drums with their axles running in frames, leaving a clear passage amidships the entire length of the coach between the wheels; of course, segments of the circumference of the wheels were immersed. I tried her first with a large square sail right before the wind, having set a small jib at the extreme end of the bowsprit to keep her from "broaching to." I selected a suitable pond for the experiment, and when there was a fine breeze upon it, I launched her; but, to my surprise, and, I may add, my *then* disappointment, the wheels refused to revolve at all, notwithstanding she made good way, at least as much as a boat would do with equal immersion. Determined to make the obstinate wheels revolve, I fixed small paddle floats to their sides, but not deeper than the immersed segments, but enough to force them to revolve. I made a second experiment, which turned out a very funny one; for when she had finished her voyage across the pond, and reached the opposite shore, which happened to be very flat, she did not stop, but continued sailing on the land, until some obstacle brought her up; so the sea-coach did very well *pour rire*, and nothing else, for I never could discover its application to any practical use, with the solitary exception that a horse or a donkey might be taught to do the duty of a waterman by being placed in a large drum (fitted with paddles) to turn it like a squirrel in its cage, or like a dog turning a spit. The axis of the drum should turn in a frame, like that of a rolling stone, placed before the drum, at the extreme end of which should be a buoyant large rudder capable of supporting one or two persons; by the use of such an amphibious machine, a gentleman who could afford to keep a horse or donkey, but not a yacht, could convert either of them into a waterman, and be propelled from his own door to the waterside, and launched without any manual labour, and go a long distance up or down a river, or out to sea in fine weather without any trouble than that of steering the amphibious animal. Here is no question of speed but economy, and the saving of manual labour. I read with surprise the numbers to which you allude contained in the 59th Volume of your Magazine, in which the inventor writes so enthusiastically in favour of the rolling-on-water plan; ill health prevented me at the time from writing an article upon it for insertion in your valuable Magazine. As the late Admiral Sir Sidney Smith had been ordered by his late Majesty to superintend a public trial of my revolving masts at Brighton, I had the opportunity of the honour of making his acquaintance, and to be invited to pass a whole day with him at his lodgings at Brighton, and, by way of passing the time and affording some amusement, I showed him a little sketch-book which contained some original ideas of mine, good and bad, of various inventions, my sea-coach being amongst the latter number, to which, however, he took a great fancy, and wished to combine it with my revolving mast. I, therefore, made every endeavour to prove to him that my sea-coach was a mere toy, and unworthy of the slightest notice or encouragement whatever. However, Sir Sidney made some boat experiments, the object being superior speed, but I have never been able to learn the nature of them. If the ocean from Galway to New York were imagined to be of ice, or a hard level road, the experience which I have had in sailing upon land would fully prove to my mind that no body (the balloon excepted) propelled by wind would equal the velocity of a land-boat on a large scale, nor any that would surpass a locomotive. I hope that the experiment which I have explained has made it quite clear that the immersed segments of drum water-wheels are *dragged through the water*, whether they revolve or not, consequently that no advantage is gained by their revolutions; it is only when their weight, together with the machine to which they are attached, is prevented from sinking by rolling upon a hard level surface that would realize all the striking advantages claimed by the inventors of rolling-on-water machines."

Patents for Inventions.

PROVISIONAL PROTECTIONS.

Dated April 30, 1859.

1088. A. McKechnie, of Carron, N.B., Engineer. Improvements in hammers and in apparatus for working the same.

Dated May 5, 1859.

1129. E. T. Hughes, of Chancery-lane. Improvements in the manufacture of sheet iron. A communication from D. A. Morris.

Dated May 6, 1859.

1142. T. Jones, of Liverpool, Slater. An improved apparatus and arrangement of flues for heating and ventilating buildings, ships, and other structures, and for causing draughts in chimneys.

Dated May 9, 1859.

1160. F. V. Hadlow, of Brighton, Engraver. An improved stamp for marking linen and other wearing apparel.

1162. A. V. Newton, of Chancery-lane. An improved construction of lamp. A communication from W. H. Racey.

1164. E. T. Hughes, of Chancery-lane. Improvements in obtaining motive power. A communication from A. F. Lapène.

1166. N. Barker, of Heyford, and J. A. Carter, of Blisworth. Improvements in apparatus for lubricating the pistons of steam-engines.

Dated May 10, 1859.

1168. R. J. Lees, of Woolley Bridge, near Hadfield, Derby. Improvements in steam generators or boilers.

1170. M. Defries, of Houndsditch, Manufacturer. Improved apparatus for regulating the pressure of gas.

1172. R. Thompson, of Glasgow, Manager. Improvements in shuttles.

1174. M. Henry, of Fleet-street. Improvements in heating and in supplying air, and in the apparatus employed therein, part of which improvements is also applicable to exhausting fluids. A communication from L. C. Bureau.

Dated May 11, 1859.

1178. A. Manbré, of Rathbone-place, Brewer. An improved method of extracting and purifying sugar, called glucose and "sirop de fecule," from potatoes or fecula, or starch or dextrine for the purposes and uses of brewers, distillers, vinegar makers, colouring makers, or otherwise.

1180. T. P. Bennett, of Gilnow Mills, near Bolton-le-Moors, Manager. Certain improvements in or applicable to carding engines.

1182. H. Clarke, of Wakefield, Corn Factor. Improvements in balancing millstones to the running as well as the standing state. A communication from T. Narburgh.

1184. C. F. Vasserot, of Essex-street, Strand. An improved musrol or noseband for horses' bridles. A communication from L. Marque.

1186. W. Salter, jun., of Lea, Wilts. Improvements in hay-making machines.

1188. J. B. Lyall, of Castle Frome, Hereford, Gentleman, and F. W. Campin, of the Strand. Improvements in the "Saloon" Omnibus and other omnibuses, the wheels and springs whereof, and mode of attaching them, being applicable to other carriages.

Dated May 12, 1859.

1190. J. Saxby, of Brighton, Engineer. Improvements in the mode of securing the rails on railways.

1191. R. A. Brooman, of 166 Fleet-st., London, Editor of the MECHANICS' MAGAZINE, and Patent Agent. Improvements in machinery for solidifying, pressing, and moulding. A communication from F. Dehaynin.

1192. A. P. Rochette, of Brighouse, York. An improvement in the manufacture of soft soap.

Dated May 13, 1859.

1196. T. Scott, of Rouen, Engineer. An improved surface condenser and refrigerator.

1198. J. F. Allender and J. Richards, jun., of Brierley-hill, Stafford, Managers of works. Improvements in furnaces for puddling iron.

1200. R. Gourlay, of Glasgow, Ironfounder. Improvements in making moulds for casting.

1202. R. A. Brooman, of 166 Fleet-st., London, Patent Agent. Improvements in cooking, preserving, and drying animal and vegetable substances. A communication from A. Bourdin.

1204. W. S. Thomson, of New York, Skirt Manufacturer. Improvements in the manufacture of hooped skirts. Partly a communication from W. Wilmot.

1206. G. R. Clover, of Liverpool, Ship Builder. Improvements in ships' night signals.

Dated May 14, 1859.

1208. M Leahy, of Hereford-road, Westbourne Park, Civil Engineer. Improvements in apparatus for facilitating the draught of carriages.

1210. D. Smith, of Glasgow, Civil Engineer. Improvements in projectiles for fire-arms.

1212. E. Maw, of the Doncaster Iron Works, York-shire. Improvements in the construction of buildings made of iron or other metals.

Dated May 16, 1859.

1214. S. C. Sheard, Engineer, of Smethwick, Stafford. Certain improvements in fire-bars, which bars are applicable to all furnaces where great heat and economy of fuel are required.

1216. W. Midworth, of Newark-on-Trent, Engineer. An improved iron for the use of laundries, tailors, or other purposes.

1218. J. Clark, of Glasgow, Wholesale Stationer. Improvements in envelopes, and in machinery or apparatus for gumming, embossing, folding, counting, and otherwise treating the same, and in part applicable in the treatment of note and other writing paper.

1220. W. E. Gedge, of Wellington-street, Strand. Improvements in mixing, combining, and otherwise treating certain matters and substances for the production of manure. A communication from L. Parent.

Dated May 17, 1859.

1222. L. D. Owen, of Tottenham-court-road, Engineer. An improved menstrual receiver or truss. A communication from H. W. Ladd.

1223. J. Brown, jun., of Rotherham, Ironfounder. Improvements in buffers, draw springs, and bearing-springs.

1224. A. R. Landre, P. Gras, and A. L. A. Boucherie, of Marseilles, Merchants. Distilling schist or bogheud coal and other minerals for lighting.

1225. H. Dolley, of Paris, Manufacturer. An improvement in the manufacture of hooped petticoats and in the metal ribs employed in the manufacture of hooped petticoats.

1226. A. E. C. J. Reynaud de Trets, of Marseilles, Gentleman. An improved composition for splitting rock.

1227. J. Nasmyth, of Surrey-street, Strand, Engineer. Improved apparatus for obtaining and applying motive power.

1228. C. Law, of Wolverhampton, Lockmaker. Improvements in the construction of locks.

Dated May 18, 1859.

1229. R. Romaine, of Chapel-st., Bedford-row, Gentleman. Improvements in the means of applying steam power to the cultivation of the soil.

1231. E. Charlesworth, of York. Counteracting the recoil of small fire-arms, and lessening the risk of injury arising from the bursting of the same.

1232. S. N. Evans, of Wolverhampton, Commission Agent. Improved mechanism for preventing accidents at mines from overwinding.

1233. J. Haslam, of Preston. An improved construction of healds or harness used in warp dressing and sizeing machines, and in looms for weaving.

Digitized by Google

1235. J. Dean, Cotton Manufacturer, J. Parkinson, Manager, E. Riley, Overlooker, and W. Burton, Mechanic, all of Haslingden, Lancaster. Improvements in certain self-acting mules for spinning fibrous materials.

1236. W. Nicholls, of Truro, Millwright. Improvements in portable corn mills.

1237. J. H. Johnson, of Lincoln's-inn-fields. Improvements in lubricating certain portions of machinery. A communication from M. Bonière, jun.

1238. R. A. Brooman, of 166 Fleet-street, London, Patent Agent. Improvements in heating. A communication from S. Lebobe.

1239. J. Childs, of Putney. Improvements in hardening and vulcanizing compounds of sulphur with india-rubber and gutta-percha.

Dated May 20, 1859.

1240. J. Valda, of London. Improvements in stud-fastenings, and a system of ornamenting and adapting belts, cravats, ribbons, draperies, and other articles to stud-fastenings.

1241. G. Walker, of Shoreditch. Certain improvements in swing looking-glasses.

1242. R. Wilson, of Patricroft, Engineer. Improvements in hydraulic machinery.

1243. H. Newman, of Liverpool, Dentist. Improvements in the construction of artificial teeth, and in the mode or manner of affixing the same to the frame.

1245. R. V. Leach, of Taibach, Glamorgan, Tin Plate Manufacturer. Improvements in the manufacture of iron, and in the machinery connected therewith.

1246. D. Kirkaldy, of Glasgow, Engineer. Improvements in the manufacture or treatment of steel.

1247. J. H. Johnson, of Lincoln's-inn-fields. Improvements in the roasting or calcining of ores, applicable also to the oxidising of other substances. A communication from J. F. Persoz.

1248. W. Teasdel, of Great Yarmouth, Engineer. Improvements in coffer dams.

1250. J. P. Budd, of Ystalyfera, near Swansea. Improvements in the manufacture of tin and terne plates.

1251. W. C. Cambridge, of Bristol, Agricultural Implement Maker. Improvements in thrashing and winnowing machines.

Dated May 21, 1859.

1253. J. R. Scartliff, of Wolverhampton, Mechanic. Improvements in the construction of lubricating and other cans in order to regulate the discharge or flow of the liquids they contain.

1254. J. Thompson, of Witton, near Northwich, Cheshire, and J. Thompson, jun., of Northwich. The manufacture of salt by an improved and more economical mode.

1255. A. V. Newton, of Chancery-lane. An improved construction of cartridge. A communication from T. F. Henderson.

1256. W. P. Savage, of Roxham, Norfolk. Improvements in traction steam-engines and machinery for moving agricultural implements and machines.

1257. W. H. Perkin, of St. George-in-the-East, and M. Gray, of Bonhill, Dumbarton. Improvements in mordanting and dyeing fabrics of cotton and other vegetable fibres.

Dated May 23, 1859.

1261. J. Knowles, of Lower Broughton, near Manchester, Machinist. Certain improvements in power looms for weaving.

1263. W. Crum, of Thornliebank, Renfrew, Bleacher. Improvements in printing and dyeing textile fibres and fabrics.

1265. J. H. Mason, of Nottingham, Lace Manufacturer, and G. L. Baxter, of Nottingham, Dyer. Ornamenting lace or other twisted fabrics.

1267. J. L. Jullion, Paper Maker, of Aberdeen. Improvements in dressing and finishing textile fabrics.

1269. R. A. Brooman, of 166 Fleet-st., London, Editor of the MECHANICS' MAGAZINE, and Patent Agent. Improvements in axles, and in fitting wheels thereto. A communication from M. Masson.

1271. W. Clark, of Greenock, Marine Painter. Improvements in machinery or apparatus for propelling and manœuvring ships, vessels, and boats.

1273. A. Barclay, of Kilmarnock, Engineer. Improvements in steam hammers.

1275. A. V. Newton, of Chancery-lane. An improved construction of washing machine. A communication from D. Parker.

Dated May 24, 1859.

1277. G. Davies, of Serle-st., Lincoln's-inn. Atmospheric apparatus for the submarine transport of blocks of stone, and for raising sunken vessels. A communication from T. Bandier.

1279. G. D. Jones, of Clerkenwell, Engineer. Improvements in mills or machinery for grinding, reducing, and pulverizing.

1281. W. T. Denham, of Wilmington-sq., Trimming Manufacturer. Improvements in the manufacture of goffering machines.

1283. E. Page, of Bedford, Agricultural Implement Manufacturer. Improvements in horse drags or rakes.

1285. B. F. Greenough, of Boston, U.S. An electrical conductor for submarine telegraphs, which he denominates a hydro-electric conductor.

Dated May 25, 1859.

1287. J. Harmer, of St. James-st., Islington. Improvements in parts of dry gas-meters. Partly a communication from W. Sinderby.

1289. R. A. Glass, of Leadenhall-st., Submarine Telegraph Cable and Wire Rope Manufacturer. Improvements in submarine electric telegraph cables.

1291. A. Prince, of Trafalgar-sq. Improvements in the construction of ships and vessels. A communication from H. Hirsch.

1293. A. J. Davis, of George-st., Hanover-sq., Surgeon Dentist. Improvements in apparatus for protecting persons when employed in cleaning windows, painting, or working at the exterior of houses and ships' sides, and such like operations, applicable also for purposes of military and other observation.

1295. A. V. Newton, of Chancery-lane. Improved machinery applicable to the manufacture of rivets, bullets, and other like articles. A communication from C. B. Allen.

1297. C. E. Amos, of the Grove, Southwark, Engineer. Improved apparatus for raising vessels for repair, and for floating vessels in shallow water.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(*From the London Gazette, June* 7, 1859.)

214. J. and W. H. Smith. Paper.
215. J. Savory. Bottles.
244. W. Ager. Cleaning rice.
245. T. Hartshorne. Metal.
246. E. Dixon and H. Whittaker. Weaving.
255. I. Zacheroni. Preventing smoke.
256. W. Robertson. Propelling boats.
259. P. Prince. Breech-loading gun.
272. T. P. Smith. Guiding the pen or pencil.
274. J. Raywood. Sewing machines.
276. J. Robertson. Motive force.
283. S. B. Everleigh. Hats.
297. E. Wilkins. Drain pipes and tiles.
301. S. Tearne. Ornamenting surfaces.
307. T. Storer. Funeral carriage.
330. W. Clark. Preserving grain, &c. A communication.
335. T. and B. C. Sykes. Separating oily and resinous substances from seeds, &c.
336. T. R. Ayerst. Fire-arms. A communication.
347. J. Wilson. Ventilating mines.
349. E. T. Hughes. Sorting threads. A communication.
359. T. S. Cressey. Casks.
431. W. E. Newton. Mowing machine. A communication.
499. J. Robinson. Spinning and doubling.
511. T. C. and G. J. Hinde. Coating iron.
556. W. E. Newton. Barometers. A communication.
702. J. Howden and A. Morton. Motive power.
896. T. Spencer. Treating refuse containing sulphur.
927. J. Apperly and W. Clissold. Fulling machine.
978. J. and H. S. Morton. Ash-pans.
998. J. Apperly and W. Clissold. Oiling wool.
1004. J. Davies. Ringing door bells.
1055. H. R. Fanshawe. Drawing-off liquids, &c.
1132. R. A. Brooman. Fire-arms, projectiles, wads, and cartridges. A communication.
1160. P. V. Hadlow. Stamp for marking linen.
1163. A. Morton. Weaving figured fabrics.
1171. J. Norman. Furnaces.
1172. R. Thomson. Shuttles.
1201. T. Vicars, sen., T. Vicars, jun., T. Ashmore, and J. Smith. Bread, biscuits, &c.
1216. W. Midworth. Iron for laundries.
1218. J. Clark. Envelopes and paper.
1226. A. E. C. J. Reynaud de Trets. Splitting rock.
1228. C. Law. Locks.
1249. G. R. Sampson. Propelling. A communication.
1265. J. H. Mason and G. L. Baxter. Ornamenting fabrics.
1273. A. Barclay. Steam hammers.
1289. R. A. Glass. Telegraph cables.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed June 2, 1859.

2556. D. Frodsham.
2774. J. B. and J. Fisher and J. Bird, jun.
2781. H. T. Yates.
2793. D. B. White.
2794. R. A. Brooman.
2808. J. Ferrabee and F. H. England.
2847. M. Schaffner.
2856. R. A. Brooman.
2858. J. Ferrabee.
2870. F. C. N. J. Viellard-Migeon.
2904. E. Weber.
2963. H. Lowe, W. Trueman, and J. L. Pitts.
59. W. E. Newton.
153. R. Garrett, jun., and J. Kerridge.
177. W. E. Newton.
463. S. Wheateroft.
654. B. Rider.
734. J. Macintosh and G. Rhodes.

Sealed June 7, 1859.

2797. J. E. Boyd.
2810. G. F. Chantrell.
2815. A. Lamb and W. A. Summers.
2819. R. L. Burrowes and J. Knowles, jun.
2820. J. Barrow, jun.
2822. J. Eccles.
2825. J. Elder.
2826. J. Stewart.
2827. T. Allen.
2829. H. Wilson.
2830. E. L. Pen-uetc.
2843. S. Dadgeon.
2869. H. Bridges.
13. W. Eccles.
104. C. N. May.
159. W. A. F. Powell.
647. T. Patstone.

PATENTS ON WHICH THE THIRD YEAR'S STAMP DUTY HAS BEEN PAID.

1298. T. Wilson.
1314. G. J. Mackelcan.
1333. D. Morrison.
1363. C. W. Siemens.
1419. W. H. Barlow and W. H. Woodhouse.
1424. J. Davis.
1531. E. Rogers and H. Mackworth.

LIST OF SPECIFICATIONS, &c.,

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement :—

STEAM ENGINES, &c., 2474, 2482.
BOILERS AND THEIR FURNACES, 2470, 2488, 2517.
ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 2447, 2461, 2484, 2504, 2516.
SHIPS AND BOATS, including their fittings, 2442, 2444, 2479, 2483, 2495, 2496, 2502, 2507, 2519.
CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 2451, 2458, 2462, 2498, 2503.
FOOD AND BEVERAGES, including apparatus for preparing food for men and animals. *None.*
FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 2450, 2456, 2457, 2460, 2465, 2466, 2475, 2490, 2493, 2501, 2505, 2509.
BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c., 2448, 2494, 2512.
LIGHTING, HEATING, AND VENTILATING. *None.*
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 2446, 2453, 2454, 2469, 2276, 2492, 2499, 2508.
METALS, including apparatus for their manufacture. *None.*
CHEMISTRY AND PHOTOGRAPHY, 2487, 2513.
ELECTRICAL APPARATUS, 2445, 2468, 2514, 2515.
WARFARE, 2444, 2459, 2463, 2473, 2497.
LETTER PRESS PRINTING &c. *None.*
MISCELLANEOUS, 2443, 2449, 2452, 2455, 2464, 2467, 2471, 2472, 2477, 2478, 2481, 2485, 2486, 2489, 2491, 2500, 2506, 2510, 2541, 2518, 2520.

2442. R. C. SMITH. *A new or improved buoy or wreck intelligencer.* Dated November 2, 1858.

The patentee describes a buoy or wreck intelligencer constructed of a hollow sphere or other shaped vessel of copper or other material, which vessel may either separate in two parts or have an opening in the upper part, the opening being closed by a lid; the said buoy being surmounted by a reflecting sphere, or reflecting planes, or both, and so loaded that in floating that part of the buoy carrying the reflecting surfaces shall always be uppermost. *Patent completed.*

2443. J. LANCASTER. *A new or improved method of driving and curbing horses.* Dated November 2, 1858.

This consists of machinery fixed to the foot-board of carriages, &c., for holding the reins, and when pulled tight permanently keeping them so as required. *Patent abandoned.*

2444. M. L. J. LAVATER. *Improvements in cartridges for military and other purposes.* Dated Nov. 2, 1858.

Here the case of the cartridge is formed of vulcanized india-rubber, and is of a cylindrical form, closed at one end and open at the other. The closed end is made to a semi-circular, or other form, to fit the front part of the ball; and the mouth, or other end of the case, is contracted, or is of less diameter than the cylindrical portion of the case. In filling this case, its mouth is stretched over the end of a funnel so as to bring the opening to the same size as the interior of the cylinder, and the ball is then rammed in, and a wad rammed down over it; the measure of powder is then poured in on the top of the ball, or on the wad, and lastly, a plug of earthenware, wood, or metal is rammed in on the top of the powder, and when the mouth of the case is taken off the funnel it springs over the plug and holds it in its place; the cartridge is then hermetically sealed. In the top of this plug a hole is formed to receive the cap, which is thus held ready for use. In loading with this cartridge, the cap is first put on the nipple, the cartridge, as will be understood, serving as a handle for the cap during this operation; then by pinching the end of the cartridge the plug is forced out and the powder is poured into the barrel; lastly, the ball (or shot) is rammed down on to the powder together with the case, which serves as a wad. *Patent abandoned.*

2445. A. BARCLAY. *Certain improvements in electric and magnetic or electro-magnetic telegraphs applicable to submarine and land communication.* Dated Nov. 2, 1858.

This consists in laying conducting wires of different

Digitized by Google

metals and of the same metal from both ends as poles of the galvanic batteries, so as to complete the circuit direct, and the said wires being made or not in one cable, but so insulated that the one cannot touch the other. It also consists in reversing the wires or poles of the batteries so as to give a reverse action to the current of electricity, and in the case of submarine telegraphs taking advantage of the sea to from part or whole of the batteries by making the conducting wires of different metals. And in the case of the present Atlantic cable, making use of the present outside covering wires as one of the said conducting wires or generating battery, and making use of positive and negative coils to strengthen the current of electricity on said wires. *Patent abandoned.*

2446. D. D. KYLE. *Improvements in boots and shoes.* Dated November 2, 1858.

This consists in adjusting boots to the instep by screws attached to, or inserted in the heels or soles, which screws are connected with the uppers or sides of the boots or shoes by thongs, straps, or wires, passing over or through pins, pulleys, or grooves in the heels or soles, thus communicating a tightening or loosening action or effect when the screws or apparatus are actuated or adjusted. *Patent abandoned.*

2447. J. SAMPSON, J. MACHON, and J. BARTHOLOMEW. *Improvements in railway carriage brakes.* Dated Nov. 2, 1858.

This consists in placing beneath the end of every carriage a horizontal steam cylinder with outlet at its upper end. This outlet communicates with a pipe running the entire length of the carriages, the connecting pipes between each carriage being made of any known elastic or pliable material. The piston rod is jointed to a connecting link which is also jointed to the end of a bell crank lever; this lever actuates the brake blocks. To put the brakes in action, the steam has to be turned on, when it will enter all the cylinders about the same time, driving the pistons back, by which means the brakes are applied to every carriage simultaneously. The train having come to a stand still, the guard can then blow off the steam by a cock at the outlet pipe, and allow the carriages to take a backward motion if necessary. *Patent abandoned.*

2448. A. MC DOUGALL. *Improvements in the construction of reservoirs, tanks, culverts, sea-walls, and other erections required to exclude water or damp.* Dated November 2, 1858.

This consists in the use of bricks or blocks made by combining asphalte or other bituminous matter with sand, gravel, or other grit. *Patent abandoned.*

2449. N. S. DODGE. *Improvements in treating waste vulcanised india-rubber.* A communication. Dated November 2, 1858.

This chiefly consists in restoring waste vulcanised india-rubber by submitting it to the action of heat, steam, or water; and in combining fibrous materials with such waste rubber. *Patent completed.*

2450. S. BOTTOMLEY. *Improvements in the manufacture of morcens and other fabrics of a similar character.* Dated November 3, 1858.

This consists in the use of weft composed of hemp, flax, linen, &c., in the manufacture of morcens. Also in the use of weft composed partly of wool and partly of hemp, flax, linen, &c. Also in the use of linen, flax, or hemp as weft threads in conjunction with worsted warp in the production of other fabrics wherein worsted wefts have hitherto been used. *Patent completed.*

2451. C. F. O. GLASSFORD. *Improvements in the manufacture of manure from the excreta of towns.* Dated Nov. 3, 1858.

This consists in applying sulphuric acid to neutralise the ammonial constituents of the collected excrementitious matters of towns, and in afterwards evaporating, pressing, and mixing, as may be required, the several products in any desired proportions to obtain different qualities of the same. *Patent abandoned.*

2452. H. TERTIAN-MORET. *The application of a mineral named Deterso, as a disinfecting, preserving, absorbing and curative power.* Dated Nov. 3, 1858.

The mode of preparing this powder is by placing it in a rather fierce furnace for a certain time, when it can be easily crushed into powder, after which it is passed through a fine sieve and is fit for use. *Patent abandoned.*

2453. V. BLUMBERG. *Improvements in the construction of slate billiard-tables, which improvements are also applicable for other useful purposes.* Dated Nov. 3, 1858.

The object here is to coat or veneer wood with slate so as to render the combination of slate and wood applicable for various purposes. The invention is primarily applied to billiard tables. *Patent completed.*

2454. J. TALL. *Improvements in brushes or brooms for sweeping floors, carpets, and other similar articles.* Dated Nov. 3, 1858.

This consists of a cylindrical brush, the shaft of which is connected by a band or by toothed gear with the action of a rolling cylinder, or pair of wheels, or rollers placed at its rear; a chamber with an opening in it is placed so that the opening is towards the brush; a pan or drawer is placed within this chamber, and the whole enclosed in a light cover leaving the bottom open; when urged forward by the handle the motion of the rollers is communicated to the brush. No dust, when using this brush, can fly about the room. *Patent abandoned.*

3455. D. FRYER, T. L. C. WATT, and W. HOLMES. *Improvements in tanning hides and skins.* Dated Nov. 3, 1858.

The patentees employ round upright tanks capable of bearing a pressure of from 10 pounds up to 120 pounds to the inch. These tanks are fitted internally with laths or hoops, upon which each skin is separately attached at its full length. A hydraulic pump is used for forcing the liquor into the tanks. The fitting with the skins should be moved about four times a day for the first three days; at the end of that time twice a day, and at the end of the fifth day once, when the tanning will be completed. *Patent completed.*

2456. P. A. MAWDSLEY. *Improved machinery or apparatus for drying yarns after being sized or stiffened, and the use or application of a certain substance or substances in the sizing, stiffening, or otherwise preparing yarns and woven fabrics, or either of them.* Dated Nov. 3, 1858.

This consists in furnishing one or more of the drying cylinders with projecting rods, bars, or blades of wood, iron, &c., placed longitudinally on the circumference of the cylinder, to prevent the yarn from coming in contact with such cylinder. Also in the use of alkaline aluminates, such as the aluminate of soda and the aluminate of potash for sizing, stiffening, or otherwise preparing yarns or woven fabrics. *Patent completed.*

2457. P. A. MAWDSLEY. *The use or application of a certain substance or substances in the manufacture, stiffening, or sizing of paper.* Dated Nov. 3, 1858.

This consists in employing for the sizeing of paper alkaline substances such as the aluminate of potash and the aluminate of soda, either separately or mixed with other preparations. *Patent completed.*

2458. J. FOWLER, jun., R. BURTON, and D. GRFIO. *Improvements in applying motive power to actuate ploughs and other agricultural implements.* Dated November 3, 1858.

This invention was described at page 321, No. 20 of the MECHANICS' MAGAZINE. (New Series.) *Patent completed*

2459. F. B. BUSSE. *Improvements in breech-loading fire-arms.* (A communication.) Dated Nov. 3, 1858.

The barrel of the arm is pivoted to the stock with a screw or bolt, which passes through a slot in a loop projecting from the under side of the barrel; this slot allows the barrel a slight longitudinal movement, at the same time that it oscillates a short distance vertically around the bolt. The breech-piece has a hole in its centre, and through this hole passes a pin by which the percussion cap in the cartridge is exploded. Attached to the breech-piece is a hollow conical thimble, which fits into a recess in the lower end of the barrel. When the barrel is in position for firing, this thimble is forced into the recess, the inner edge of which is turned down, so as to form a thin ring or cylinder that may expand against the thinner surface of the thimble by the force of the explosion, thus forming a tight joint and preventing the escape of gas. In the upper part of a tumbler, which is mounted on the hammer spindle, is a notch, which receives a pivot attached to the pin or needle bar; this bar, with the pin or needle, slides in a hollow guide bar, which is attached at one end to the breech-piece, and is slit lengthwise to accommodate the end of the tumbler. The rear end of the needle bar has also a slit in it, to accommodate the end of the tumbler, and a pivot passes through the needle bar across the slit, and fits in the notch in the tumbler. Thus, as the tumbler is thrown forward by the main spring when the trigger is pulled, it drives the needle bar in its guide bar in a line coincident with the axis of the barrel. The arrangement by which the rear end of the barrel is raised for loading, and by which it is returned to its place and there secured, and by which the gun is cocked is as follows:—The trigger guard is pivoted on the under side of the gun, and serves as a lever, and is moved laterally on its pivot. To the end of this lever is attached a pin, which passes up through the stock beneath the barrel, and secures at its end a disc or head. On the upper end of this disc rises an excentric cam, and near to it is a pivot, which stands up in the slot of the flat bar which slides in a recess in the stock beneath the barrel. The rear end of this bar passes through an opening in the breech-piece, and is bent up at right angles. When the lever or trigger guard is swung forwards, the disc is turned round, and the pivot forces back the flat bar, the bent portion of which presses against the front edge of the hammer tumbler, thereby forcing it back against the resistance of the main spring, and cocking the gun. As the movement of the lever or trigger guard is continued a little farther, a cam strikes against the corner of the notch of the barrel, and thus forces the barrel forward off from the thimble. When thus pushed forward, the weight of the muzzle overbalances that of the breech, and throws the barrel into the position ready for loading. When the cartridge has been inserted in the rear end of the barrel, and the trigger guard is brought into its place, the outer end of the flat bar strikes against a projection on the loop, and raises the muzzle of the barrel, and brings the breech down into the stock. When the trigger guard or lever is closed up to the stock, it is held in place by a stop attached to the stock, which fits into a notch near the end of the lever, and then the gun is ready for firing. Although the needle is intended to explode the cartridge by striking a percussion cap which is inserted into the conical ball of the cartridge, it is important to provide further means of explosion by the addition of a common nipple. This nipple may be used to advantage in the following instances:—1st, if the cap of the cartridge should miss it would be a loss of time to take the cartridge out again, a cap may be set on the nipple and the gun fired. 2nd, in cases of want of prepared ammunition with caps inserted in the balls, round balls and common ammunition may be used. 3rd, if any injury to the pin system should ever occur, the gun by the provision of the nipple will still be a useful gun. *Patent abandoned.*

2460. E. FIELDING. *An improved means of preserving the form of cops of yarn by the application of adhesive substances.* Dated November 4, 1858.

This consists in applying an adhesive substance to the lace spindle on which the yarn is wound, or in winding 3 or 4 layers of yarn on the bare spindle as usual, and then applying the adhesive substance which may be done by hand, or by self-acting machinery, while the spindles are revolving, and the machine continues its work until the cops are built. By the time the cops are complete the adhesive substance has become hard, thereby uniting the inner layers of yarn, forming the bottoms of the cops, the forms of which are thus preserved when the cops are doffed, and when putting them on to the skewers of the winding or doubling frame, or of the shuttles from which they are unwound with less waste than heretofore. *Patent completed.*

2461. J. OXLEY. *Improvements in carriages and wheel vehicles.* Dated Nov. 4, 1858.

This consists, 1, in constructing a two-wheeled carriage so that it may be used as a close or open carriage. 2. In introducing an elastic material between the shackles and other bearing, su-pending, and pulling parts of carriages between the body and under carriage of wheel vehicles. 3. In substituting for the ordinary kind of apparatus used for turning four-wheel carriages, a mechanical contrivance by which a vehicle may more easily than heretofore be turned in a much shorter space, whilst a greater angle may at the same time be made in less distance during the forward motion of a carriage allowing the centre or turning point to be brought much nearer to the hinder wheels than heretofore. *Patent completed.*

2462. C. F. VASSEROT. *Improved driving machinery applicable for thrashing grain and other agricultural purposes.* (A communication.) Dated Nov. 4, 1858.

This consists, 1, of a foundation plate of cast iron fixed upon a wooden frame 2. Of a large toothed wheel, the teeth of which are on its inner periphery Upon the wheel are fixed the shaft or poles by which the power is applied. 3. Of a pinion gearing with the main wheel above named. This pinion is cast of one piece with a toothed wheel to which it gives motion. This toothed wheel gears with a pinion placed upon a vertical axle passing through the centre of the foundation plate. A bevel wheel is placed at the lower end of the vertical axle, which gears with a pinion fixed upon a horizontal shaft, upon which is a rigger connected by an endless band to a small pulley placed upon the shaft of the thrashing cylinder or other machinery to be driven. *Patent abandoned.*

2463. G. P. EVELYN. *The improvement of the form of the stocks of rifles, carabines, and other fire-arms.* Dated Nov. 4, 1858.

Here, several advantages are attained by the peculiar form given to the but of the gun stock. The sole of this, when in position for taking aim, lies obliquely in respect to the man's shoulder, the toe passing underneath his armpit. It is called the "Under arm gun stock." *Patent completed.*

2464. J. R. NAPIER. *Improvements in obtaining motive power by means of heat.* Dated November 4, 1858.

This consists in the heating of the steam or other vapour or gas after it has been generated by subjecting it to the heating action of pipes through which currents of hot liquid circulate. *Patent abandoned.*

2465. C. MATHER. *Improvements in drying yarns while in the hank.* Dated Nov. 4, 1858.

Here hanks of yarn are made up into an endless chain, the hanks being attached end to end which, is done by using short rods of wood. The rods are held parallel to each other, and are attached at their ends in pairs by straps or loops, and in this form they are passed continuously through a stone, or over drying cylinders, &c. *Patent abandoned.*

2466. W. T. MARLEY. *Improvements in printing and dyeing woven fabrics.* (A communication.) Dated Nov. 4, 1858.

This relates to the "dunging" process, and consists in combining with the chemicals ordinarily used brewers' wort, or other saccharine matter; or an extract of Iceland moss, gum or other mucilaginous substance is employed. *Patent abandoned.*

2467. R. A. BROOMAN. *Improvements in treating air and gases, and the employment of the same for obtaining motive power.* (A communication.) Dated November 4, 1858.

The object here is to lessen the diameter of the pump of caloric engines by treating the air and other gas or gases so that its volume will be greatly increased when in contact with heated surfaces, over the same quantity when worked in its normal condition. The invention consists, 1, in saturating air or gas with water to its full capacity of retaining the fluid in a separate condition, previous to it contact with the heated surfaces. 2. In regulating the force developed by the admixture of dry air between the moistening apparatus and the air pump. 3. In constructing the heated surfaces in the form of a hollow ribbon concentrically coiled. 4. In overcoming the resistance arising from the lap of the valve employed in the pump by lever and cam motions. *Patent completed.*

2468. I. BAGGS. *Improvements in telegraphing by electricity.* Dated Nov. 4, 1858.

This consists in the use of a fixed microscope, telescope, or other optical power or instrument, in combination with an instrument or apparatus for indicating currents or effects produced in telegraphing by electricity; whether a needle instrument or an instrument in which movements are capable of being produced or exerted by electricity however obtained or applied, and whether the electricity be frictional, voltaic, or otherwise. The patentee prefers to use the chemical agency of electricity as acting upon particles of matter and not upon masses, and being thereby practically independent of the opposing forces of inertia and friction. The invention also consists in the generation of gas by electricity as aforesaid for telegraph purposes, under a vacuum or partial vacuum, with or without the application of the microscope, whereby the bubbles of gas are made to expand to two or three hundred times their ordinary size, and the indications are thus made more distinct. The invention further consists in the application of photography, conducted by any suitable means whatever, to impress upon paper, glass, or other material the required telegraphic communications. *Patent abandoned.*

2469. A. FRIEDMANN. *An improvement in bracelets, necklets, and rings.* Dated Nov. 4, 1858.

This consists of means of fastening and fixing the above mentioned articles on the wearer at the desired degree of tightness. The strap is first run through a slide or clip (one or more), from the centre of which there rises a threaded pin. A button or stud screws down upon the threaded pin and fixes the strap. *Patent abandoned.*

2470. W. H. TOOTH. *Improvements in the manufacture and construction of fire or furnace bars.* Dated Nov. 5, 1858.

The invehtor forms two or more longitudinal pieces similar in shape to an ordinary fire or furnace bar, and arranges them at suitable distances apart, having between them a number of cross pieces, so as to form a series of

Digitized by Google

air spaces. The whole is cast in one piece, and when finished the upper surface of the bar resembles a grating. *Patent abandoned.*

2471. T. TILL. *Improvements in machinery for making nails, and for other analogous purposes where metal is compressed by dies or stamps.* Dated Nov. 5, 1858.

This consists in constructing a machine so that a cam upon, or a crank in, a driving shaft, acting in its revolution upon a bar, moves or slides it lengthwise to and fro, and thus causes two headers placed one in each end of the bar to work alternately in making the heads to nails, &c., by compression, and so that a similar device upon the same shaft acting upon a series of levers connected to the movable holding and pointing die, the other being stationary, holds and points the nail just before the action of the heading die. The material may also be fed in by a third similar crank or cam motion on the said shaft, so that enough of the end for the head or part to be compressed is projected the proper distance beyond the holding dies at the right time for the header. *Patent completed.*

2472. T. B. SMITH. *Preparing wood so as to be used as a substitute for curled hair in the manufacture of mattresses, and in the other purposes to which curled air and its substitutes are applied.* Dated Nov. 5, 1858.

This consists in cutting hickory, poplar, cedar and other wood into thin elastic shavings, and dividing the shavings longitudinally, and coiling them so as to form compound shavings, and subjecting the same to the action of steam. *Patent completed.*

2473. C. J. TJADER. *Improvements in gun carriages, and in apparatus for lessening recoil.* Dated November 5, 1858.

Here the trunnions of the gun are placed in cast iron blocks running in grooves. Before and behind each trunnion a conical spring receives its respective portion of the recoil or counter recoil. The springs are compressed against the upright ends of the frame. Before and behind the carriage pivot a spring receives the secondary recoil and counter recoil. An arrangement of screws acting one within the other is used for the elevation of the gun, which runs upon a wheel at the top of the innermost of the screws. The inventor proposes also to place springs at the parts of a ships side where the breeching tackle of the gun is usually fastened. *Patent abandoned.*

2474. E. ROWLAND and J. DEWHURST. *Certain improvements in steam engines, and in the valves connected therewith, which said improvements in valves are also applicable to safety valves.* Dated Nov. 5, 1858.

Here the piston of a steam engine consists of a hollow ram oscillating upon a hollow bearing at a point situated about the middle of its length, and each end of this double piston works in a cylinder, both cylinders being furnished with a steam-tight packing through which the piston works. The extreme ends of each cylinder are connected to a crank upon the shaft to be driven. The hollow shaft or bearing upon which the piston oscillates may either be made to form a valve itself, or be furnished with a disc valve, so that the oscillating motion of the hollow piston shall open and close the slide valve. The steam is exhausted after each stroke from the side opposite to the supply pipe. In the improved throttle valve the valve is mounted loosely upon a central vertical spindle, the top of which is connected to the governor of the engine, and is also secured to a receiver which rises and falls in a tank of mercury, a second and similar arrangement being placed beneath the valve, so that the whole weight of the valve and its spindle and receiver may float upon the mercury and form an equilibrium valve. The lower end of the central spindle projects beyond the case of the apparatus, so that when the engine exceeds a given speed, the action of the governor will force the spindle down and cause it to press against a lever and open a valve to allow the steam to escape. The diminishing valve is similar in principle, but only one receiver and tank is required, and the valve remains open whilst the steam continues at a given pressure, but is partially or quite closed when such pressure is exceeded. The safety valve is also constructed so as to balance the weight of the valve, and is supported or floated upon mercury. Should this valve be fixed in its seating, the steam will force the mercury out of the tank and effect its escape. *Patent abandoned.*

2475. D. MCCLURE. *An improvement in the machinery used for the drying of yarn, thread, cloth, or other wet fabrics.* Dated Nov. 5, 1858.

The inventor places bars of wood, &c., longitudinally over the heated cylinders, sufficiently near to each other to prevent the yarn, &c., when extended from bar to bar from touching the cylinder. *Patent abandoned.*

2476. C. MILLS. *Improvements in the action of pianofortes.* Dated Nov. 5, 1858.

Here the hopper is constructed as follows:—The fly is hinged at its lower end to a block fixed to a key, and there is fixed to the lower end of the fly a projection which descends below the upper surface of the block. The fly is constantly pressed back by a spring, and is stopped by the projection at the lower end thereof coming against a button or surface covered with felt, &c., carried by the block, and this button is adjusted by a screw passed through the block. The fly is therefore stopped below its hinge, by which the action is improved. *Patent abandoned.*

2477. L. S. KORF and F. C. PHILIPTSON. *Improvements in machinery for boring holes in rocks and minerals, for blasting and other similar purposes.* Dated Nov. 5, 1858.

Here a beam is placed in an inclined position, and upon this beam a block is mounted capable of sliding from end to end of the beam. Attached to this block is a cylinder to which steam or compressed air is admitted, and which gives motion to a piston in the cylinder. At each motion of the piston its rod strikes an instrument that is placed below it, and which carries a cutting tool, and the end of the tool is thus caused to penetrate the rock, &c. Between each stroke the tool-holder is lifted by springs, and is turned partly round by a ratchet apparatus actuated by the piston. *Patent completed.*

2478. S. DAVEY. *Improvements in blasting powder.* Dated November 5, 1858.

This consists, 1, in the use of flour, bran, starch, or other glutinous matter to replace a part of the charcoal now employed in the manufacture of powder. 2. In a new mode of graining the same. *Patent completed.*

2479. R. E. PINHEY, and J. WOOD. *Improvements in apparatus for ascertaining the variation of ship's compasses for local errors.* Dated Nov. 5, 1858.

Here the bowl containing the compass card and needle is arranged to fit into a ring of wood-mounted gimbles. This ring has jointed to it an instrument on the principle of a sun dial. This instrument is of the form of a cross, and the joint connecting it with the ring is at its lower end. A time scale is graduated on the two sides of the stem of the cross, and also on the upper side of the two arms, and the shadow is cast by one or other of the extremities of the two arms, or by the upper end of the stem, according to the time of day at which the observation is made. This instrument is set by elevating the stem of the cross to an angle corresponding with the complement of the latitude of the place by a scale marked on the joint connecting the stem of the cross with the ring, and by then turning the ringround until the shadow falls on to the scale, so as to mark the local time of the place (as indicated by a watch); when this is done the stem of the cross points along the meridian of the place, and a line formed on the ring in the same direction (called the meridian line) then corresponds in direction with this meridian, and the angle between it and the line forming the north and south points of the compass is the variation and local error of the compass. *Patent completed.*

2480. J. DE SAXE. *An improved folding joint for parasols.* Dated November 5, 1858.

By means of this invention the handle may be straightened or folded, and also locked or unlocked, by using one hand only. Two open metal cylinders are hinged together, the knuckle allowing them to fold over parallel to each other. One of the cylinders has a strip of metal fixed across the jointed end within it, and flush with the joint, and such strip (which the inventor calls the "catch") forms a projection which fits into the cut in the bolt or latch. The other cylinder contains a solid metal bolt, which fits it easy, and when the projecting pin is pressed to the right or to the left about a third of one revolution of the bolt it turns freely. The top of the bolt is bevilled off so as to form the latch, and to permit it to pass freely into the other cylinder. The bolt or latch has a slot cut in it on a level with the joint of the cylinder containing the bolt, and such slot is cut wide enough to admit and grip or embrace the catch in the other cylinder. A slot about one-third in length of the circumference of the cylinder is cut across the cylinder which contains the bolt, to admit the pin to pass freely through it, and into the bolt or latch into which it is fastened. The pin projects a little beyond the circumference of the cylinder, and may have either a plain head or knob, or any ornamental finish. By pressing the projecting pin to the right or to the bolt or latch turns it on its axis, and its slot slides over the catch, which it thus either locks or unlocks. *Patent abandoned.*

2481. H. N. PENRICE. *Improvements in machinery for tunnelling and driving galleries through rock and other strata.* Dated November 5, 1858.

This machinery is adapted for cutting a cylindrical gallery or tunnel, and it is furnished with a cutter holder or head which carries a number of steel points or chisels on radial arms, and is attached to the piston or plunger of a steam or other engine. There are several modifications included. *Patent completed.*

2482. A. FRYER. *An improved method of supplying the tenders of locomotive engines, and of supplying boilers with water.* Dated November 6, 1858.

This consists in the use of the steam generated in the boiler to be supplied, or the tender of which is to be supplied, or in a separate boiler, to act through suitable pipes or passages upon a float, or upon a piston placed in a tank or cylinder, which, by preference, is fitted under ground, so as to depress the float, and drive water previously contained in the tank up a tube, and through a conducting pipe into the tender or tank, in the case of locomotive engines, or into the boiler or reserveir for other engines. *Patent completed.*

2483. B. W. JONAS and R. JONES. *An improved ship's block.* Dated November 6, 1858.

This consists of an outer sheave or block furnished with a channel, in which two or more pulley wheels are so arranged as to admit of the rope or cable, impinging upon the peripheries, so as to increase or diminish the space between the same, through the medium of a concentric slot-bearing in which one of the less wheels revolves, the large or fixed wheel moving from a common centre as heretofore. *Patent abandoned.*

2484. W. GREEN. *An improved harness trace coupling.* (A communication.) Dated November 6, 1858.

Here a tubular socket or case is fitted on to each end of the whiffle tree or bar to which the traces are secured. This socket or case is closed at its outer end, with the exception of an oblong slot which is made through it, and which receives a correspondingly-shaped button carried on a plate fastened permanently to the end of the trace. This button projects sufficiently far from the inner side of the plate to enable such projecting portion to be introduced through the slot in the end of the tubular socket or case on the whiffle tree. The button having been introduced is turned round so as to effectually lock it inside the case. Small safety grooves are made crosswise or at right angles to the oblong opening in the inner side of the bottom of the case, in which slots the button is retained by the pressure of a helical spring inside the case acting upon an india-rubber plug, which bears upon the inner end of the button, and holds it in its place in the safety grooves, and obviates all chance of the button becoming accidentally turned and disengaged from its socket. *Patent abandoned.*

2485. J. CLIFF. *Improvements in the construction of kilns for burning stoneware, red-clay ware, porcelain, or all other kinds of earthenware.* Dated Nov. 6, 1858.

Within the lining proper of the kiln is built a second lining at a short distance from the former, which lining reaches up to a level with the commencement of the dome, leaving a circular opening at this height entirely round the inner lining. The bottom, which is hollow and communicates with the fire, has holes left in it at proper distances, and over each of these orifices is erected a column of hollow pillars of various lengths (to suit various sized articles), having collars of greater diameter (also with holes) placed upon and between each. These columns rise to the same height as the inner lining. Upon the ledges of the collars (thus left protruding) rest quarries of various shapes, according to the arrangement of the pillars, which quarries thus form so many floors or cupboards for setting the ware in. The top tier is permanently left entire (the hollow pillars finishing above its surface) and are also jointed, thus leaving the body of the kiln free from draughts through it. *Patent completed.*

2486. B. D. WEBSTER and J. HORSFALL. *An improvement in the manufacture of steel wire.* Dated November 6, 1858.

After the steel wire has been hardened in the usual manner, the patentees plunge it into a bath of fused metals. Every one hundred parts by weight of the said bath consists of forty parts by weight of lead, twelve parts by weight of zinc, twenty-six parts by weight of antimony, twenty-one parts by weight of tin, and one part by weight of bismuth. They allow the hardened steel to remain immersed in the bath until it has assumed the temperature of the bath. When it has been immersed sufficiently long it is withdrawn and immediately sprinkled with cold water. *Patent completed.*

2487. W. ZIERVOGEL. *Improvements in apparatus for distilling products from bituminous coal, schist, peat, and other like substances.* Dated November 6, 1858.

Here a series of upright retorts are used which are supplied at their upper ends with the coal, &c., and which discharge the coke, &c., at their lower ends. These retorts are set in an enclosed chamber heated by a suitable furnace. The products of combustion circulate around the lower parts of the retorts, thence into the upper part of the chamber, and away into the chimney. Above the chamber in which the retorts are set is another chamber into which the coal, &c., is fed by aid of feeders, which are closed and opened so as to prevent the escape of the distilled products or vapours. It is preferred that the lower part of each retort should be made of, or protected by, fireclay; the upper part of cast iron. On the inside of each retort is a tubular screw which is caused to rotate slowly therein. These tubular screws are perforated to allow the evolved products to pass into the interior, from whence they are conducted by branch pipes to a main pipe, thence by an exhausting apparatus to a condensor. There are also branch pipes leading from the upper closed chamber to the same main pipe. *Patent completed.*

2488. M. MATLEY, H. MILLER, and T. HALL. *Improvements in the construction and arrangement of steam boilers and furnaces for the purpose of consuming smoke, economizing fuel, and heating the feed water, and also improvements in certain valves connected with steam boilers.* Dated Nov. 6, 1858.

This relates, 1, to boilers and furnaces, and consists in connecting the flues in the boiler together at the end opposite the fires by a connecting flue, so that the smoke of the "green" fire may travel the length of both flues, and then pass over the bright fire. The furnaces are to be fired up alternately, and the draught reversed by dampers opened and closed by rods and levers actuated by the opening and closing of the fire doors. It relates, 2, to heating the feed-water, which is effected by pipes between the end of the boiler and the door frame; the water passes through these pipes, which become heated, and thus impart heat to the water before it passes to the boiler. It relates, 3, to the diminishing valve, and consists of a receiver closed at the top, which is furnished with orifices through which the steam escapes, and is supplied to the box in which the whole is enclosed. These orifices are covered by a sliding cylindrical cover (also closed at the top) fitting over the receiver, and connected at the top to a weighted lever. When the steam in the box and pipes connected thereto is below the pressure required (which pressure is regulated by the lever and weight) the weight is enabled to lift the cover, and thereby allows the steam from the boiler to escape through the orifice and supply the chamber, until the pressure required in the chamber and pipes is obtained, when the steam pressing upon the top of the cap will lift the weight and close the steam orifices until the pressure again becomes too low. It relates, 4, to the syphon valve, and consists of a vessel into which the water of condensation falls, and which is furnished with a valve at its lowest point. The apparatus is so constructed that when a sufficient quantity of water has accumulated to overcome an adjustable lever and weight, the vessel will sink, and thereby cause the opening of the valve, and discharge the water to any amount which may be regulated by the lever and weight. *Patent abandoned.*

2489. J. JACKSON, A. FISHER, and J. J. HARNEY. *Improvements in the manufacture of strips or bands of steel, and in the machinery or apparatus to be employed therein.* Dated Nov. 6, 1858.

This consists, 1, in rolling the steel to the required thinness when in a heated state. 2, in dividing steel into strips by a machine consisting of a slotted bed and a moveable jaw provided with projecting punches. The moveable jaw works in a slide, or in vertical grooves to ensure its accuracy in working, and the punches fit into corresponding slots made in the stationary bed. 3, in hardening and tempering steel by the use of furnaces constructed and heated so as to prevent the steel strips from being overheated. The invention is not fully described apart from the drawings. *Patent completed.*

2490. J. PLATT. *Improvements in machinery or apparatus for preparing, spinning, and doubling cotton and other fibrous materials.* Dated November 6, 1858.

This relates to the mule or similar machine, and consists in a method of putting up the carriage, or putting up the spindles, when the arrangement renders the carriage sta-

Digitized by Google

tionary. The invention is not described apart from the drawings. *Patent completed.*

2491. J. RICHMOND, J. QUICK, Jun., and A. FRASER. *Construction of a meter for measuring water, spirits, or any other fluids.* Dated November 8, 1858.

The patentees claim the application of a plunger or plungers or ram or rams, working in a cylinder or cylinders for the purpose of measuring water, spirits, &c.; also the application of a hollow disc as described for the purpose of passing the same alternately to either end of the cylinder or cylinders or for any other hydraulic purposes, but more especially in connection with water meters of any description. *Patent completed.*

2492. M. OSBORNE. *A new or improved method of ornamenting fenders, stoves, grates, tables, chairs, and couches made of cast-iron.* Dated November 8, 1858.

This consists in ornamenting the said articles when made of cast-iron by ornaments made of glass or china or other vitreous or semi-vitreous material attached to the articles by nuts and screws, cement, fused metal, or otherwise. *Patent abandoned.*

2493. E. ALCAN. *An improved method of treating or preparing materials to be manufactured into paper, applicable to lie-washings in general.* (A communication.) Dated November 8, 1858.

This consists, 1, in the use of a vacuum in the process of opening out the vegetable materials employed in the manufacture of paper, by placing the materials in a vessel in which a vacuum is formed, and connecting the said vessel with another vessel containing the eye or opening-out liquid, which liquid is exposed to the pressure of the atmosphere or of steam. 2. In the use of the same method n the eye washing of yarn and of woven fabrics in their manufacture, and in the washing of linen for domestic use. *Patent completed.*

2494. A. H. DENDY. *Improvements in the construction of breakwaters or wave screens, applicable also in constructing bridges, roadways, piers, jetties, landing stages, and other structures.* Dated November 8, 1858.

This consists in constructing breakwaters of a series of open tubes of a length considerably exceeding their diameter, or the height and breadth of their waterway, disposed in layers, and laid horizontally, and placed in such a position that they shall present a very inconsiderable facial re-istance to the direct action of the waves, as compared with the mass of the structure, and at the same time shall counteract to any desired extent as well the undulatory or oscillatory motion of the waves, as also their breaking or peruussive force, by causing them to pass through such tubes. *Patent completed.*

2495. J. WARDILL. *Improvements in purchases for the raising and lowering of weights by means of chains, especially applicable to ships' capstans and windlasses.* Dated November 8, 1858.

This invention was described and illustrated at page 316, No. 20, of the MECHANICS' MAGAZINE (New Series). *Patent completed.*

2496. T. MAC SWENEY. *Improvements in steering apparatus.* Dated November 8, 1858.

This consists in transmitting motion to the rudders of ships through cones, or conical friction rollers made to act upon and drive a disc or discs, or ring or rings, the surfaces of which are bevelled, or made conical at those parts where the rollers are to travel, and which are connected to the rudder head, the conical rollers being themselves set in motion by a shaft or spindle, on which the steering wheel is keyed, or otherwise fixed. *Patent completed.*

2497. W. HALE. *Improvements in rockets.* Dated November 8, 1858.

This consists in dispensing with the cast-iron plug at the after part, and instead of placing the tangential apertures at one end, arranging them in a plane as near as possible to the centre of gravity of the rocket, between the bored part of the composition and that part towards the head which is left solid, this being in the position of about the centre of gravity of the rocket; and, to give greater stability to the case, the inventor rivets in a cast iron piece, in which the tangential apertures are formed, whereby the burning of the solid composition supplies the tangential apertures for giving rotating motion about the rocket's axis on the side of the cast-iron piece, while on the other side the bored part of the composition is devoted only to giving the onward motion. By this arrangement, the rotation will be effected perfectly without any irregularity, and at the same time greater strength will be given to the case of the rocket. *Patent completed.*

2498. W. SMITH. *Improvements in apparatus for supporting the hauling-ropes when hauling ploughs and other agricultural implements by steam power.* Dated November 8, 1858.

The patentee employs pulleys placed at intervals, and these pulleys he mounts on frames so constructed as to be capable of being put together on the ground and of being taken to pieces. Each frame consists of two short planks or base-plates, having sockets formed in them to receive moveable standards, through the upper ends of which standards (having a head at one end and a screw-nut at the other) passes so as to connect the standards; and, between the two a pulley is mounted on the bolt, which serves as an axis for the pulleys, and is sufficiently long to allow it to traverse a distance so as to adjust its position to that of the rope. *Patent completed.*

2499. T. B. MARSHALL. *Improvements in drums.* Dated November 8, 1858.

This consists in combining with musical drums an apparatus by which they may be tuned at a single operation. In place of adopting the common method of drawing the cords tight, the inventor does this by interposing at one end of the drum between the hoop on which the skin is stretched, and the hoop to which the cords are attached another hoop, having inclines formed on its edge, which rest on similar inclines on the edge of the hoop above. By turning this additional hoop partly round, the hoop above it to which the cords are attached is forced further from the corresponding hoop at the other end of the drum, thus increasing the tension of the cords, and forcing the two skin towards each other. To turn the additional hoop rack teeth are formed on it, and a pinion which receives motion by hand takes into the se teeth. There are modifications included. *Patent abandoned.*

2500. W. C. CAMBRIDGE. *An improved manufacture of tubular iron applicable to the construction of whippletrees and to other uses.* Dated November 8, 1858.

This relates to an iron bar or rod having the property of the tube and the solid bar combined, whereby great strength with lightness is obtained. The inventor forms a tube of any given diameter, and causes to project radically therefrom a rib or flange for the whole or any portion of the length of the tube. This flange may be pierced with bolt holes to permit of hooks, &c., being secured thereto when the tubular bar is used as a whippletree. *Patent abandoned.*

2501. J. F. AMBLET and A. POLART. *Improvements in the manufacture of elastic fabrics.* Dated Nov. 8, 1858.

This relates to elastic fabrics for boots, shoes, gaiters, corsets, &c. The fabric is produced by introducing during the process of weaving threads of caoutchoue in the direction of the warp, the batten and reed being so formed as to receive these elastic threads, which are carried by a set of bobbins, arranged either above or below the fibrous warp threads, and are woven in therewith by the shoots of weft threads. *Patent abandoned.*

2502. E. E. ALLEN. *Inproved machinery or apparatuses for working the propellers of vessels.* Dated Nov. 9, 1858.

This consists in particular modes of arranging horizontal double cylinders for working the screw propellers of vessels. We cannot give space for the details of the invention, which are voluminous. *Patent completed.*

2503. J. S. DAWES. *A new or improved machine to be used for cultivating land, and which may be made applicable as a hoe, a skim, a turf or peat cutter; and a new or improved method of actuating the said machine and other machines used for like operations.* Dated Nov. 9, 1858.

This consists of a series of teeth, tines, forks, prongs, cutting blades, or diggers, supported upon frames, the said frames being carried by cranked axles, by the motion of which as the machine is drawn over the land, the said teeth, &c., are made to enter and rise again from the land in a nearly cycloidal motion. The machine is to be actuated by condensed air. *Patent completed.*

2504. J. F. DICKSON. *Improvements in the construction of railway chairs and other details connected with the permanent way of railways,* Dated November 9, 1858.

This consists, 1, of a modification of the chair at present in use, by the extension of that part of the chair upon which the rail rests, and also in constructing such chairs so as to give a bearing of wood to the bottom of the rail. 2, in an adaptation of wrought iron in the formation of railway chairs, whether such chairs form part of wrought iron sleepers, or are used as ordinary chairs upon wood or other bearers. 3, in causing the bottom of the rail to bear upon one of the wrought iron fishes resting upon the chair on either side of the joint. 4, in supporting the rail between blocks of wood or metal, the lower surface of such rail not resting upon the chair or sleeper. 5, in forming railway keys or wedges of metal so as to receive a block or packing of wood. *Patent completed.*

2505. J. L. JULLION. *Improvements in the manufacture of paper.* Dated November 9, 1858.

This consists in a method of filling up with a substance of light specific gravity the interstices of the fibres composing paper, so as to consolidate and harden the same. To effect this the patentee makes use of compounds of the metals aluminium, calcium, magnesium, and silicum, either in the metallic or oxydized state, and combines with these bases certain acids to produce a substance suitable to his purpose. These acids are commonly known as sulphuric, fluoric, fluosilicic, and silicic; but he employs only such combinations of these bodies as are nearly insoluble in water. *Patent completed.*

2506. M. HENRY. *Improvements in, and in the manufacture of locks and fastenings, and keys for the same.* (A communication.) Dated November 9, 1858.

Here the locks or fastenings are so constructed that their volume may be greatly reduced by causing the key to act on an intermediate piece moving in the curved recess of a piece or plate carrying the bolt, so as to bring this piece forward or backward to open or close the lock or fastening. *Patent abandoned.*

2507. A. HENDERSON. *Improvements in vessels, and in applying rudders thereto.* Dated November 9, 1858.

This consists in constructing a chamber at the bow and stern of the vessel, so that a rudder may be raised into it. The rudders are mounted on a spindle, which moves in suitable bearings, and the spindle has formed on it a male screw, on which there is applied a nut, which rests upon one of the bearings of the spindle, and by turning this nut the spindle may be raised or lowered, and the position of the rudder adjusted. *Patent completed.*

2508. J. FELIX. *Improvements in castors for furniture, and other similar purposes.* Dated November 9, 1858.

To the leg of the piece of furniture an inverted cup is fixed, and receives a ball, or globe of wood, &c., which projects below the edge of the cup, and rests directly on the floor. The ball or globe does not rest on the bottom of the cup, but upon a number of smaller balls so arranged as to be free to move in a horizontal direction. At the bottom of the cup and within it, there is fixed a short stem, from which a disc is suspended at such a distance below the bottom of the cup as just to allow space for the smaller balls to pass between the two. The under side of the disc is hollowed to correspond with the surface of the ball or globe, so that all the smaller balls between the disc and the globe may bear both on the one and the other. All round the edge of the disc is a passage of sufficient size to allow the balls between the disc and the globe to pass from time to time to the space above the disc, and to be replaced by others descending from this space. *Patent completed.*

2509. C. A. BUTLELIN. *Improvements in the apparatus for ginning and cleaning cotton.* (A communication.) Dated Nov. 9, 1858.

This consists in the substitution of a cylinder covered with teeth similar to those used in cylinder cards in lieu of the ordinary saw-toothed gin or cylinder, and in using a stripper running in combination with it by internal gear and pinion. The cotton in the ginning and cleaning operation is also submitted to the action of a brush blower. *Patent abandoned.*

2510. W. CLARK. *Improvements in signals for railways and in apparatus for actuating the same.* (A communication.) Dated November 9, 1858.

This consists of 3 parts:—1. A new arrangement of signal post. 2. An apparatus serving to change the signals of open line when a train passes in front of the signal post. 3. An apparatus for re-establishing the signal of open line after the train has passed a certain limit. These several parts are not described apart from the drawings. *Patent completed.*

2511. S. S. MARLINO and J. APPERLY. *Improvements in the construction of fulling machines.* Dated Nov. 9, 1858.

The object here is to reduce the friction created between the cloth and the fixed portions of the fulling machine. The inventors apply to all such parts of the machine as are exposed to the rubbing action of the passing cloth a surface of glass, in the form of rings to line the orifices, and in the form of plates where flat surfaces are to be protected. *Patent abandoned.*

2512. A. V NEWTON. *Improvements in the construction of stairs.* (A communication.) Dated Nov. 9, 1858.

This consists in arranging steps or stairs upon an inclined endless belt, or upon endless chains or ropes; or in jointing the steps together so as to form an endless inclined flight of steps, which work over rollers, and act as elevators when motion is transmitted to the rollers. *Patent abandoned.*

2513. A. V. NEWTON. *Improved apparatus for obtaining extracts or decoctions.* (A communication.) Dated November 9, 1858.

This relates to a mode of applying and arranging a steam pipe and syphon, in combination with a boiler and condensor, for condensing the vapours evolved in the boiling of coffee, &c., and returning the condensed vapours to the boiler, thus preserving the aroma, &c., of the substances. *Patent completed.*

2514. A. V. NEWTON. *Certain improvements in electric telegraphs.* (A communication.) Dated Nov. 9, 1858.

Here the conductor is made to form a portion of the battery used to generate the electricity for setting the telegraph in operation, the action being set up by the water surrounding the conductor, or by the moisture contained in the surrounding earth. *Patent abandoned.*

2515. R. A. BROOMAN. *Improvements in electric telegraphing.* (A communication.) Dated Nov. 9, 1858.

The objects here are twofold: 1, the so arranging of the battery force that electric currents can be transmitted to any required distance without limitation by the action of counter currents when the circuit is broken; 2, the causing of the transmitted currents to record a *fac-simile* of the written or printed message. *Patent completed.*

2516. R. M. ORDISH. *Improvements in constructing the permanent ways of railways.* Dated Nov. 9, 1858.

This consists, 1, in holding and supporting rails by metallic sleepers constructed somewhat in the form of hollow oblate spheroids, having their vertical less than their horizontal diameters. 2, in constructing chairs intended for attachment to wooden or other sleepers of such form as to be slightly elastic, and to permit the jaws formed thereon to be sprung asunder, and by their reaction to hold the rail either with or without the intervention of blocks, wedges, or keys. 3, in securing the ends of two adjacent rails where they abut by a metallic spring clip, forming a curve beneath the rail, and having its edges acting upon plates upon each side of the web of the rail. *Patent completed.*

2517. J. NORMAN and R. HANNAH. *Improvements in furnaces.* Dated November 10, 1858.

In a furnace embodying modifications of these improvements, the bridge at the inner or back end of the ordinary grate bars is formed with passages divided by vertically-disposed "quarries" or slabs of fire-brick, which are fronted with cast-iron bars, forming a grate surface by preference inclined up and back from the ordinary grate bars. An air passage or passages admitting air from the ashpit communicates with the passages formed through the bridge, and it is intended that the air entering from below shall mingle in these passages with the gases entering them from above the ordinary fire-bars. The gases on issuing from behind the bridge will mingle to a greater or less extent with the gases passing over the bridge, and will impinge against a second bridge formed with passages which are inclined in plan in various directions to induce a thorough mixing of the gases. This mixing is also further promoted by a third bridge placed immediately behind the second, and formed by preference with its top edge slightly projecting forward, but without passages through it. The details may be variously modified. *Patent abandoned.*

2518. J. CORNER. *Improvements in machinery for making metallic screw rivets, and for uniting with them parts of boots, shoes, portmanteaus, leather hose, buckets, harness, and other leathern articles.* Dated Nov. 10, 1858.

This consists in the use of a bobbin chuck, screw-tools, and shears of a peculiar construction, for carrying, advancing, and cutting the thread, securing the wire into the leathers, and cutting off the rivet when so screwed in. *Patent completed.*

2519. J. BUCHANAN. *Improvements in propelling vessels, ships, and boats.* Dated November 10, 1858.

This consists in propelling ships, boats, &c., by means of a rectangular float board, disposed in the centre or keel line of the vessel, and operated by a long vertical transversely vibrating arm driven by steam or other power. *Patent abandoned.*

2520. W. G. TAYLOR. *Improvements in removing the fur from skins, and preparing said skins for tanning.* Dated November 10, 1858.

The patentee moistens the flesh side of the skin, places it upon a curved top table or block and stretches it, then fastens it to the tenter hooks and removes the fur with scissors or shears. *Patent completed.*

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, JUNE 17, 1859.

CAPTAIN FISHBOURNE ON NAVAL ARCHITECTURE

THOSE of our readers who followed us in the analysis of Captain Fishbourne's scientific pretensions which appeared in No. 4 of the present series of the MECHANICS' MAGAZINE, will not have supposed that the gallant Captain's recent paper has been reproduced in our columns* because we endorse his statements, or think his reasonings sound. Our object has been simply to afford to those persons who are capable of forming a judgment in such matters an opportunity of examining for themselves the grounds on which he condemns the English ships of war, and to remove from ourselves all suspicion of unfairness, in the somewhat severe remarks we are about to make upon his paper. This paper, which, as our readers will have observed, was read at the United Service Institution, contains, among others, the following statements:—"The present practice (of naval "architecture) for war purposes bears the re-"lation to what it ought to be that the service "ordnance does to Armstrong's guns. Not "that ships may be designed that shall sail or "steam fifty times faster than at present; but "they may be made some indefinitely large "quantity more valuable for war purposes—it "may be, in some cases, fifty times more so, "and at less cost." "Had we adhered to the "principles contained in these earlier forms we "should have more efficient ships than we now "possess." Speaking of the French "Gemappes," now in process of conversion into a shell-proof razée, he says, "It is very much to be doubted "that this ship will prove a good sea-going "ship, and yet, owing to her small breadth as "compared with her immersed depth, and the "large amount of ballast she carries, she will "be much more likely to yield a satisfactory "result than any in our service." "I have "stated my opinions decidedly, because I feel "assured that the whole subject of naval ar-"chitecture requires re-consideration, and that "our ships should be designed upon some more "definite and satisfactory principle than they "are."

It must be admitted that these are very serious statements, and that they ought not to be rashly made—indeed, no man has a right to make them at all, until he is prepared to show where the assumed error in principle lies, and to point out the true course.

Perhaps Captain Fishbourne thinks he has done this—for he asserts that our ships are unsteady because they are too broad—that "great "beam is an unmixed evil;" "the wider the "vessel and the less the depth in proportion the more violent will be her rolling;" or, as he said in the letter to Sir John Pakington, "to ob-"tain the steadiest platform the immersed body "must approximate to the volume (*sic*) and "form of a semi-cylinder." We showed in our notice of that letter that the premises of the reasoning by which he arrived at this conclusion were false and absurd. It is true that he now avoids that ground; he seems also to have discarded the remarkable formula for obtaining the amount and velocity of rolling; but as his reputation as an authority in naval architecture, and his apology for talking and writing on the subject hang by this sheet-anchor, he clings to it in the seeming consciousness that it is his last hope. In our former article we said, "Regardless of stability, *i.e.*, the power of resisting an inclining force, the writer directs his attention to the amount of the angle through which the ship rolls in a given time in a rough sea as the measure of her steadiness;" but in this paper we find him directing all his attention to the effect of form upon this "statical stability." His mode of treatment in this case is as original and his arguments as baseless as in the other.

We have not patience to follow him step by step to point out where he is wrong. We can really see nothing worth the trouble of stating which is right. In his attempt to show on page 333, "the influence of depth" on the stability of ships, he says what simply amounts to this, that if the volume of the immersed part of a ship were increased in the region of the keel while the ship is inclined, "the effect would be to float "the keel up, and diminish the stability." The monstrous absurdity of such a statement will be evident to every one if it be supposed, as it may fairly be, that the weight of the part added and of its contents made its specific gravity equal to that of a mass of iron or lead. Further on he says, "The common idea that when a vessel inclines she revolves round her centre of gravity cannot possibly hold, even approximately, in vessels of such a form." We need hardly tell any of our mechanical readers that every ship which revolves at all has a rotary motion about her centre of gravity as truly as she has about any other point from which that motion may be regarded—not certainly as *a fixed point*, that is no part of the "common idea"—it was left to Captain Fishbourne to discover that there is "some (one) "point on the other side of the centre of "gravity" about which the ship will rotate when the inclining force is applied on the side. After pointing out "the mistake" with regard to stability which has injuriously affected nearly all our modern ships, he boldly proceeds to describe the correct form, of which he also gives us a section. "In vessels of this form, "the points of pressure are all equally distant "from the centre," *i.e., the transverse sections below, and for some little distance above the water are circles swept from the centre of gravity as a centre.* There is not the least doubt that Captain Fishbourne has really discovered how to prevent *uneasy* rolling; a ship so constructed would not distress her crew by the obstinate resistance with which ordinary ships indicate their unwillingness to go over, and which we have been accustomed to call their stability—she would, in fact, have as little objection to float with her keel upwards as in any other position, and would be in that respect greatly to be preferred in Captain Fishbourne's opinion to those stiff and rebellious ships of war which will kick and plunge in the most violent manner rather than submit to be turned upside down. Captain Fishbourne's model ship would see no reason for preferring one position to another; and we defy him to show her, or us, why she should. The stability of floating bodies depends on the vertical motion of one or both of two points, viz., of the centres of gravity of the body, and of the water displaced by the body; the former of these is commonly known among naval architects as the "centre of gravity," and the latter as the "centre of buoyancy." If the form of the body and the position of the centre of gravity are such that this centre does not rise with regard to the surface of the water as the vessel is inclined, then there must be a vertical motion of the centre of buoyancy, or the vessel will turn over. A vessel constructed of the form proposed by Captain Fishbourne would have no vertical motion of the centre of gravity because it is in the load water-line, and the form between wind and water will not tend to raise it. Still, the vessel would resist an inclining force if it were broader than it is deep, so as to cause the centre of buoyancy to descend under the action of the force; but the circular form prohibits this, and the ship would therefore have no stability.

Secondly: A ship may receive her stability from the motion of the centre of gravity during the inclination, the centre of buoyancy remaining always at the same depth below the water's surface. The American cigar vessel is under these circumstances; the form below the water undergoes no change upon an inclination of the vessel, and therefore the centre of buoyancy is always at the same depth; and to obtain the stability the centre of gravity is placed—not as Captain Fishbourne has it, *in* the centre of figure—but some distance below it, so that a rolling motion causes a vertical oscillation of the centre of gravity.

Thirdly: Stability may be obtained by a vertical motion of both these centres, as is the case in all ordinary vessels. In men-of-war the centre of gravity is always near the load water-line, so that there will be no considerable motion of the centre of gravity unless the vessel widens suddenly just above the water-line; and it is therefore usual, as it is certainly best, to depend for the stability upon the vertical motion of the centre of buoyancy alone, which can only be obtained by making that great disproportion between breadth and depth about which Captain Fishbourne complains. It matters not how greatly the recoil of the guns may be reduced; this disproportion must continue so long as we require a distinction between the top and the bottom of a ship. Every naval architect knows that he cannot increase the breadth of his ship without sacrificing speed, and he has to determine by experience what the limit may safely be.

We shall not attempt to disprove Captain Fishbourne's alleged facts with regard to the errors of the Government architects in this matter, but simply give two illustrations of ships of war which have been proved by careful experiment to have reached the limit of safety. Neither of these ships is armed as a first-rate, yet in both the proportionate breadth greatly exceeds that which he appoints, viz., twice the mean depth. They are the Conqueror, length 240 feet, breadth 55 feet 6 inches, mean draft of water 25 feet 6 inches; and the Royal George (an old ship converted for a screw), length 205 feet, breadth 54 feet 6 inches, mean depth or draught of water 25 feet 6 inches. We can offer our personal testimony to the fact that this latter ship is so crank as to have inspired fears for her safety when only lying across a tideway in Sheerness Harbour.

We need hardly say that Captain Fishbourne has altogether misunderstood the nature of the motions which he affects to explain, and about which he says the constructors of all our modern ships have been in error; but in attempting to show how a vertical motion of the centre of gravity may be produced in broad, flat-floored ships, whatever may be their shape at the water-line, and wherever that centre may be situated, he makes some very amusing statements. It appears, according to him, that if a ship is flat-floored, the bilge will not go down when the opposite side is lifted by a wave. "The water becomes," he says, "as though it "were rigid." We have only therefore to make the lateral motions sufficiently rapid, to get such a ship quite out of the water. The starboard side is lifted, and the port bilge refuses to go down and recover the displacement—the port side then rises, and the starboard bilge finds the water to be "rigid." The ship would be,

in fact, in the position of the Sphinx or other Egyptian monster which Stephenson is said to have unearthed for the French *savant*, who had written home for further instructions when he found it impossible to raise the ponderous mass without expensive machinery. Stephenson, observing that it rested upon a firm bottom in a shallow vault, and that it was possible to give it a rocking motion, offered to land it for £10, and to put it down again for another £5. His aid being gratefully though doubtfully accepted, he directed sand to be shovelled into the vault beneath the base of the figure as it was rocked from side to side. The sand being like Captain Fishbourne's water, the sagacity of the English engineer was soon rewarded with success.

We have confined our attention to that part of the paper before us which treats of the forms of ships of war, because the main object of the lecturer has been, as he says in his opening sentence, "to show the necessity for a change "in the present practice of naval architecture, "in order that the country may obtain the full "benefit of Sir William Armstrong's admirable "invention." We think we have shown that however desirable it may be to endeavour to diminish the amount of rolling in ships of war —a fact which we suppose no one ever doubted —it has not been proved that our ships are built on false principles, or that "a change in the "present practice of naval architecture" is necessary. We should be sorry to have to prove that all the recent designs from the Admiralty are faultless. Naval architecture has always been a system of compromises—an attempt to secure as much as possible of directly opposite qualities. Nothing can certainly be of so much consequence in providing for the safety of the ship as to make her stable; but in doing this, as we have seen, we bring checks upon the ship which will not always act with the ease and regularity of a steel spring, or a steam "cushion." Perhaps we may one day know how to do this. Naval architects will certainly welcome with pleasure any real help towards its accomplishment. If Captain Fishbourne wishes to aid them, let him be assured that it is on the open sea, and not in the lecture-room; by careful experiment, intelligently made and honestly reported, and not by false criticism that he will improve the condition of the British Navy.

SCREW PROPELLERS.

IN his recent work on "Naval Warfare with Steam," Sir Howard Douglas, in the clearest and most forcible manner, urged the adoption of what he conceived would be a great improvement in the form of the screw propeller. This improvement consisted in removing the leading corners of the blades, and breaking the leading edge of each blade into its circumference by an easy curve.* The first object sought by Sir Howard in making this change was that of reducing the "shake" or vibration of the screw, and the consequent injury to the stern of the ship. These are produced, he argued, by the sudden and violent reactions of the disturbed water against the blades as they enter and emerge from the space between the two sternposts; the rectilinear edges of the ordinary screws being, in this respect, highly disadvantageous, since the whole of an edge enters and leaves at once the water on each side of the aperture. "But if "the leading edges of a screw-blade were curved, "they would slide obliquely and continuously "through the water, like a screw formed with "an entire feather, so that, at no moment, "would there be any shock or discontinuity of "action." Further advantages which Sir Howard considered the curved edges would possess were, that they would readily throw off any floating materials that might come in contact with them—that they would not be so liable to be broken by their oblique collision with large spars as straight edges are by their direct blow—that their rounded extremities would be less liable to be hitched by ropes than the angular extremities of the common screw—and, finally, that if the curved parts could be furnished with incorrodible sharp knife-edges they would divide, and disentangle the screw from, any rope, spar, or other floating matter with which it might become fouled. "The "author would not," said Sir Howard, "at the "sacrifice of speed, revert to a continuous "feather-screw; but the form here recommended would, to a considerable extent, gain "the proposed ends." Now, in justice to an able and veteran officer—an officer who, by his incomparable writings on naval and military science, has commanded the profound admiration and respect of both services—we revive these passages of his latest work, and couple with them a reference to those remarkable experiments the results of which were recorded in our last week's impression. Those experiments show—if the report which is before us may be trusted—that the improvement recommended by Sir Howard does actually accomplish his first and principal object by reducing the vibration or shake of the screw as he predicted. They also show that it has the further important effect of improving both the speed and the steerage of the ship. The reporter tells us that "the first trial with the Admiralty "screw was with a diameter of 18 feet, her "speed being 11·823 knots. On the second "trial, with the diameter increased to 20 feet, "the speed realised was 11·826 knots, with a "great increase of vibration. On the third trial "the leading corner of each blade was cut off, "and in this form the common screw attained "its greatest speed, giving a result of 12·032 "knots. On the fourth trial both the corners "of each blade were cut off, when, with a "greater number of revolutions, less speed was "made, being 12·012 knots. Its last trial, with "the 'following' corner of each blade cut off, "but the screw restored to its perfect form in "every other respect, gave a result of 11·815 "knots." The reporter also says, "the leading "edge of the screw is the part that mostly af-"fects the steerage of the ship, and also causes "the greater part of the vibration."

We direct attention to these facts solely from the desire to aid in reflecting upon the gallant author of "Naval Warfare with Steam" the credit that is justly his due. This may seem to some a romantic thing to give ourselves any trouble about; but romantic or not it affords us much pleasure. For we confess to feeling a peculiar interest in the reputation of a man like Sir Howard Douglas. Those of us who have to wade through the many volumes which mere pirates and charlatans compile and publish, acquire a reverence, aye, an affection, for works like "Naval Gunnery," "Military Bridges," and others of Sir Howard's, in which care, patience, industry, intelligence, masterly skill, and many other virtues and endowments, are stamped upon every page. There is something almost sacred to us in these fruits of human power and excellence, and still more so in the men by whom such fruits are produced.

In the particular instance of Sir Howard's judgment under notice in this article, we are the more anxious to do him justice, because in the review published by us on the 31st December last, we attached but little importance to it, if we mistake not. Nor do we now place anything like implicit confidence in the avowed results of the experiments with the Doris. Still, as we have only our theoretical opinion to bring against them, we are willing to confer the full benefit of the report upon him to whom it belongs.

* See the illustration on page 14 of the MECHANICS' MAGAZINE, No. 1, New Series, for December 31, 1858.

COINAGE DESIGNS.

A CITY correspondent, who has taken a special interest in our recent articles on the coinage of the realm, has favoured us with a suggestive letter on an important branch of the subject. The copper coinage of a full-sized halfpenny commenced, he says, in the reign of Charles the Second, and has been continued to the present time. At first the reverse was a Britannia, in rather old-fashioned costume, said to have been intended as a portrait of one of the king's favourite ladies. This figure of Britannia was partly taken from a Roman coin of Antoninus, for she was represented sitting on a globe, having a shield at her left side, a spear in her left hand, and an olive branch in her right hand; but she has no helmet upon her head, nor is there any ship near her. In 1771 the copper coinage of George the Third was much the same, and in 1797 and 1799 Britannia still appeared bareheaded, with her shield and olive branch; but she was seated on some rock-work, overlooking the sea, and instead of a spear she had a trident in her left hand. A three-masted ship was also seen on the water in the distance. These coins of 1797 and 1799 were struck at the Soho Mint, at Birmingham, and are fine specimens of engravings. The coins of 1806 followed and were similar on the reverse to those of 1797; but the size of the penny was decreased. The coinage of late years has been very indifferent, and the Britannia most slovenly arranged. Instead of a copy of the beautiful figure on the reverse of the penny piece of 1797, we have still a Britannia sitting on nothing, yet armed with a trident, wearing a helmet, and having her shield at her side; the ship and the water, the distinctive characters of Britannia, are passed away. We have before us, by the favour of our correspondent, a copper halfpenny of George the Third, 1771, when the mint was in the Tower of London. On this Britannia is seated on the globe. We have also the penny of 1806, where she sits on rock as before stated. On comparing it with a modern penny the falling off in the design is very manifest.

The subject is one of great interest, and as an issue of new copper coins is contemplated, we would earnestly press it upon the attention of the authorities. In this age of art-progress, it would be discreditable indeed to put an absurd, or even an imperfect, design upon those coins which the eyes of every man, woman, and child in the kingdom are certain to look upon. The Romans, by seating Britannia on a globe floating on the sea, with a shield by her side, a spear in one hand, and a Roman standard in the other, reminded the people with the utmost plainness that Britain was at once insular, warlike, and *subjugated*; why should we not repeat the tale of our present greatness and independence with equal force and clearness?

A correspondent, "A Mc. G.," writes:—"At page 363 of the present volume of the MECHANICS' MAGAZINE, &c., you describe a method of clearing drains and water-courses of extraneous solid matters by means of a grating of a peculiar construction, and patented by Messrs. Easton and Amos. Can this be any improvement on the simple and efficacious plan suggested by me, and which you were so kind as to insert at page 181 in the last volume of your work? In your leading article, page 374, of this week's number, you state, 'unhappily there is no prospect of deliverance from the curse of this foul stream'—the Thames; the simple plan I have suggested would no doubt mitigate the evil if adopted, and, in fact, almost annihilate it."

MONEY-MAKING AT THE ROYAL MINT.

No. II.

As the visitor to the Mint, after having entered his name in a book kept for the purpose at the central office, passes with his guide through the folding-doors at the back of the office, he finds himself looking into a square, or rather quadrangular space, about 100 feet in length by 80 feet in width. The building on his left is the melting-house, that immediately facing him the great rolling-room, and that on his right the coining press-room. An iron tramway, passing down a stone inclined plane, and then branching to each of these buildings, connects them all with the central office. Down this tramway, in strong omnibus trunks, are passed the assayed ingots of gold or silver, and they are destined for the melting-house station. At the melting-house accordingly they are received, carefully weighed, and then charged into the crucibles in companies of six, together with the requisite amounts of copper alloy. As the ingots are eight inches long, three inches wide, and about one inch in thickness, and are worth about £800 each, it is clear that each crucible when loaded is worth, in round numbers, £4,800. There are seven furnaces for the receipt of potted gold, and 50 crucibles per day are frequently passed through this ordeal by *charcoal* fire, thus giving an aggregate value of £250,000. A short time suffices to reduce the rigid ingots and their companion of the baser sort to a state of fluidity, and by stirring them they become intimately blended. The moulds are in the meantime prepared to receive the precious contents of the crucible, being ranged in a strong frame, supported by wheels, bound together by iron bars, and holding their mouths vertically to catch the rich potion intended for their throats. These moulds are made of cast-iron, have been accurately planed from end to end, and being each put together in "two halves," are easily separated when the metal within them solidifies. The subsidence of the gold in the upper part of the moulds in cooling, and the inconvenience caused by it in the shape of "cracked coins" afterwards, have been spoken of in the MECHANICS' MAGAZINE in time past. These evils are in process of removal by improvements in pouring and in the subsequent treatment of the bars, and it is therefore unnecessary to go over that ground again.

We will suppose, then, that the moulds are ready, the metal fused, the workmen prepared, and all minor appointments made; crucible No. 1 is now—by the aid of a kind of iron pump-handle, suspended from the ceiling and having attached to it a ring of the same material, large enough to clasp the circumference of the crucible under its "lip"—removed from its fiery bed and guided by a workman to the mouth of the first mould. The weight of the crucible and its contents is partially taken off the hands of the pourer by means of a hook dependent from the roof, and he has little power to exert save that sufficient to direct the lip of the crucible to the mouth of the mould, and to pour a portion of the charge into it. Practice enables the pourer to judge with great accuracy as to the rate at which to deliver the molten gold, and his ear tells him when the mould is full. Just as a bottler of golden sherry can determine by ear when the wine reaches the neck of the bottle he is filling, so does the gold caster at the Mint know by the varying sound of the yet richer fluid with which he deals when his mould is full enough. The series of moulds in *one* frame being thus filled, that frame is pushed towards a cold-water cistern, and another frame is wheeled forward with its batch of empty moulds. The operation of filling these is a repetition of that which we have described, and one after another other series of moulds are filled until all the ingots are converted into bars. The moulds are now opened successively, and bar after bar is plunged into cold water, the plunger holding them—as a smith pieces of iron—in a pair of tongs, until they are quite cold.

Placed on an iron-faced bench, the bars are now trimmed on the edges, if haply they require that process, and are ready for the rolling department. The mode of casting bars for half-sovereigns is precisely similar to that of casting sovereign bars, and their respective dimensions are for—

	Length.	Breadth.	Thickness.
Sovereigns	21 in.	1¾ in.	1 in.
Half-sovereigns...	24 in.	1⅛ in.	1 in.

The silver-melting house or *room*—for both it and the gold-melting house are under the same roof—is much larger than that for gold, and its arrangement is different. It has to deal with metals in larger quantities, if of lesser value, and requires, therefore, more mechanical appliances.

It has been said that silver is purchased by the Queen, or for Her Majesty, in the market and it reaches the Mint in ingots. The silver ingot is gigantic in size as compared with the gold. It is 13 inches in length, 5 inches in width, and 4 inches in depth, its weight being 1,000 ounces, its value £250—a costly brick in truth. These are melted, three together, in wrought-iron pots of the finest quality, resting in furnaces of much larger dimensions than those of which we have spoken. There are eight silver-melting furnaces in the Mint, and in times of pressure they are all alight together, and produce from two to three tons weight of bars daily. We have said that the mechanical appliances are more numerous, and the foregoing statement will demonstrate the necessity for them. There are mould-frames and moulds of similar construction to the others; but there are also two pivot cranes whose sweeps embrace the whole range of furnaces, and these are used to deposit and remove the charged melting pots. A very excellent plan is adopted, too, for pouring the silver; supposing, as before, that all is right for casting, that the moulds are oiled, and each of the workmen—like sailors at a gun on board a man-of-war—at his post, a pot is next removed per crane and tongs from its hot seat. This is turned by means of the crane's steering gear until it is brought near to, and a little above, the mouths of the moulds; the pot is then dropped gently into a carriage placed to receive it. The metal has an incorporating stir given it at this stage, and the alloy — usually copper halfpence, or farthings, which have been spoilt in their manufacture—becomes diffused equally throughout the liquid mass. By means of a crank, a quadrant rack, and a pinion, the carriage, with its seated pot, is now under complete control of the caster. He gently turns the handle and the pot is gradually inclined until from its spout the purply-white mixture flows, and the mould beneath tells, as before, of its fulness by the gurgling variations of sound produced from within. The first mould filled to the surface, the caster waits till his assistant has pressed forward by rack and pinion the second mould. Again the pot is inclined till the notes of the gamut—and visitors are enjoined to silence at pouring-time—catch his ear and warn him to refrain from allowing more metal to pass into the mould than it will contain. As in the gold melting, pot after pot, and mould-frame after mould-frame, are advanced to their meeting places, and the transformation of fluids into solid rigid rectangular bars goes on until all the material of the day is used up. The bars are next trimmed—the trimmings being carefully preserved—the pots scraped, the room is swept, every precaution to prevent *waste* is taken—the whole proceeds of the day's work are passed through the scales, and the books are made to record the differences occurring by volatilization and evaporation to the greatest nicety. With this last matter we have, however, at present nothing to do, and it will be sufficient to give the dimensions of the bars produced, and then an account of their successive stages of advancement to the high honour of becoming current coin. The size of the bars are as follows:—

	Length.	Breadth.	Thickness.
Florin	21 in.	2½ in.	1 in.
Shilling	21 in.	1¾ in.	1 in.
Sixpenny	21 in.	1⅛ in.	⅛ in.
Fourpenny ...	21 in.	⅞ in.	¼ in.
Threepenny...	„	„	„

these sizes being, it is presumed, found by practice to be best adapted for the production of the sundry coins named. Crown and half-crown coinages may be said to be completely discontinued; whilst *medal* bars of fine silver are, we are told, cast in florin moulds.

It may be hoped that the reader has been enabled to follow us so far in our account of the progress of a sovereign from the crucible to the coining press, and that, "in his mind's eye," he has seen the melting process performed. The rectangular bars, whose dimensions we have just given, are now once more tested by the assayer, and, if approved, are forwarded to the central office. Here, again, the weighing operation is gone through, and this time in presence of a representative officer from the coining department, who, at the end of the total number of "drafts" from a particular melting, writes his receipt for the bars, and accompanies them down the inclined tramway to the great rolling-room. This noble room, which has an iron roof and is well ventilated and lofty, contains machinery of a very massive kind, and which, indeed, appears to be little the worse for the forty-nine years' wear and tear it has had. A thirty-horse engine at present gives motion to the whole of the apparatus in this apartment; but this power has recently proved inadequate to the duty required to be done by the rolling mills, and Messrs. Hall, of Dartford, are erecting a double cylinder forty-horse power engine to meet the pressure of work. In the old engine the fly-wheel is placed on the second motion shaft, and a great speed is given to it by means of a wheel on the crank-shaft working into a pinion on the fly-wheel shaft. Thus, though the engine makes, according to the old rule of Boulton and Watt, but 22 strokes per minute, the fly makes 70 revolutions in the same time. A thick wall separates the engine from the rolling-mills, but an arched space permits the fly-wheel shaft—of cast-iron, and nine inches square—to project into the rolling-room at a hoist of about two feet below the thick granite pavement, and on the end of this shaft is keyed another pinion. This pinion, with teeth about 12 inches broad and of 2½ inches pitch, gives motion to two wheels, one on either side of it, and these latter communicate motion to two ponderous lines of shafting, running longitudinally in trenches from end to end of the apartment. Upon these subterranean shafts, at proper intervals for the purpose, are placed spur wheels of great strength, and these give direct motion to the mills and other necessary appliances. The trenches are covered with stout iron plates, and these afford support to the heavily-laden trucks, which ever and anon pass over them. There are six pairs of rolls in the Mint rolling-room. The largest of these—and there are two pairs of such—are 14 inches in diameter, and 18 inches long in the barrel or bearing part. The second pair—and of them there are two pairs also—are 12 inches in diameter and 14 inches long. The third size, or adjusting rolls—and of these likewise there are two pairs—are 10 inches in diameter and 12 inches long. With the exception of one pair of rolls, and those for the "breaking down" of slab or tile copper, which is rolled hot, the rolls of the Royal Mint are what are called *chilled* castings, and their surfaces are accordingly as hard as steel, and as polished as the cuirass of a horse guardsman on a review day.

Besides the six pairs of rolls in their heavy standard frames, there are driven from the underground shafts two pairs of circular shears of about 20 inches in diameter, whose cutting edges "dip" to about the extent of an eighth of an inch. These are used for shearing copper only, and they make short and sharp work of the duty. When copper tiles of about 14 inches by 10 inches, and half an inch thick, have been reduced by compression at the mills to a guage something like that of the old "ring pence" of 1797, they are "offered" to these shears, and as their edges run in contrary directions to each other, the sheets of copper are accepted, and very speedily cut into strips wide enough to allow of two rows of pence, four of

Digitized by Google

halfpence, or six of farthings to be punched from each—of course, the strips are further adjusted at the small mills before being perforated. Such, however, is the sole use of the *circular* shears. There is also a pair of boiler-plate shears—as they may be termed—though they deal with metal more costly, if not more valuable than boiler-plate. These are worked by means of an eccentric on the lower shaft, and may be readily engaged or disengaged. They are for cutting gold and silver bars after lamination into shorter lengths. Four annealing furnaces or ovens, with gauges, small portable crane for roll-shifting, &c., scales, annealing tubes, plunging cisterns, and gas-cooking stove, with table and forms, make up the furniture and fitments of the great rolling-room.

We have deemed it better to be thus careful in describing, by aid of letterpress, the interior arrangement of this place, because, an account of the operations performed therein will be the more readily understood.

We will now return to the truck load of golden bars which await our attention and that of the Queen's coiners. Again they have been weighed and are now passed over to the gold and silver breaking-down mill. The engine has been started, and the "couplings" of the various mills purposely made to fit loosely are clanking away with a regularity which makes the sound harmonious almost. The overman regulates the space between the rolls by means of two indexed adjusting screws passing through the mill standards and pressing on the bearing blocks of the upper roll. These fine-pitched and powerful screws are made to move simultaneously by the turning of a crank handle, and they force down the upper roll, or allow it to ascend by the force of counterpoise weights suspended ingeniously in the trench below, at the will of the roller. The index points out the distance between the upper and lower roll, which latter revolves on a fixed and solid bed or bearing. Supposing all to be ready, the bars are now taken singly by the overman and placed between the running rolls. One after another, as quickly as the speed of the mill will allow, they are passed through this compressing machine, and received by a workman stationed at the back of the mill, who places them on an iron wound table beside it. This is the first step in the progress of lamination, and the dimensions of the bars will have now materially changed—they are longer and thinner than when taken from the moulds. The rolls are now made to approach each other more nearly, and again the whole batch are made to undergo the squeezing ordeal. They are yet longer and more thin after it, and they have become considerably heated, too, by compression. The workmen put on their gloves—thicker than those worn at evening parties—and repeat the pinching. Now the bars are so attenuated that their identity is destroyed, and they have become very hard as well as very hot. The shears are next put into requisition, and the waste or ragged upper end of each bar being first removed, they are all cut into about 18 in. lengths. One bar will make five of these lengths, and in companies of five they are now placed in cylindrical copper annealing tubes, made air-tight with pot clay, and submitted on iron carriages to the annealing foreman. Twenty minutes' baking alters the tempers of the cut bars materially, and after a cold water bath they become perfectly pliable and soft. Now they are taken to smaller mills, and little by little they are "pinched"—such, we believe is the word used by the Tower-hill operatives—down to something near the thickness of the sovereign.

The wand of the harlequin is not much thinner than are now these wire-drawn strips, straps, or fillets of gold. Each 18-inch length of bar that *was*, is *now* about four feet long and wide enough to allow of two blank sovereigns being cut without unnecessary waste, side by side and from end to end; but before the perforations commence, something more must be done. The "fillets" are left purposely slightly thicker than the coin requires it to be by the officer in charge; but he has performed his task, and prepared them for the next stage of manipulation. A balancing up, therefore, takes place. The workpeople have not left the apartment during the rolling or annealing of the metal, the messenger and gas-cooking apparatus, together with access to a certain subscription cask of porter, having fortified them for the duty to be done; and they carefully return every particle of gold to the seat of justice—in this instance not blindfold—behind the scale table A pass-ticket is given to the men and boys—of whom, unitedly, there may be a dozen—in the rolling-room, whilst the accepted "fillets," duly ticketed, are passed on to the drag or drawing—or more properly stated, the adjusting-room, and the ends, &c., locked up for re-melting.

The adjusting-room has its subterranean shafting, too, giving motion to sundry machines, which briefly and in order we will attempt to describe. In the first instance, there is the "flatting-mill," and this is simply an adjunct to the drawbench. The flatting-mill consists of two steel rolls, of about four inches diameter and five inches in length, supported on bearings in a light cast-iron frame, and driven by a band passing over pulleys. There is a peculiarity about the upper of the two rolls, which constitutes the feature of the machine. It is not cylindrical, but has three flattened sides to it. The effect of this is, that when the fillets which have been weighed and given out to be operated upon are presented to the mill they get an extra compression at their ends, to the extent of about two inches of their lengths, and are then rejected by the rolls themselves. The workman enters them singly at the moment when the flattened surface in passing round allows of his doing so, and the two cylindrical portions of the rolls administer the necessary squeeze. This thinning of the fillet ends is for a purpose which will be presently explained. It is preparatory to their being drawn or adjusted. The drawbench is a contrivance about the value of which much controversy has existed in times past, and of which there are differences of opinion among scientific men now. It was invented in 1816 by Mr. Barton, and was intended to obviate some of the inequalities which were observed to exist in the metals after they had been acted upon in the rolling-mills. Messrs. Maudslay and Son were the constructors of it, and it is needless to say that the mechanical parts of the drawbench were well fitted. The "beds" of this machine, which is quadrupular in its action, are very solid, and are arranged for holding firmly, and without allowing them to revolve, four pairs of small steel cylinders, each about four inches in length and three-quarters of an inch in diameter. The distance between the surfaces of these beautifully turned, hardened, and polished cylinders is regulated by "set" screws to the greatest nicety, and each pair may be made applicable to fillets for any kind of coin. Supposing, then, that the batch of fillets—whose career we have so far followed, and which are *en route* for their sovereign destiny—supposing that these have arrived at the drawbench, and that one of the four pairs of cylinders are "set" for receiving them, the workman finds no difficulty in passing the thinned end of a fillet between those cylinders. It readily passes, indeed, to the extent of the two inches named.

Well, on the other side of the "beds" is the bench, about 12 feet in length; and longitudinally on its surface traverse four endless pitch chains with brass links. On wheels of small diameter, say three, in and above each of the chains runs a strong steel carriage. This carriage, technically called a "dog," is advanced by hand towards the thinned and projecting end of the fillet, and as the "dog" is provided with sharp steel teeth, it is made to bite the fillet. It is at the same moment attached to the pitch chain, and consequently pulls the fillet by main strength between the cylinders, and thus equalises it in thickness from end to end—or at least ought to do so. In order to test the accuracy of its working, blanks are now cut at intervals from the adjusted fillets by hand-cutting punches, and carefully weighed; if the blanks are found to be uniform in weight from whatever portion of the fillet cut, the work is pronounced "good," and is ready for the next operation.

Variations in the density of the metal dealt with, and other practical difficulties, combine to render the drawbench, perhaps, less satisfactory in its action than theoretically it might be expected to be, and in the new Calcutta Mint—in process of construction at Birmingham—it is intended to dispense with it altogether. Carefully dressed and scientifically arranged rolls will, it is expected, give as good results in the shape of gauged or adjusted "straps" of gold or silver as the Royal Mint drawbench, and we are inclined to believe that such will be the case.

Returning, however, to our task—the adjusted fillets are now cut into handy lengths, and a small pair of vibrating shears, worked by a penduluna and eccentric in the trench below, cut off the thinned ends, which, having played their parts, are doomed to the melting-pot. The dwarf fillets are now ready for the *cutting-room*.

THE NAVIES OF ENGLAND AND FRANCE.

(*Concluded from page* 378.)

ANOTHER feature in the establishment of this fleet is the enormous horse-power employed: 222 ships represent 82,044, an amount nearly equal to that required for the aggregate force of the English navy. Of late years, too, the increase has been very great in the larger classes of vessels, and all the new models have been furnished with engines of great power. This may be carried to excess, as there must be always a proportion betwixt the propelled and the propelling forces; and it has been rumoured that the Napoleon, and the ships of that type, strain and tear very much, and are driven deep into the water by the great propulsion. This, however, is a matter which may be safely left to the judgment of our engineers, as far as our relative efficiency is concerned: given the body to be propelled, and they may be surely trusted to adjust the propelling power. A still more important consideration in the estimate of this fleet is its cost. The proportion betwixt the expenditure and the result will much affect the comparisons of the ability possessed by the two nations in creating navies. If one can achieve the result aimed at by one-half the outlay which the other is necessitated to make, it must have a great advantage in the application of its resources. This is not a question of aggregate production, but of the relative worth of the work and the relative price at which it has been attained. France required not a fleet for dispersion, but for concentration; desired not a navy which might spread and diffuse its influence in remote seas, but one which would give it weight, perhaps supremacy, in the policies of Europe. A nation, however, so purely maritime as England, must be prepared for all exigences and circumstances, must be ready armed with every element of attack and defence which her position, her safety, the protection of her commerce, and the connection with her colonies, may demand. There was an outburst of indignation against the departments when the peculiarities of the Russian war showed the need for gunboats and small vessels, and there were none ready. They have since been raised in great numbers, and two-thirds of them have lain idle; still they are a necessary force; we should and must have them, though their maintenance during the period of their inutility drain the purse heavily. France was fortunate in the time and circumstances of the reconstruction of her navy, and has achieved it with an economy most wonderful for such rapid and efficient results. Much was, of course, due to the system. The same will which designed the steam navy, and proportioned its parts, directed the expenditure also in correspondence; nought was frittered away on alien objects, nought ventured on experiments; the whole available finance was centred on the fulfilment of the one purpose. Thus it comes that France during the seven years has

Digitized by Google

been able to construct, to maintain, to repair, to arm her navy, to keep its dockyards and arsenals effective, to feed, pay, and clothe her seamen, to provide labour, material, and ordnance, to undertake new works and improvements at a cost little less than 39 millions; whilst we have expended for the same purposes upwards of 57 millions.* This gives to one nation an average of 5¼ millions per year—to the other of rather more than 8—a difference in cost certainly not commensurate with the difference of results. The ratio of these statistics may be explained, perhaps, without attributing recklessness, extravagance, or gross mismanagement to one system, or care, supervision, and arrangement to the other; yet still the excess on the side of England would be almost enough to balance the comparative resources of the two countries. In all the items of expenditure there is a difference in favour of France, but chiefly on those involved in construction and armament, amounting to more than a million and a quarter on the average of years. France is spared the small expenses, the repairs, the incidentals, which the dispersion of ships, the fitting and dismantling, the commission of different classes, naturally create, and has, therefore, her whole expenditure not only more limited, but more controlled and more defined by products.

A paterfamilias, whose genius had chosen house-keeping for its field, once revealed to us as a fact of his experience, that the butcher and the baker and the tailor were the least formidable of his difficulties; but that it was the cobbling, the mending, the extras, and the incidentals which made such a hole in the income. It is the same apparently with ship-building: the actual work of construction is a comparatively inconsiderable item, but the mending and the altering, the fitting and the unfitting, are so many maelstroms which suck in the supplies most unconsciously and ruthlessly. That France is exempt and England subject to this drain is the effect of national position. We must, therefore, bear our burden manfully, striving to lighten and alleviate it by method and system, and we shall do both probably with more wisdom now that we are informed of the causes which impose it.

The inquiry, however, into the relative power of the two navies, as it may affect the ultimate supremacy of one or the other, can never find its real solution in the discussion of present strength—it must depend also on the means and capacity of expansion. Let us see how the comparison stands in this respect. France, in her grand effort has almost exhausted the old convertible material, and can, therefore, no longer draw from that quarry, and must rely entirely on construction. She has ten sailing line-of-battle ships remaining, and of these two only are supposed to be capable of conversion. Of 32 frigates, nine or ten are considered worth transformation into transports. Thus, she will very soon have used up the old material, and will then find the strain on the finance heavier and more important. She is known now to have 5 liners building, and 8 screw frigates building; 4 liners, and 1 frigate converting. One of these liners has, however, been included in our list. In addition, there is a new element, the iron-sided ships.† Of these, the committee reports—"Their timbers are of the scantling of a three-decker; they are to have 36 heavy guns, most of them rifled 50-pounders, which will throw an 80 lb. hollow percussion shot; they will be cased with iron: and so convinced do naval men seem to be in France of the irresistible qualities of these ships, that they are of opinion that no more ships of the line will be laid down, and that in ten years that class of vessels will have become obsolete." Our own authorities, however, seem to consider the experiment as of doubtful issue, and apprehend that very serious difficulties will attend its practical adoption. It is also as yet a question as to the sufficiency of defence which iron plates would afford against the extraordinary development of projectiles. No plating will render a ship proof against solid wrought-iron shot; and, though the late trials did not satisfactorily establish the effectiveness of the Armstrong bolt against iron, yet it remains to be seen what may be the issue of experiments with larger and heavier shells. It is our own belief that projectile power will attain such a terrible expansion as to defy defence, and that the idea of protection or impregnability from shot or shell will shortly be an illusion; and we cannot, therefore, think that it is wise to sacrifice the great qualities of speed and manageableness for an uncertain resistance against attack. It would seem that, as with the old armour, the invulnerability of the shielded mass would be more than counterbalanced by its want of mobility. Nor can we accept these batteries as the fittest medium for the application of rifled cannon to the purposes of attack. These wonderful engines, to give effect to their long ranges, will require to be placed in ships which are under perfect command—which are mobile, and possess great speed. These qualities cannot, we think, be given to the iron-plated ships; they will ever be difficult to steer, will not probably move well under steam, and will not be handled with the ease and certainty necessary to insure correctness of aim and great effect for their long range projectiles. This, however, is a problem for practical men, and which experience only can solve. Meantime, France has four of this class building, two of which are nearly complete, and intends to construct two more. We shall doubtless follow in the wake of the experiment if the Armstrong gun do not settle at once the question of defence.

It is contemplated by the French Commission,* "that in 1860 she will have a steam fleet consisting of 40 steam line-of-battle ships, 6 iron-plated frigates, 30 screw frigates, 19 paddle-wheel frigates, and 26 steam transports;" and that this fleet would be capable of "carrying an army of 60,000 men, with all its horses, provisions, and *matériel* for one month." Nor is this the limit of the expansion. It is projected that the augmentation should progress until the steam navy number "150 vessels of war of all classes, in addition to 72 transports," and until the arsenals, the great military ports, be complete in respect of docks, factories, and buildings, "to meet the requirements of the fleet." A sum of nearly nine millions has been deemed adequate for this purpose, and it is purposed that "the expence shall be spread over the period from 1859 to 1871." Here, then, we arrive at a definition of the extent which the navy of France is destined to attain; and it is not such as to daunt or terrify us. It is one that, in the like time, we can easily exceed. The component parts are, however, significant. There will be 45 or 50 liners and 72 steam transports, and these forces would point at something more than the assertion by France of her rightful rank among naval Powers. It would suggest that the army of France is to become a power on the seas. Our own prospective increase would carry us much in advance of our rival. At the same period of 1860, it is expected that England may possess 56 steam liners by the farther conversion of 6 sailing vessels, and 34 frigates, with the possibility of converting 27 more, and razeeing 13 sailing line-of-battle ships. This, however, can only be achieved (and the whole result can scarcely be) by an extraordinary effort. According to the ordinary means and expenditure, the consummation could not be arrived at for many years to come. England has been roused to sudden energy and activity certainly, but the proportion betwixt the established strength and the purposed extension of the French navy, shows also that she, in her start, was compelled to resort to an unusual effort, and employ means and appliances which she did not intend to maintain permanently. When the plans here detailed shall be completed, both nations will have used up their old material; and, as the building of a ship costs about four times as much as its conversion, the future extension of each will be as much a question of finance and resources as of constructive capacity.

The building space and building means at the disposal of France are certainly very great. She has her five great ports, containing an aggregate of 73 building-slips, with three in progress, and 17 docks, with a proposed addition of seven; and these great establishments occupy altogether an area of 865 acres.

Altogether, in achievement and intent, in resource and expansion, we have here a most formidable product, but we see also its limit, its end; and notwithstanding a temporary loss of place, we must feel assured that it is within the scope of the energies and resources of our country far to surpass it, and that we have not lost, nor shall we lose, our supremacy in the art-power of production. * * * *

The policy which this fleet designates is, however, the question of the present time.

Mr. Reed, in summing up his comments, says: "The steady and enormous increase of the French steam navy in large ships appears to point to something very different from a sudden and unsupported descent on our coasts. Two-deck and three-deck steam-ships are by no means the most fitting vessels for effecting such an operation. They are intended, as their name implies, for the line-of-battle, and their production in large numbers by the French Emperor is equivalent to a declaration that, if we have to meet his forces at all, it will not be on our coast or in our harbours alone. He is manifestly preparing to meet us, if need be, or if occasion serve, on the open sea, and to contend there for a mastery of infinitely greater value to him than any mere momentary advantage."

This may be a true deduction from facts. Supremacy on the seas is doubtlessly the ultimate, the grand design of the French navy. Yet, what means the extraordinary expansion of its transport power? The French mercantile marine may afford in this respect insufficient means for the requirements of a great military nation; but the Imperial design is as much beyond as the national supply would be below the fair proportion of the transport to the military power and necessities of the State. The 72 steam-ships which are eventually to be an appendage to the navy of France, the 26 which are now in existence, or in instant preparation, what do they portend? Are they necessities? Are they required for the ordinary needs of the nation? If not, what other intent and purpose may they have? There can be only one—that of giving to France a place and a status for her armies on the ocean—of making the seas and channels the sites of floating camps, which should project her military force in any direction, and give to her might the impulse of a concentration capable of attempting a supremacy by land and sea—capable of annulling the advantages of geographical positions, and giving to a great military population a bridged passage for its ambitions and its aggressions.

History gives little encouragement to any such extended ideas of conquest or supremacy. Yet it may be well to consider what warnings this great line-of-battle and transport fleet may have for us, especially now that the great fallacy of "l'Empire c'est la paix" has denounced itself, and great political combinations are again looming ominously before us. It has one especial, one direct warning—preparation.

This has been already partly heeded. The neglect of former administrations, which had sunk our naval strength far below the standard of national efficiency, or even of national safety, has been redeemed by the energy of the present Government. The whole strength and resources of the nation are being applied to the assertion of our supremacy. All available means are employed—all possible agencies directed to the establishment of our old status as a naval power. For the first time, too, in our naval annals, the country has been informed of the actual strength and relative condition of its navy. First Lords do not usually condescend to such enlightenment. It knows now how weak it was, how much stronger it is, how strong it may become.

We are assured of present equality with France, and are promised that ere the year end, we shall be superior to her in the material of naval war. It has been proposed that during this period nine liners should be converted and six new ships launched. Already four of the converted and two of the new berths are floating on our waters, and will be ready before the end of June as engines of war. This is a goodly instalment, and gives us confidence in our resources and in the men who direct them.

Is it, however, enough to be superior to France? Do not the shadows of coming events, the prospective combinations of the future, warn us to prepare for our old position, our old stand-point —England against the world? It was the position which former wars forced on us: it is one which future ones may render equally inevitable: it is one for which we should be prepared.

In the art-power, the resources for the creation of naval material, we have been, in spite of temporary lapse, and shall be, ever supreme. As builders of ships, and constructors of machinery, we may and shall challenge the world. Our present difficulty lies in a different source—the man-power.

"DELTA'S" PATENT AGRICULTURAL IMPLEMENTS.

IN a former number we illustrated a cheese-press and horse-rake, patented by a gentleman who for some reason prefers to keep his name *incog.*, and to be known as "Delta;" perhaps the success of "Sigma's" implements may have somewhat prompted this conceit, or it may happen that there are reasons why he may not wish it to be known at present that he has patented these implements. We have heard of claims being made to the ideas of employées, and other abuses of power; but we might surmise *ad libitum*—but now to facts.

The illustrations now to be given are the "swing" plough, "wheel" plough, and "double mould board" plough, called also "double tom," and "drill" plough, the last of which we presume to be the more correct, from the purposes for which it is made, viz., forming drills and earthing up the plants sown in drills.

The peculiarities of the Scotch ploughs, besides the almost universal use of the swing plough, is that the framing is all forged: but an explanation of the parts of a plough may render the description more easily understood. A plough generally may be said to consist of the beam, body, head, stilts, turnfurrow, share sole or slade, and sideplate, to which are afterwards added the coulter, and bridle or draught-rod.

In the Scotch plough the beam, body, and left stilt are generally forged together, the body being two pieces of flat iron welded to the beam and flanged at the bottom, to receive another part, the head. The head is pointed at one end, to receive and fit the share, and is a piece of flat iron about 1¾ wide, tapering from 1 to ¼ inch in thickness. The underside of the head is level and flat to receive the slade, and the two bolts attaching this to the frame have countersunk heads. The right stilt is screwed down at the end by one of these, and the turnfurrow, or mould board, or resist, is attached by snugs to the body and stilt.

In the English ploughs the stilt and beam are forged in one, and a cast-iron body is attached to the beam by two, three, four, or five bolts according to size. In some the head is cast on the body, in others there is an adjustable head, so as to elevate or depress the point of the share.

"DELTA'S" PATENT PLOUGHS.

The improvement in this plough, as effected by "Delta," comprises a modification of the two plans. He assumes that the body is the weakest place, there being a transverse strain in the line of draught, a twisting strain communicated by the turnfurrow, and a downward force exerted by the action of the share as a wedge acting against the resistance of the beam and wheels. It has been proved that cast-iron is strong enough for the body; he therefore takes cast-iron as the material from which he makes his beam and body in one piece, whether with the head or not being a matter of taste, as some prefer the adjusting piece. He proposes to make the beam of I section, very light, and to use either toughened or malleable cast-iron, thus uniting strength with cheapness. The cost of the Scotch plough is £4 15s. to £5 10s — the English wheel plough £4 7s. 6d., and the cost of these will be from £3 15s. to £4 5s.

The drill plough is made in the same way, but with adjusting wings, or boards, to set up the earth turned out by the mole nose in front. This is a really good implement, not used for one day and then laid aside for a year, but useful, first in forming the drill, then in earthing up the plants, and may next be used in cleaning between rows, loosening the soil, &c., and lastly, for turning potatoes, &c., out of the drills.

The next implement to the plough is the harrow, and it would be useless to notice the several modifications for different purposes, all possessing the same features differently carried out, to suit their special requirements, analogous, for instance, to the French pough, subsoil plough, &c., &c.

The requirement of the plough is to invert the soil for the purpose of aëration, and the approved form is a furrow slice. Nature having performed

her part, man proceeds to utilize it, and the lumps or slices have to be pulverized. The tools used are large files, or graters, called "harrows," and these have all or nearly all the same characteristics—a number of straight spikes fixed in a rectangular or rhomboidal frame, or in iron bars bent or arranged so as to form a series of rigid lattices.

"DELTA'S" PATENT HARROW

follows more in the track of that invented by Smith of Deanston, who used a number of small quoits, or discs, running free—a plan copied and modified as chain harrows of all sorts, makes, and sizes since. But the idea which seems to have been followed out in this case was to make a harrow that should be perfectly steady and firm in the line of draught yet free to give to the undulations of surface, now working on the crest of the ridge, and now in the furrow; in both cases with perfect ease. Another object to the farmer is, that in this harrow he possesses two or more smaller harrows readily applicable for a single horse—a want hitherto felt.

Fig. 1 shows the two-horse harrow, and Fig. 2 the half, or a one-horse harrow. *A A* are two pieces of wood hinged together over the pin *C*, and forming the frame, from which branch the bulls, *B B*, in which are fixed the tines or teeth. The angle of the bulls with the centre frame is about 30 deg.; and the teeth form tracts every two inches in the one-horse harrow 4ft. 8in. in width—in the two-horse, 9½ft. Any one who has noticed the working of an ordinary harrow, must have observed the rolling pitching motion it has; this is thought to be desirable with some, and to suit them the harrow shown Fig. 3 has been designed.

The advantages of the harrow Figs. 1 and 2 are the readiness with which the teeth may be relieved in case of clogging, and the steadiness of working on uneven land. The wings may be raised singly, not being attached beyond the pair, and as they fold back upon one another, they pack into very small compass, either for exportation or for stowage. Again the angle of the teeth allows them to work quite free. Each harrow is attached to the "tree" or crossbar, and beyond this they are independent of one another.

The harrow shown at Fig. 3, in three parts, consists of the frame or draught pole *A*, and two angular bulls, *B B*, to each, the bulls carrying the tines or teeth, and connected to the frame by the pins *C C*; each bull is free to swing on its pin *C*, and thus in addition to its forward motion has also a free side motion to break any lump with which the teeth may come in contact, but when forced to one side the leverage of the side is increased, and so the harrow is self-righting to adjust itself by the resistance to its proper line. It covers 10 ft. 6 in. in 2-inch tracks at even distances.

These harrows have been severely tried, and are found to be quite clear of the tendency of the ordinary harrows to run in, or fall in front; they are of light draught, very simple, and the cost will not be more than that of the old kind. A new kind of tooth is used for the harrows, Fig. 2, giving less resistance and more evenness of working.

These implements were exhibited by Mr. R. Law, of Shettleston, the maker for the patentee, at the Ayr, Rothesay, Glasgow, and other meetings in Scotland, and met with great admiration and no small success, even allowing for the jealousy and distrust with which novelties are regarded by agriculturalists generally, and especially by our northern friends.

In illustrating these improvements or additions to the farming stock of implements, we consider that we are doing an act of justice to one who has spent much time and anxiety in their improvement, as well as conferring an obligation on our readers in showing them the doings of others, and the means employed to obtain the ends required.

We understand that our English friends will have an opportunity of seeing them at Warwick at the ensuing meeting of the Royal Agricultural Society, where they are entered for competition, and we are informed that "Delta" has entrusted his interest there to one who will do him every justice.

FOWLER'S STEAM PLOUGHING APPARATUS.

THE possibility of economically ploughing, or otherwise cultivating the land by steam power in lieu of that of horses, has been for several years past the belief of many scientific agriculturalists, as well as nearly all mechanical men; but public attention has only very recently been directed to the subject. Indeed, this may be said to have occurred for the first time at the public trials which took place at the Royal Agricultural Society's Show, at Chelmsford, in 1856; for although some few trials had previously been made, the public up to that time were almost wholly ignorant of what had been done. Upon this occasion, however, so great was the interest manifested that it was found impossible to work either the engine of Mr. Boydell or the apparatus of Mr. Fowler, and the trials were consequently adjourned to a more convenient place, viz., Boxted Lodge, near Colchester, where they were carried out on the 13th and 14th of the following month. The prize of £500 had been offered by the Society for a "Steam Cultivator that should in the most efficient manner turn over the soil, and be an economical substitute for the plough or the spade;" and Mr. Smith, of Woolston, and Mr. Fowler, were the two gentlemen who competed for it. It is not our intention to describe in detail the apparatuses then used by those competitors, but it may be well to state that Mr. Smith employed an ordinary seven-horse engine with separate stationary windlass, the wire rope passing over four anchored pulleys, two of these being fixed and two being moveable as the work proceeded. The cost of scarifying or "baulking" the soil by these means was stated to be about 8s. per acre, including every expense, and four acres were so treated in 12 hours. As, however, Mr. Smith's system of cultivation does not turn over the soil, which he considers unnecessary, but which was one of the conditions of the prize, the judges reported that his cultivators did not answer the requirements, although there could be no difficulty in attaching ploughs to his traction ropes instead of the implements he used. Mr. Fowler's cultivating apparatus, on the other hand, being a wooden frame with eight ploughs attached to it, four of them working at once, and balancing those out of use, did completely overturn the soil, and that at a cost of about 7s. per acre, according to a very careful calculation of Mr. Amos, the Society's Engineer. Mr. Fowler's apparatus then consisted of a double cylinder portable engine, driving a capstan by a short endless chain, these being stationed half way down one side of the field, the rope passing round two anchored pulleys and meeting at the implement. The anchored pulleys were very ingeniously constructed, consisting of trucks filled with earth, having sharp cutting discs for wheels, which were easily moved along through the ground, but presented much lateral resistance, which bore the strain of the implement. The cost of ploughing on this plan was so nearly equal to that of horses, being only 2½d.! per acre in excess, that it might have been supposed the judges would have at once recommended the council to award the prize offered by the Society. This, however, was not done, although they reported the ploughing admirably done, and fully equal in regularity and precision to anything which could be done by horses; and, moreover, that the cost of similar horse labour would be, *at least*, the 7s. per acre. The judges did, however, recommend Mr. Fowler's apparatus to the favourable notice of the council, in consideration of the skill he had displayed, the labour and expense he had incurred, and the degree of success he had so honourably achieved.

The next great trial of steam ploughing which the public had an opportunity of witnessing, was that which took place at the Salisbury Show in 1857, upon which occasion there were several additional competitors, including Mr. Collinson Hall and Mr. J. A. Williams. Although the judges had reported that steam ploughing apparatus should be able to convey itself from the farm-yard to the field, this was not attended to either in Mr. Fowler's engines or in some of the others exhibited, Mr. Boydell's engine being the only one that successfully climbed up the hills and turned round the several sharp angles on its way to the trial field. Mr. Collinson Hall's engine accomplished one wonder, but in trying to complete a second one, become disabled, and thus was unfortunately excluded from competing. Little more was done upon this occasion than to prove that steam ploughing had attained a degree of excellence comparable, in point of execution, with the very best horse work, and at a cost as nearly as possible that stated by Mr. Amos at the former trials. But a very important light appeared now, for the first time, to break in upon the view of those who witnessed the trials, namely, that the great advantages in steam ploughing might lie not altogether in cost, but also in *time*; at least *double* the quantity of work being capable of being performed in a day, when that work was pressing. Besides all this, it has now been proved that upon certain classes of clay soils most subject to injury by the tread of horses, the economy of steam culture receives its evidence, not simply in a well-turned furrow-slice, but rather in the quality and quantity of the produce, and that not of one year only but of several; the avoidance of the repeated "poaching" of horses bringing about a permanent and very favourable change in the condition of the soil.

The judges reported after the Salisbury trials that Mr. Fowler's ploughing was "very good," but arrived at the conclusion that considering the wording of the premium, they were not justified in awarding the prize while a *plough* was used. They, however, recommended a medal should be voted to him as "a reward for his strenuous endeavours in a good cause." The apparatus used on this occasion was similar in character to that employed at Chelmsford, but the details were considerably improved, and the anchors made by Ransome and Sims were highly spoken of.

The third great trial of steam ploughing took place in July, last year, at the Chester meeting of the Royal Agricultural Society, and terminated in a report of the judges "that Mr. Fowler was fully entitled to the prize of £500," their award being confirmed on the 4th August, at a meeting of the council of the Society. Five competitors entered at this trial, viz., Messrs. Howard, with Mr. Smith's apparatus, Messrs. Crowley and Sons, Mr. Ricketts, Mr. Boydell, and Mr. Fowler; Messrs. Fowler and Howard being alone, however, the final competitors. Upon this occasion, also Mr. Fowler had considerably simplified his apparatus since the previous meeting at Salisbury, and had greatly diminished the traction power required, and the wear and tear arising from friction. The engine and windlass, as well as the anchors, were also made self-acting. After a very careful inquiry, into the details of which we cannot now enter, the judges came to the unanimous conclusion that Mr. Fowler's machinery turned over the soil in an efficient manner, at a saving, as compared with horse labour, on light land of 2½ to 25 per cent., on heavy land 25 to 30 per cent., and in trenching of 80 to 85 per cent.; while the soil, in all cases, was left in a far more desirable condition, and better adapted for all the purposes of husbandry; and on these grounds they awarded him the prize as has been stated. The trials of Messrs. Howard's machinery induced them to recommend that a large gold medal should be given them "for the practical introduction of Smith's application of steam power to facilitate autumnal cultivation." Thus ended this great contest, after three years trials at the Royal Agricultural Society's Shows; but it would not be doing Mr. Fowler justice if we did not also here record his triumphs in other quarters, viz., at the trial at Stirling, in 1857, where he gained a prize of £200; at Northallerton, in 1858, £50; and also Lord

FIG. 2.

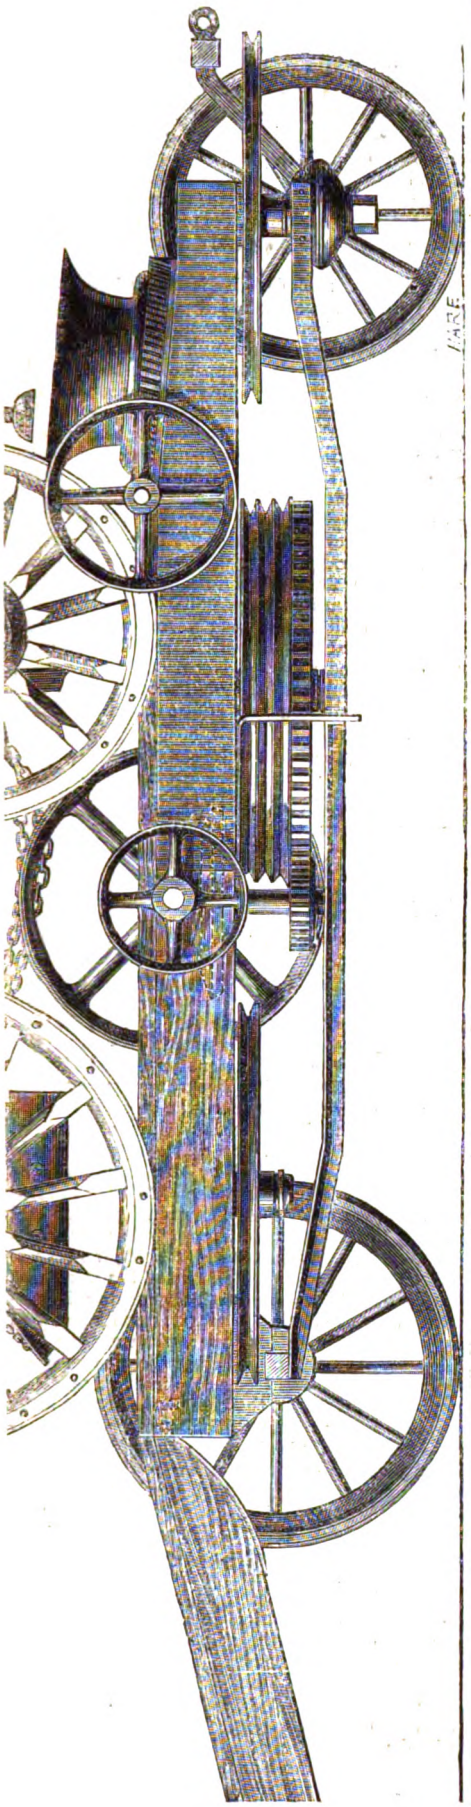

FIG. 3.

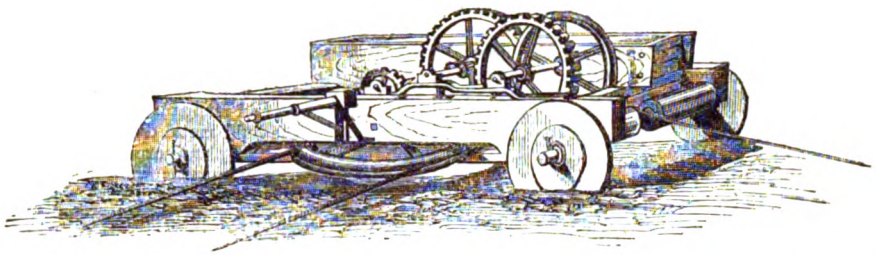
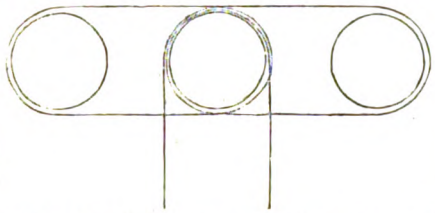


Bolton's prize of £25, at the same place; at Londonderry, in 1858, £50; and again at Stirling in the same year, another £50 prize.

We now come to that portion of our remarks which we had hoped to have reached earlier, viz., the present condition of Mr. Fowler's apparatus, which for simplicity and efficiency we fully believe greatly surpasses anything he has before exhibited. To those who recollect the apparatus shown at Chester, though admirable as a piece of workmanship (as it should have been, considering it was constructed at the works of Mr. Robert Stephenson, at Newcastle), yet presented a very complicated aspect. This fault cannot, however, be found with the machinery Mr. Fowler is now supplying, which from our illustration (Fig. 1) will be seen to be extremely simple, consisting merely of a driving drum attached to the centre of one of Clayton and Shuttleworth's ordinary portable engines, having pulleys at either end for the wire rope to pass round, as indicated in the accompanying diagram, and from which it will



appear that two three-quarter turns are made round the driving drum, which gives ample surface contact to prevent slipping. The drum in front of the smoke box is for working the engine along the headland, this drum being rotated by a shaft and worm shown in front of the drawing. The worm is thrown out of gear altogether when required by raising the drum upwards, so as to wind the rope up. Another important addition is now made of a pitch wheel and chain for assisting the engine into place by steam power, the guiding being left to be done by a horse placed in ordinary shafts. The water tank consists of a circular vessel on wheels, which is attached to the end of the engine, and is drawn along with it. The anchor is now constructed on the same general principle as formerly, only greatly improved, inasmuch as the metal work is entirely of wrought iron, the wheels being placed horizontally instead of vertically. We are prevented by an accident from giving a view of the latest mode of constructing the anchor in this week's number, but have shown one (Fig. 3) of very recent build, and one which well answers the purpose, though the details are inferior to those now adopted. The illustration Fig. 2 shows an adaptation to Mr. Fowler's apparatus of Mr. Eddington's mode of using a common portable engine for steam ploughing by placing such engine upon a truck or carriage upon which it is raised. The details of the arrangement are altogether different from those suggested by Mr. Eddington, the principle of his invention only being used by Mr. Fowler. The drums and pulleys, as well as the drum for advancing the engine, are precisely the same as in the more complete arrangement; and indeed the former plan is only recommended where the engines already possessed by farmers are either too small or too old to make it worth while to alter them in order to adapt them to steam ploughing. As regards the implements drawn by means of Mr. Fowler's apparatus, we need only say that any kind may be used, his own plough appearing the best as far as ploughing is concerned. As this implement was lately described in these pages, we need not further notice it, except to say that such improvements in its details have been made as to render it more completely under control, and less liable than ever to get deranged. Altogether, then, we may now confidently state that whatever may hereafter be done with rotary cultivators moved by engines travelling with them, steam ploughing by the means now adopted by Mr. Fowler is a veritable reality, and may be accomplished in so perfect a manner as to leave little to be desired; certainly nothing whatever which should make agriculturalists hesitate to at once adopt it, feeling assured as we do that the mechanical details if not absolutely perfect, are yet good and highly serviceable, unlikely to get out of order, and indeed we may almost say, as good as those of the engines themselves. If farmers, therefore, before adopting steam ploughing, wait with a view of seeing something more perfect than anything they can now have, we can assure them that they may wait a considerable time, during which they will lose far more in neglecting the advantages which steam ploughing will confer on their lands, than they are likely in all human probability to gain in the way of simpler, or more durable apparatus. Up to a certain point improvements in the details of machinery may be rapid, but when that which requires a wheel and a shaft to turn it, has nothing more than a wheel and shaft to perform the operation, then the utmost simplification has been attained; and waiting for something more will be like making up one's mind not to employ a steam-engine until either the boiler or cylinder is dispensed with.

MR. HENRY BESSEMER
ON THE MANUFACTURE OF MALLEABLE IRON AND STEEL.

THE following is an official abstract of a paper read at the Institution of Civil Engineers, by Henry Bessemer, Esq., May 24, 1859; Joseph Locke, Esq., M.P., President, in the chair:—

Attention was directed, in the early part of the paper, to the ordinary mode of manufacturing iron by the puddling process; in the course of which the iron, after it "came to nature," was gathered into balls, and was then removed as quickly as possible to the squeezer, where much of the fluid scoria, with other mechanically mixed impurities, was driven out, leaving a mass, or billet of iron, composed of thousands of separate fragments of metal, the entire surface of every one of which was, more or less, coated with dry oxide, or fluid silicate of the oxide of iron. The great pressure exerted by the squeezer sufficed to so far remove the fluid coating of the contiguous particles, as to bring their surfaces into actual contact, and consequently to effect a union at such parts. But the whole of the matter thus displaced could not find its way between the interstices of the mass, and therefore it became locked in its numerous cavities, producing points of weakness and separation in the metal. No amount of after working or rolling could wholly displace the portions of cinder, dry oxide of iron

Digitized by Google

and of sand, which thus became mixed up with and were diffused throughout the mass, causing flaws and cracks in the iron, all more or less objectionable.

Now, if these imperfections were the natural and inevitable consequences of the conditions under which malleable iron was at present produced, it followed that defects of a similar character must also of necessity exist in steel produced by the puddling process. The granular condition of the metal and its exposure to heat and oxygen, could not fail, in both cases, to oxydise the entire surfaces of the numerous molecules to be united into one mass; the admixture of scoria and other matters from the furnace was equally certain to result; and also the difficulty of bringing each particle of the metal to the same degree of decarbonisation and refinement existed as in the making of iron, with the additional inconvenience arising from some portions of the metal becoming entirely decarbonised, and being converted into soft malleable iron.

Iron thus presented a most unfavourable contrast with the other malleable metals, all of which were free from sand or scoria; they had no hard and soft parts, and required no welding together of separate molecules, but they were perfectly homogeneous, and free from all mechanical admixture with foreign substances. Gold, silver, copper, zinc, tin, and lead owed this valuable exemption from the defects universally found in puddled iron, simply to the fact that they were purified and refined in a fluid state, and while still fluid were formed into ingots, whereby the cohesion of every particle in the mass was insured. If, then, the refining of other malleable metals, while in a fluid state, and their formation into cast ingots, rendered all such metals more sound and homogeneous than iron, while it did not lessen their extreme ductility, why should iron for ever remain an exception to the general rule? It might be truly answered, that hitherto the excessively high temperature required to fuse and to maintain pure iron in a fluid state, had interposed an insuperable barrier, for the highest heat of the furnaces only sufficed to show that fluidity was a possible condition of that metal.

It need not therefore be a matter of surprise, that when Mr. Bessemer first proposed to convert crude pig iron into malleable iron, while in a fluid state, and to retain the fluidity of the metal for a sufficient time to admit of its being cast into moulds, without the employment of any fuel in the process, his proposition was looked upon by many as a chimera, or as the mere day-dream of an enthusiast; but it was nevertheless fully recognised and supported by many of the scientific men of the day. The same deep conviction of the truth on which the new process was based, and which led Mr. Bessemer to bring it before the British Association in 1856, had since determined him (in spite of the opinions then pronounced against the process) to pursue one undeviating course, until the present time, and to remain silent for years, under the expressed doubts of those who predicted its failure, rather than again bring forward the invention until it had been practically and commercially worked, and there had been produced by it both iron and steel of a quality which could not be surpassed by any iron or steel made by the tedious and expensive processes now in general use. The want of success which attended some of the early experiments was erroneously attributed, by some persons, to the "burning" of the metal, and by others to the absence of cinder, and to the crystalline condition of cast metal. It was almost needless to say, that neither of the causes assigned had anything to do with the failure of the process in those cases where failure had occurred. Chemical investigation soon pointed out the real source of difficulty. It was found, that although the metal could be wholly decarbonised, and the silicum be removed, the quantity of sulphur and of phosphorus was but little affected; and as different samples were carefully analysed, it was ascertained that red shortness was always produced by sulphur, when present to the extent of 1-10th per cent., and that cold shortness resulted from the presence of a like quantity of phosphorus; it therefore became necessary to remove those substances. Steam and pure hydrogen gas were tried, with more or less success, in the removal of sulphur, and various fluxes, composed chiefly of silicates of the oxide of iron and manganese, were brought in contact with the fluid metal during the process, and the quantity of phosphorus was thereby reduced. Thus many months were consumed in laborious and expensive experiments; consecutive steps in advance were made, and many valuable facts were elicited. The successful working of some of the higher qualities of pig-iron caused a total change in the process, to which the efforts of Messrs. Bessemer and Longsdon were directed. It was determined to import some of the best Swedish pig-iron, from which steel of excellent quality was made, and tried for almost all the uses for which steel of the highest class was employed. It was then decided to discontinue, for a time, all further experiments, and to erect steel works at Sheffield, for the express purpose of fully developing and working the new process commercially, and thus to remove the erroneous impressions so generally entertained in reference to the Bessemer process.

In manufacturing tool steel of the highest quality, it was found preferable, for several reasons, to use the best Swedish pig-iron, and, when converted into steel by the Bessemer process, to pour the fluid steel into water, and afterwards to remelt the shotted metal in a crucible, as at present practised in making blister-steel, whereby the small ingots required for this particular article were more perfectly and more readily made.

It was satisfactory to know, that there existed in this country vast and apparently inexhaustible beds of the purest ores, fitted for the process. Of the Hematite alone, 970,000 tons were raised annually, and this quantity might be doubled, or trebled, whenever a demand arose. It was from the Hematite pig-iron, made at the Workington Iron Works, that most of the larger samples of iron and steel exhibited were made. About 1 ton 13 cwt. of ore, costing 10s. per ton, would yield 1 ton of pig metal, with 60 per cent. less lime, and 20 per cent. less fuel, than were generally consumed when working inferior ores; while the furnaces using this ore alone yielded from 220 to 240 tons per week, instead of say 160 to 180 tons per week, when working with common iron stone. The Cleator Moor, the Weardale, and the Forest of Dean Iron Works, also produced an excellent metal for this purpose.

The form of converting vessel which had been found most suitable, somewhat resembled the glass retort used by chemists for distillation. It was mounted on axes, and was lined with "Ganister" or road drift, which lasted during the conversion of thirty or forty charges of steel, and was then quickly and cheaply repaired, or renewed. The vessel was brought into an inclined position, to receive the charge of crude iron, during which time the tuyeres were above the surface of the metal. As soon as the whole charge was run in, the vessel was moved on its axes, so as to bring the tuyeres below the level of the metal, when the process was at once brought into full activity, and twenty small, though powerful, jets of air sprung upwards through the fluid mass; the air, expanding in volume, divided itself into globules, or burst violently upwards, carrying with it a large quantity of the fluid metal, which again fell back into the boiling mass below. The oxygen of the air appeared, in this process, first to produce the combustion of the carbon contained in the iron, and at the same time to oxydise the silicum, producing silicic acid, which, uniting with the oxide of iron, obtained by the combustion of a small quantity of metallic iron, thus produced a fluid silicate of the oxide of iron, or "cinder," which was retained in the vessel and assisted in purifying the metal. The increase of temperature which the metal underwent, and which seemed so disproportionate to the quantity of carbon and iron consumed, was doubtless owing to the favourable circumstances under which combustion took place. There was no intercepting material to absorb the heat generated, and to prevent its being taken up by the metal, for heat was evolved at thousands of points distributed throughout the fluid, and when the metal boiled, the whole mass rose far above its natural level, forming a sort of spongy froth, with an intensely vivid combustion going on in every one of its numberless, ever changing cavities. Thus by the mere action of the blast a temperature was attained, in the largest masses of metal, in ten or twelve minutes, that whole days of exposure in the most powerful furnace would fail to produce.

The amount of decarbonisation of the metal was regulated with great accuracy by a meter, which indicated on a dial the number of cubic feet of air that had passed through the metal; so that steel of any quality or temper could be obtained with the greatest certainty. As soon as the metal had reached the desired point (as indicated by the dial), the workmen moved the vessel, so as to pour out the fluid malleable iron, or steel, into a founder's ladle, which was attached to the arm of a hydraulic crane, so as to be brought readily over the moulds. The ladle was provided with a fire-clay plug at the bottom, the raising of which, by a suitable lever, allowed the fluid metal to descend in a clear vertical stream into the moulds. When the first mould was filled, the plug valve was depressed, and the metal was prevented from flowing until the casting ladle was moved over the next mould, when the raising of the plug allowed this to be filled in a similar manner and so on until all the moulds were filled.

(To be concluded in our next.)

LOWERING SHIPS' BOATS.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—By the tenor of a paragraph which appears in your "Weekly Gossip" for last week, I perceive that you are disposed to share my view of the case—that the opinion of the *Times* correspondent, when he lately drew an invidious comparison between Captain Kynaston's and Mr. Clifford's plans for lowering boats, was rather one-sided, and as it is your object to bring all inventions fairly before the public, I will ask you to insert the following remarks:—

The *Times* correspondent states, "Captain Kynaston's disengaging hooks appear to require *four* men for the operation, the success of which depends on the simultaneous working of the men. By Clifford's method the whole appears to be more safely performed by *one* man, who by slacking off a rope insures the boat being lowered on an even keel." True, Captain Kynaston still retains the only seamanlike way of suspending a boat, that is, by her usual tackles, and these tackles require the attendance of the usual men on board. The process of disengaging is performed by *one* man in the boat, is instantaneous, and completely in his power, whenever the time has arrived; moreover, whether the men on board lower *simultaneously* or not, directly the disengaging line is let go, the boat *must enter the water on an even keel.* Mr. Clifford's plan requires *one* man nominally, it is also true; this of itself might be of advantage, were it not for the great sacrifice entailed by the use of "single pendants," and the safety they compromise.

1st. The boat cannot be disengaged *ad libitum*, or until she has run her whole length of pendants off the roller. For a trial like the Paramatta's, the length of pendant is easily adjusted to the height of the boat's suspension from the water; but at sea not only does the ship's draught of water change with the consumption of coal, but there is such a thing as a *weather* and a *lee* side, which have the same effect. If the boat be lowered from the *weather* side, the chances are she will disengage herself before her time; if from the *lee*, she will necessarily have more pendant to get rid of; this sometimes leads to accidents.

2nd. If the pendants become saturated with

Digitized by Google

moisture, and stiff, they either require the assistance of sundry of the crew to overhaul them, to ensure the boat descending on an even keel, or (as it has frequently happened with our large men-of-war) they break during the process, and throw their crew overboard. If a pendant hangs after the boat has entered the water, she becomes immediately swamped, and her crew probably drowned. I fear an instance of this even might be cited.

3rd. There is great vibration attached to lowering a boat with single ropes, and she is apt in a seaway to be stove against the ship's side; in this latter event Mr. Clifford's boat is helpless, and may be dashed to pieces before the proper tackles can be overhauled down for rehoisting her; on the other hand, Captain Kynaston, by retaining the usual tackles, has completely guarded against a similar evil.

4th. Mr. Clifford's plan of *lowering in the boat* is a great incentive to deserting a ship in time of difficulty—fatal facility indeed!

5th. There is as much danger attending the hoisting a boat in a seaway as in lowering, from the liability of one or other of the tackles to become unhooked—Mr. Clifford makes no provision for this, Captain Kynaston does.

6th. When hoisted at the davits, the single pendants are not sufficient for a boat's security. It is necessary to back them up with the tackles, or else with slip-stoppers. In either case the lowering must be retarded. Our best naval officers moreover agree that, in large ships more especially, Mr. Clifford's pendants, after a short use, are untrustworthy, through the use of the nip-sheaves.

I remain, Gentlemen, your obedient servant,

NAUTICUS.

NAVAL WARFARE.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN, — The improvements now being worked out in the destructive capabilities of war engines will, in all probability, induce not only a change in the construction, form, and size of ships of war, but a change also in the modes of naval warfare.

In the time of Queen Elizabeth, ships were armed with "built-up" cannon of rude fabrication, harmless in comparison with the "built-up" rifled gun of the present period. There were also, in the time of Elizabeth, fire-ships, which did good service in the defeat of the Spanish Armada. The fire-ships of the English were, on that occasion, towed by active row-galleys into contact with the slow and huge Spanish ships, which suffered greatly by that method of destruction. Something analogous to such mode of warfare would be the employment of submarine explosive shells, which do their work some feet under, instead of upon, the surface of the water. By steam-vessels, adapted to the service of these engines, they can with ease, and with destructive effect, be towed into contact with large ships armed with cannon and of inferior speed.

In the Museum at Canterbury is deposited, for public inspection, a submarine explosive shell, to which I would most earnestly direct the attention of engineers and mechanics; who, by taking the matter in hand, may gain such attention as to prevent a useless expenditure of labour and skill upon vessels armed with any kind of gun or projectile at present known, which would in combat at sea prove no match for vessels, of comparatively trifling cost, armed with submarine explosive shells.

I am, Gentlemen, yours obediently,

JN. HARVEY, Captain R. N.

Sandgate, 14th June, 1859.

APPLICATION OF BALLOONS TO WAR PURPOSES.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN, — Seeing in your number of the MECHANICS' MAGAZINE of the 27th of May an article on balloons and their application to war purposes, it has struck me that if a balloon was elevated to a suitable height, and there held by a rope to the earth, that this rope by having a wire in the core of it, and by the aëronaut having a galvanic battery and the other requisite apparatus in the balloon with him, a constant correspondence might be kept up between him and the people below. I throw out this hint for our electricians and aëronauts to improve upon if they see in it anything worth their attention.

I am, Gentlemen, yours truly,

E. FINCH.

Chepstow, June 10, 1859.

Proceedings of Societies.

ROYAL AGRICULTURAL OF ENGLAND.

June 8.—At a weekly Council held on this day, the Right Hon. Lord Berners, Trustee, in the chair. A letter from Mr. R. Wainwright was read relative to a compound that he stated he had discovered to be unusually fertilising. The Council expressed their willingness to receive any further particulars he might wish to communicate. Mr. H. Smythies, of Auckland, New Zealand, addressed an inquiry to the Council as to whether they were in possession of any remedy (poisonous or otherwise) against a small caterpiller, which he stated passes over the face of the country in swarms during hot dry summers and devours all vegetation. A communication from Mr. Greenwood, of Abermant, Brecon, was read relative to an insect that had destroyed his Mangel Wurzel corp. This insect is not seen during the day-time, and the specimens which were placed on the table had been collected very early in the morning. Lord Berners stated that his bailiff had found the Mangel plant on his lordship's estate eaten all over when about an inch high by a similar insect. Professor Simonds stated that his Mangel plants had been attacked by an underground grub. The Council directed the insects to be forwarded to Mr. Curtis, the entomologist, for examination, and also desired it to be stated in the reports of the proceedings of the meeting, that the Society would be obliged by any further information on this subject from the members or others whose Mangel crops had suffered in a similar manner to those above named, and in case any successful remedy had been discovered by an account of its nature and mode of application. Mr. Whitehead transmitted copies of the prospectus of the "Cottage Improvement Society," 18 Adam Street, Strand. Baron de Cetto, of the Bavarian Legation, transmitted copies of the Transactions and Almanac of the Agricultural Society of Bavaria. The thanks of the Council were ordered for the above communications, as also for the Journal of the Statistical Society, the Transactions of the Entomological Society and the American Geographical and Statistical Society, which were placed on the table. The Council then adjourned.

ROYAL GEOGRAPHICAL SOCIETY.

June 13.—A crowded meeting of the above Society took place at Burlington-house, the Earl of Ripon, President, in the chair.

Among those present were the Earls of Airlie and Sheffield, Lord Strangford, Sir Roderick Murchison, General d'Oxholm, Generals Sir G. Pollock, Portlock, Monteith, and Cannon; Admirals Sir G. Back and Gordon; Sir J. P. K. Shuttleworth, Sir H. Willoughby, Sir T. Fremantle, Sir C. Fellows, Mr. T. Bazley, M.P., Mr. H. A. Bruce, M.P., Mr. R. W. Grey, M.P., Mr. A. Russell, M. P., Mr. Danby Seymour, M.P., Mr. J. A. Warre, M.P., the Hon. G. Waldegrave, Captains the Hon. H. A. Murray, Collinson, and Craufurd, R.N.; Colonels Sykes, Everest, Lane Fox, Cocks, and Landon; Majors Stokes and Cooke; the Master of Clare College; Archdeacon Raymond; Messrs. Osborne Smith, C. White, Arrowsmith Findlay, &c.

ELECTIONS.—Lieutenant-General P. De la Motte, C.B., Captain R. F. Burton, Captain W. Fraser Tyler, Professor Hind (of Canada), John F. Bateman, C.E., A. Benson Dickson, Christian Hellmann, Henry Johnson, Coleridge Kennard, Daniel A. Lange, Walter D. Leslie, F. Butler Montgomerie, W. Moon, Stephen W. Silver, and Edward W. Stafford, Esqrs., were elected Fellows.

PROPOSALS.—The Duke of Newcastle, the Earl of Elgin, the Earl of Airlie, the Hon. Robert Marsham, Major Henry Cracroft, Captain Philip D. Margesson, R.A., George Barclay, Fred. W. Bigge, H. Austin Bruce, M.P., R. A. Osborn Dalyell (Consul at Erzeroum), George FitzRoy, William Fryer, Charles P. Grenfell, M.P., W. Vernon Harcourt, H. G. R. Robinson (Governor of Hong Kong), and William H. Smith, Esqrs., were proposed as candidates for election.

EXHIBITIONS.—Specimens of the weapons, manufactures, and natural productions, brought by Captains Burton and Speke from Eastern Africa, and likewise specimens of woods from the Zambesi brought home by Mr. Mc Leod, late Consul at Mozambique, and several maps of the seat of war, &c., were exhibited to the meeting.

The papers read were by Captain R. F. Burton, F.R.G.S., and Captain J. H. Speke, F.R.G.S., on "Explorations in Eastern Africa." A general résumé of the proceedings of the expedition having been given, the subject was divided under three heads—first, in explanation of the map of the country between Zanzibar and Lake Tanganyika, in the interior; secondly, description of the lake itself; and thirdly, discovery of the Lake Nyanza, or sources of the Nile.

An animated discussion followed the reading of the papers in which the President, Sir R. Murchison, Mr. Marqueen, Colonel Sykes, Mr. Danby Seymour, and Captains Burton and Speke took part; and the thanks of the society having been voted to the authors, the meeting adjourned to the 27th instant.

INSTITUTION OF CIVIL ENGINEERS.

May 10 *and* 17.—John Hawkshaw, Esq., Vice-President, in the chair. The discussion upon Mr. Kingsbury's Paper "On the Victoria (London) Docks," and upon Mr. Harrison's Paper "On the Tyne Docks," occupied both evenings. As the papers and the discussion would shortly be published *in extenso* in the "Minutes of Proceedings," it was considered unnecessary to print an abstract of the discussion.

Law Cases.

VICE-CHANCELLOR'S COURT, June 9.—(*Before Vice-Chancellor Sir W. Page Wood.*)

BETTS *v.* MENZIES.

Mr. Rolt, Mr. Hindmarch, and Mr. W. Morris moved on behalf of the defendants that the injunction awarded against them on the 21st of March, 1857, by this Court, to restrain them from importing and selling metallic capsules of the same or the like material as that described in the specification of the plaintiff's patent might be dissolved, and that an inquiry might be directed as to the damages sustained by the defendants by reason of the injunction, and that the amount might be paid to them by the plaintiff.

The patent claimed by the plaintiff in respect of metallic capsules for securing the corks of bottles has been the subject of much protracted litigation, both at common law and in equity, and it will be sufficient to state that upon a recent application to the Court of Queen's Bench for leave to enter the verdict recorded in the second trial for the defendant, the application was on the 30th of May last unanimously granted, on the ground that the plaintiff's patent was bad for want of originality, and was in effect defeated by a patent for a similar invention taken out by one Dobbs as far back as 1804. Under these circumstances the defendants moved to dissolve the injunction.

Mr. Willcock, Mr. T. H. Terrell, and Mr. Webster, for the plaintiff, opposed the motion, and contended that matters ought at least to be left *in statu quo* until the plaintiff's appeal from the Court of Queen's Bench to the Exchequer Chamber had been decided. They also contended that the legal question had been left undetermined by the Court of Queen's Bench, the defendants having raised an extraneous issue upon the construction of the rival specifications of Dobbs and Betts, upon which question alone that Court had given judgment, without adverting to the more material issues in the cause which had been decided by a jury in favour of the plaintiff.

Mr. Hindmarsh replied.

The Vice-Chancellor said that *primâ facie* there were the strongest possible grounds for dissolving the injunction, but the question in reality was whether, until the decision of the appeal from the Court of Queen's Bench, which would be heard in December next, there was such a case on the part of the defendant as would induce the Court to dissolve the injunction in the meantime. The plaintiff, by the concurrent decision of judge and jury, was admitted to be plainly and clearly the inventor of the process. He had also enjoyed for a long time an undisputed possession, until one of his own servants found his way to Belgium, and there described the process. It subsequently appeared that some 45 years before a patent for a similar invention had been taken out by one Dobbs, but everybody supposed that it was the patent of the plaintiff which was being invaded, and the defendant, it would seem, thought so too. There was considerable contest as to whether Dobbs ever did make any use of the invention which he wrote down on paper. It was said that he nor any one else could avail himself of the invention, as he had de-

Digitized by Google

scribed it, until Betts took out his patent. There was evidence on both sides; but, at any rate, the issue was very distinctly raised as to whether Dobbs ever invented it all, and the jury found that he had not. His Honour, after adverting to the proceedings upon the various trials at law, said that, with respect to the recent judgment of the Court of Queen's Bench, it was a matter that weighed greatly with him. He was not sitting to review that decision, nor even to express any opinion upon it. But was there such a *bona fide* ground for an appeal that he ought to allow things to remain *in statu quo* rather than dissolve the injunction? Unless there were strong grounds for showing that the appeal was frivolous and merely interposed for purposes of delay, the Court must uphold the injunction until the trial at law was concluded, and that it was finally concluded could not be said until the appeal was determined. If the case were to be appealed to the House of Lords the question would be different, as there would then be a delay of two years. He was not in the slightest degree saying that the judgment of the Court of Queen's Bench might not be followed by the Exchequer Chamber; but it was to be observed that Lord Campbell stated that it was "after great doubt and deliberation" that he had come to his decision. Then, he confessed, he was unable to follow his Lordship's language in a part of what he stated as a matter of fact upon the specification. He should at once submit to his Lordship's judment as a matter of law, but he could not but think that there had been some misappropriation of facts, or error in the notes of the judgment, and further, that the attention of the judges had been directed to the question of construction of the specifications and that only. As the matter would merely remain undecided for some six months longer, while the plaintiff was confessedly the inventor, and had had the sole enjoyment for a long period, he should not dissolve the injunction. His Honour, after adverting to the circumstance that the defendant was residence abroad, and that with the exception of Clifford, who employed the process for the ornamentation of collins, there was no one else to be found who was infringing the patents, directed the motion to stand over until the hearing of the appeal in the Exchequer Chamber.

COURT OF EXCHEQUER, June 9.—*(Sittings in Banco, before the Lord Chief Baron, Mr. Baron Martin, Mr. Baron Bramwell, and Mr. Baron Watson.)*

HILLS *v.* THE LONDON GAS LIGHT COMPANY.

THIS was an action for infringing a patent, tried before Mr. Baron Bramwell at Guildford during the Summer Assizes last year, when a verdict was found for the plaintiff.

The patent was obtained for certain improvements in the manufacture of gas by taking the subsulphates, the oxychlorides, or the hydrated or precipitated oxides of iron, either by themselves or mixed with sulphate of lime, or sulphate of muriate of magnesia, baryta, strontia, potash, or soda, and absorbing them into or mixing them with sawdust, or peat charcoal, or breeze, or other porous or absorbent material, so as to make a very porous substance easily permeable by the gas. The material was to be put into a purifier and the gas passed through it, depriving it of its sulphuretted hydrogen, cyanogen, and a part of its ammonia, which would be absorbed into the porous material, water being at the same time formed by the union of the oxygen of the oxide and the hydrogen of the sulphuretted hydrogen absorbed. The patent also claimed renovating the material, after it had ceased to purify the gas, by exposure to air.

Mr. Bovill moved for and obtained a rule upon several grounds—1. That the plaintiff's invention was not new, by reason of Croll's and Laming's patents, and the disclosures made by their respective specifications. 2. That the plaintiff was not the inventor on similar grounds. 3. That the plaintiff's specification was insufficient and bad, for not specifying which hydrated oxides of iron would answer the purpose, or for claiming all hydrated oxides of iron, though some would not purify gas. 4. That the mere application of hydrated oxide of iron to absorb sulphuretted hydrogen from gas was not the subject of a patent, its properties and effects with reference to sulphuretted hydrogen being previously well known. 5. That the renovation of hydrated oxide of iron by exposure to air being previously well known, its application to purifying gas was not the subject of a patent.

At the trial several points were raised by the learned counsel for the defendants, and the most important was, that the subject-matter of the plaintiff's patent was not new, it having been disclosed to the world by Mr. Croll, who in the year 1840 took out a [for the purification of gas by the use of black oxide of manganese, or the oxide of zinc and the oxides of iron; and also by Mr. Laming, who in 1847 took out a patent for arriving at the same result by chloride of calcium.

The Attorney-General, Mr. Montagu Chambers, Q.C., Mr. Grove, Q.C., Mr. Hindmarch, and Mr. Charles Pollock now showed cause against the rule; Mr. Bovill, Q.C., Mr. Lush, Q.C., Mr. Webster, and the Hon. G. Denman appeared to support it.

After the Attorney-General and Mr. Chambers had been heard the Court adjourned the further hearing of the arguments until next morning.

JUNE 11.

The arguments for the plaintiff were necessarily very long, and we are compelled to give the substance of them only.

To invalidate a patent on the ground of a prior publication in a specification it was contended that the prior specification must so disclose the invention that the public (that is, that portion of it acquainted with the subject) would be able to practise it without an experiment. If it included, in general terms, matters or processes some of which would succeed and others which would not, then it was not such a publication as would avoid a subsequent patent for the material or process which would have succeeded. In the present case Croll had used the term oxides of iron. Admittedly some of them would succeed, but others would not—that was not disclosing to the public which of the oxides would succeed, and, therefore, if there were no public uses, the public were thrown upon experiment. The plaintiff had discovered the particular oxide that would succeed, and was, therefore, an inventor and entitled to letters patent for his invention. If it were otherwise a person by the widest claim or mere assertion might stop any future inventor from patenting anything within the generality of the assertion. The second specification relied on by the defendants (Laming's) did not indicate that precipitated oxide of iron would purify coal gas; he gave and claimed a mixture as such in which, if taken to operate in the liquid way, precipitated oxide of iron was one of the ingredients; but although he might be entitled to the mixture he had not given to the public the knowledge that precipitated oxides alone would succeed, or were, indeed, the active ingredients, and, therefore, he could not go beyond the mixture he claimed. The plaintiff made the discovery of what really would succeed, and disclaimed Laming's mixture. The plaintiff had really invented and first published an invention which had not been indicated to the public by Laming. That both Croll's and Laming's specifications, when read as a whole, indicated the preparations by the dry way, and, therefore, anhydrous oxides—that was contradicted by the defendants' witnesses at the trial, but the question was one entirely for the jury to decide, therefore the Court ought not to enter a verdict for the defendants or direct a non-suit.

When Mr. Grove had concluded his arguments,

The Lord Chief Baron said that it had made a great impression upon the minds of the Court.

Mr. Bovill and Mr. Lush were heard in support of the rule, when the Court adjourned.

The case will be resumed at 11 o'clock on Monday morning next.

Baron Martin intimated that notice had better be given for sittings in Banco, after term.

COURT OF COMMON PLEAS, Westminster, June 14.—*(Sittings at Nisi Prius, at Guildhall, before Mr. Justice Crowder and a Common Jury.)*

BROWN *v.* OXLEY AND OTHERS.

Mr. Knowles, Q.C., and Mr. Beasley were for the plaintiff; and Mr Hawkins, Q.C., Mr. Karslake, and Mr. Brandt for the defendants.

This was an action brought by an architect to recover a large sum of money from the defendants, who are the patantees of a peculiar kind of wheel for the manufacturing of which they had taken premises at King's-cross.

Mr. Knowles having opened the case to the jury, it became clear that the case would be more efficiently disposed of by an arbitrator. It was accordingly, after some discussion, referred to Mr. Serjeant Hayes, with full powers to state a case for the opinion of the Court on any points of law which might arise, if he should think fit.

SECONDARY OFFICE, Basinghall-street,—*(Before Mr. Potter.)*

CARTER *v.* COCKHEAD.

Counsel, Mr. Powell; Solicitors, Messrs. Langley and Gibbon. In this case it was decided that the user of a patent was liable to the patentee in the shape of royalty if he persisted in using the invention after receiving notice of its being an infringement of a patent. The alleged infringement was "The surrounding a gas light with cut glass drops." The jury gave a verdict for £21, being £1 per annum per light royalty; the defendant having used seven lights thus surrounded for three years.

Our Weekly Gossip.

WE understand that in order to have an authoritative investigation into the whole question of lighting public galleries with gas, the Lord President of the Council has named a commission of inquiry, consisting of Professors Faraday, Hofmann, and Tyndall, with Mr. Redgrave, R.A., and Captain Fowke, R.E., who will commence their investigations immediately.

Our recent article urging the laying down of a direct Mediterannean line of submarine telegraph has had, we are happy to say, its legitimate effect. The *Daily News* of Tuesday last, in its City article, says:—"The existing war on the Continent places in so striking a light the importance of securing a means of telegraphic communication with the British possessions in the Mediterranean, totally independent of any continental medium, that we have much satisfaction in stating that Government have entered into arrangements for laying down, as speedily as possible, a telegraphic cable direct from Falmouth to Gibraltar—a distance of 1,100 nautical miles. Tenders will shortly be invited for the manufacture of the requisite length of cable. Meanwhile, the Gutta Percha Company are already engaged in preparing the covering for it. The engineers charged with the carrying out of this important Government undertaking are Mr. Gisborne and his associates, and it is believed that by August next considerable progress will have been made. With regard to the motives of Government in thus departing from the ordinary practice of employing the agency of a public company, some curiosity will be felt. Messages on the service of the State will of course have priority over all others; but as the undertaking will be constructed with the money of the nation, a proper degree of attention must be paid to commercial requirements. It is surmised that the authorities may, perhaps, contemplate handing over the line, when completed, to be worked or leased by a public company or other parties. A decided defect is involved, however, in the existing arrangement that the cable shall contain only one wire, the more especially as, although the line is at present to be carried only to Gibraltar, its ultimate extension to Malta and Alexandria, there to form a junction with the wires to India, is certain and not remote. Until this comprehensive scheme is carried out, there will be no real security for interests of vast national importance, nor will Government be making a proper use of the invaluable appliances placed at their command by modern science."

Notwithstanding that the establishment of Woolwich Arsenal engaged in the various departments of war has for some time exceeded that of any former period, large additions have been made every day during the past week, consisting principally of men required for preparing guns, shot, shell, and cartridges, for use and for exportation, removing stocks of obsolete or doubtful stores to be examined and recast, and cleaning and burnishing arms and materials of every description which may possibly be brought into sudden requisition. The *Times* correspondent furnishes the following particulars:—The number of men, women, and lads who daily assemble within the Arsenal at the various working hours, including the contractor's labourers, are calculated at about 12,000 persons. The Royal carriage department and the laboratory employ 6,718 military and civil officers, managers, masters, foremen, artificers, labourers, and others; the gun factories, the military storekeepers, and the inspectors of machinery, about 2,000; the other departments each a proportionate number, and the contractors about 3,000. A large building is in course of erection at the terminus of the new railway junction in the Arsenal, to be used as a store reception room. The length of the building is stated to be 272 feet, and the breadth 72 feet. The contract has been granted to Mr. Myers, who recently built the pattern room attached to the carriage department. The new branch of Sir W. Armstrong's rifled ordnance department, under contract by Messrs. Lucas Brothers, is progressing rapidly; the tall chimney, intended to serve the machinery, and to be 100 feet high, is far advanced, and the exterior walls of the factory are ready to receive the iron girders to lay down the first floor. The old Lancaster shell factory, adjoining the building now in progress, is employing 180 smiths, hammermen, and others, and on Saturday commenced forging the coils to carry out the manufactory of the new rifled ordnance as far as the limits of the present establishment will admit.

NOTICES.

The MECHANICS' MAGAZINE will be sent free by post to all subscribers of £1 1s. 8d., annually, *payable in advance*. Post Office Orders to be made payable to R. A. Brooman, at the Post Office, Fleet Street, London, E.C.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 5d. per line for any number of insertions less than 13; for 13 insertions, 4d. per line; and for 52 insertions, 3d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

Special Arrangements for larger or Serial Advertisements. To ensure insertion, Advertisements must reach the Office by 5 o'clock on Thursday evening each week. None can be received after that time for the ensuing number.

The demand for Mr. E. J. REED's paper—

ON THE MODIFICATIONS WHICH THE SHIPS OF THE ROYAL NAVY HAVE UNDERGONE DURING THE PRESENT CENTURY, IN RESPECT OF DIMENSIONS, FORM, MEANS OF PROPULSION, AND POWER OF ATTACK AND DEFENCE,"

has been so great that the Journal of the Society of Arts, the MECHANICS' MAGAZINE, and all other Scientific Journals in which it appeared in December last, are now out of print. The demand still continuing, it has been deemed desirable to reprint it in a separate form. An 8vo. edition of it, in large type, and on fine paper, has, therefore, been prepared, and may now be had at the Office of this Magazine, price 1s.

THE SCREW STEAMER COLOMBO.

THE Colombo, one of the fine screw steamships belonging to the Peninsular and Oriental Company's fleet, left Southampton Docks on Wednesday, in charge of acting-captain J. Laing, for the measured mile in Stokes Bay, to undergo an official trial before resuming her place in connection with the mail service. This vessel, which is about four or five years old, was sent round to Liverpool in September last for the purpose of being lengthened at Mr. Laird's building yard at that place. She was cut asunder, and lengthened 42 feet midships, making her present length 335 feet over all. New boilers, on Lamb and Summers's patent, have been put in, and fitted with Mr. Andrew Lamb's patent superheating steam apparatus. Her fore cabin is lengthened, new iron fore and main masts erected, and several other improvements effected, making her one of the most convenient and comfortable vessels in the Company's service. By the alterations which have been made in the Colombo, she now has capacity for 200 tons of cargo, 200 tons of coal, and 50 passengers more than she before possessed, while the external appearance of the vessel is considerably improved. Several scientific and other gentlemen were on board to witness the trial. The first run at the mile was made in 5 min. 18½ sec.; second, 4 min. 24 sec.; third, 5 min. 9 sec.; fourth, 4 min. 33 sec. The mean speed was 12½ knots per hour, being a slight increase on her former rate before the alterations were made; steam pressure, 18lb.; vacuum, 25 in.; revolutions, 26. Her draught of water was 16 ft. 11 in. forward; 19 ft. 6 in. aft. Weight of coals on board, 789 tons; ditto water, 50 tons; other stores, 20 tons. The Colombo is propelled by a pair of balance beam engines (by Napier, of Glasgow), which drive a geared screw, and which revolves three times to every revolution of the engines. She is fitted with two steam winches, which are available for working the fire pumps, disposal of cargo, weighing anchor, or overcoming a leak; but this machinery can be worked either by hand or steam. The deck forms a magnificent promenade, and the whole of the internal arrangements are of the most perfect character. She is bark-rigged, and can carry a considerable spread of canvas. The Colombo will leave Southampton for Alexandria on Monday next, with the East India and China mails.

The Submarine Telegraph Company are about to submerge a cable from Weybourne, on the Norfolk coast, to Tonning, on the shores of Denmark. The cable, which will comprise three wires, will be 388 miles in length, and will be supplied by Messrs. Glasse, Elliott, and Co., who seem to be doing their utmost to "put a girdle round the earth," although the operation takes more than 40 minutes. The line is expected to be completed in the course of the ensuing month.

Patents for Inventions.

PROVISIONAL PROTECTIONS.

Dated May 18, 1859.

1234. J. Brennand, of Manchester, Calico Printer. Certain improvements in the construction of carriages for the conveyance of passengers, goods, and minerals, and also in the apparatus for propelling the same.

Dated May 21, 1859.

1258. T. S. Cressey, of Burton-on-Trent. Improvements in machinery for cutting staves for casks.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(*From the London Gazette, June* 14, 1859.)

287. R. Gormully. Piano-fortes.
296. E. E. Allen. Stereoscopic apparatuses.
305. G. Leach. Leashing and winding yarn.
311. J. Petrie, jun., and T. Wrigley. Paper.
316. W. Thompson. Printing telegraph.
321. R. A. Brooman. Shirts. A communication.
323. F. H. Maberly. Obtaining spring power.
327. W. R. J. Packer. Ploughshare.
331. F. H. Maberly. Corking, taps, bottles, &c.
338. G. F. Chantrell. Charcoal.
341. W. H. Crispin. Atmospheric and hydraulic engine.
343. J. Lee. Cranks.
356. J. B. Redman. Carriage ways.
361. E. Wilkins. Flower vases.
370. W. E. Newton. Refining sugar, &c. A communication.
371. E. Herring. Alcohol.
375. J. G. Taylor. Writing materials.
376. W. A. Covert. Railway switch. A communication.
378. G. L. Stocks. Steering apparatuses.
388. R. Cogan. Crushing and mixing.
393. G. Hadwen and J. Wadsworth. Jacquard apparatus.
395. T. Willis and G. Chell. Spinning, &c.
398. S. H. Huntly. Cooking apparatus.
399. T. White and G. Jenkins. Raising and lowering ships.
407. W. E. Newton. Sewing machines. A communication.
408. J. Parkinson. Coffins.
451. C. Garton. Treating cane sugar.
461. W. Clay. Beams and bars.
462. W. Basford. Bricks and tiles.
520. J. H. Johnson. Stopping horses. A communication.
547. P. Currie. Spindles for locks, &c.
617. A. V. Newton. Rolling horse shoe iron. A communication.
742. G. Neal. Gas apparatus.
741. J. H. Johnson. Sheet tin. A communication.
833. T. Richardson and G. W. Jaffrey. Harbours of refuge, &c.
848. A. Shanks. Forging metals.
851. L. Brierley and H. Geering. Ornamenting furniture.
1030. J. Higgin. Treating madder.
1035. W. Bayliss. Iron-hurdles and fencing.
1200. R. Gourlay. Moulds for casting.
1250. J. P. Budd. Tin and terne plates.
1263. W. Cram. Printing and dyeing.
1275. A. V. Newton. Washing machine. A communication.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed June 10, 1859.

2836. A. Barclay.
2837. C. Hodgson.
2849. A. Rollason.
2850. J. A. Carruthers and T. Blackburn.

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

STEAM ENGINES, &c., 2522, 2530, 2545, 2548.
BOILERS AND THEIR FURNACES, 2549, 2556, 2558.
ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 2532, 2569, 2573, 2576.
SHIPS AND BOATS, including their fittings, 2524, 2531, 2537, 2575.
CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 2591.
FOOD AND BEVERAGES, including apparatus for preparing food for men and animals. *None.*
FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 2534, 2539, 2543, 2544, 2557, 2562, 2579, 2581, 2589, 2590, 2592, 2593.
BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c., 2535, 2585, 2591.
LIGHTING, HEATING, AND VENTILATING, 2523, 2527, 2559, 2578.
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 2541, 2545, 2553, 2560, 2587.
METALS, including apparatus for their manufacture, 2525, 2540, 2547, 2565.
CHEMISTRY AND PHOTOGRAPHY, 2554, 2561.
ELECTRICAL APPARATUS, 2580, 2584.
WARFARE, 2564, 2577.
LETTER PRESS PRINTING &c. *None.*
MISCELLANEOUS, 2521, 2523, 2528, 2529, 2533, 2536, 2538, 2542, 2546, 2550, 2551, 2552, 2555, 2563, 2566, 2567, 2568, 2570, 2571, 2572, 2574, 2582, 2583, 2585, 2586, 2595.

2521. G. SCHMIDT. *Improvements in the construction of core bars.* Dated NOV. 10, 1858.

This consists in combining together the several sections into which a core bar is divided longitudinally, by hinging them each at one extremity to an end piece or plate, so that each section can move inwards on its hinge towards the central line or axis of the bar. *Patent abandoned.*

2522. E. HUMPHRYS. *Improvements in steam-engines and boilers.* Dated NOV. 10, 1858.

In arranging steam-engines for propelling vessels by screw propellers the patentee combines with ordinary low pressure cylinders fixed in a horizontal or inverted position, other cylinders of smaller size, which are to work at a higher pressure than the low pressure cylinder, and in connection with it in the manner known as Woolf's system. The piston rods of the low and of the high pressure cylinders are so coupled together as to convey the power to a single shaft through a single connecting rod, and they are enclosed together in a steam jacket. Before the steam is admitted to the high pressure cylinder it is superheated by passing it through heating apparatus. *Patent completed.*

2523. G. SCHMIDT. *Improvements in the manufacture of cast iron pipes.* Dated November 10, 1858.

In constructing the moulds a hollow iron pattern is employed, and this is laid on a table and secured to it by bolts; the top of this table is hollowed out to allow just one half of the pattern to descend below its upper surface. If the hollow formed in the table is wider than the diameter of the pattern, the extra space is filled by strips of wood put in on each side; on to the table and over the pattern a rectangular frame is placed, the ends of which are arched to pass over the ends of the pattern; the width and length of the opening in this frame are about one inch greater than the diameter and the length respectively of the pipe to be made. The portion of the pattern above the surface of the table is then covered all over with a suitable thickness of loam, the loam being brought to a uniform thickness by a bar or template moving about the central axis of the pattern; this coating of loam is dried by turning steam into the interior of the pattern, which is closed at the end and connected with a steam-pipe. When the loam is sufficiently set the rectangular frame is to be lifted up so as to withdraw the half mould of loam from the pattern, but before this is done (and before the loam is

Digitized by Google

dried) it is closed in at the two ends by arched plates or castings, which are fixed by bolts or keys to the curved ends, and also to the straight sides of the rectangular frame, and on these plates or castings are fixed bars connecting together the two end plates, and bearing on the surface of the loam. The bars are held against the loam at several points in the length of the pipe by semicircular pieces passing over the mould and attached to the two sides of the rectangular frame. After the half mould has been removed from the pattern and been dried, the interior surface is finished, blacked, and again dried, and then two of the half moulds, with their supporting frames, plates, and bars, are clamped together, and a core introduced between them; afterwards the casting is effected in the usual manner. *Patent abandoned.*

2524. A. J. BROOKS. *An improvement in screw propellers.* Dated November 10, 1858.

The object here is to prevent slip. The invention consists in adding to the face of an ordinary screw propeller blade one vane, or two or more vanes on each side of the axis. One vane is fixed at the outer extremity of each blade and is shaped and fitted so as to prevent the water flying off by centrifugal action from the ends of the blade. The peculiar feature of the invention consists in employing vanes in the form of segments of cylinders concentric with the axis of the propeller and included between the propelling face of the blade and a plane passing through the aftermost edge of the blade at right angles to the axis. *Patent completed.*

2525. G. SCHMIDT. *Improvements in ladles employed when casting metals.* Dated November 10, 1858.

This consists in so arranging the ladles as to prevent the scum or slag passing with the metal into the mould when pouring. This object is effected by placing a partition in the ladle, leaving a space between the lower edge of the partition and the bottom of the ladle. When the metal is tapped into the ladle it is allowed to run into one of the two divisions, and in pouring the metal from the ladle it is poured from the other division, the metal passing under the partition. *Patent abandoned.*

2526. E. LOCKE. *Improvements in the construction of gas meters.* Dated November 10, 1858.

Here the inventor mounts the measuring drum of wet gas meters in a swinging frame, and keeps it at a determinate height with respect to the water level, by supporting it by a float. The frame which carries the drum may be forked and jointed to the meter-case, and the float may be connected with the bearings or with the axle of the drum. The motion of the drum is communicated to the counting apparatus by means of a deep-toothed pinion, which allows for the rise and fall of the drum. At both the entrance and exit side of the meter he proposes to insert slips of glass into the case for showing the level of the water and to remove from the glass any deposit that might hide the water level. He applies a wiper (made of sponge) to the inner surface of the glass by a rod which passes through the case. Thus, when an inspection is required, the wiper may, from the outside of the meter, be drawn over and caused to clean the glass, so as sufficiently to exhibit the water level. *Patent abandoned.*

2527. C T. JUDKINS. *Improvements in gas regulators.* Dated November 10, 1858.

This relates to two previous patents of the patentee. He now fixes a bar across the regulator, and suspends to such bar a balance lever-rod at right angles therewith, and connects one end of such balance-rod with the disc or with the spindle of the valve, which is nearer the end of the regulator at which the outlet is situated than hitherto, and a weight or counterpoise slides or screws on or is otherwise connected with the other end of the balance-rod, so that, by moving such weight to or from the point of suspension of the balance-rod, the amount of pressure at which he intends the valve in the inlet chamber to be closed is regulated. *Patent completed.*

2528. J. BLETHYN. *Improvements in the manufacture of fuel.* Dated November 11, 1858.

This consists of an amalgamation of small anthracite coal or dust with small bituminous coal, and coal tar, pitch, and water in certain definite proportions. *Patent completed.*

2529. J. and W. LEES. *An improvement in the construction of oil cans.* Dated November 11, 1858.

This consists in constructing oil cans with an air tube, reaching from near the bottom thereof to within a short distance from the end of the spout through which the oil is delivered; both the air and delivery tubes are fixed to the lid, and they are surmounted by a case into which any oil that runs down the delivery spout is collected. Thus the oil cannot escape from the oil can when it is lying down, and the can may be filled until the oil nearly reaches the lid. *Patent completed.*

2530. R. WRIGHT and T. J. MERCER, jun. *A new or improved motive-power engine.* Dated Nov. 11, 1858.

This consists of an engine in which motive power is obtained by compressed air, which engine also effects the compression or condensation of the air, by the expansion of which the power is obtained. The engine consists of the following parts:—A series of condensing pumps communicate with a cistern or reservoir provided with a safety valve. The piston rods of the pumps are connected by rods and clips with a series of eccentrics situated on the main shaft of the engine. The eccentrics are so fixed on the shaft that the strokes of the pumps follow each other in regular succession, and a uniform density is maintained in the condensed air in the reservoir. The condensed air is conducted into a cylinder similar to the cylinders of a steam engine, where it acts upon a piston in the same way as steam. *Patent abandoned.*

2531. F. H. MABERLY. *Improvements in the construction of ships of war and other vessels, their machinery and appurtenances.* Dated November 11, 1858.

This invention is not described apart from the drawings. *Patent completed.*

2532. M. BENSON. *An improved manufacture of rails for railways.* (A communication.) Dated Nov. 11, 1858.

This relates, 1, to means for constructing the improved rail, and consists in furnishing rollers with a combination of grooves of certain proportions, so that a rail made by a portion of them will resemble a V-rail in shape in its transverse section; and the rail thus made, by being passed through other grooves, will be converted into the shape of a hollow T-rail. Other operations are then performed, but these, with other parts of the invention, are not described apart from the drawings. *Patent completed.*

2533. A. V. NEWTON. *Improved apparatus for securing doors of safes, closets, and apartments.* (A communication.) Dated November 11, 1858.

This relates to locking the doors of bank safes on the inside automatically by latching bars operated by a clock-work movement; and to the locking or unlocking the doors of rooms in hotels, &c., by combining an auxiliary bell-pulling wire with the ordinary bell-pulling wire of the room. *Patent completed.*

2534. T. GRAY. *An improvement in separating wool and animal fibres from vegetable fibres contained in mixed fabrics.* Dated November 11, 1858.

This consists in soaking such mixed fabrics in water, so that the animal fibres therein may be filled with water before subjecting the mixed materials to the action of acids. *Patent abandoned.*

2535. J. RAE. *Improvements in cisterns suitable for containing water for household uses.* Dated Nov. 11, 1858.

The patentee employs a four-sided cylindrical or other form of vessel, having a bottom which inclines in every direction towards a central point, and at this point an opening is formed from which a pipe leads to the closets of the house, and by this pipe any sediment is carried away. Within the cistern is arranged a filter, consisting of a vessel having an opening in the top which is filled by a sponge, to prevent the solid impurities of the water from entering. In the interior of the vessel is a perforated plate on which beds of filtering material rest, those employed being first a bed of sand, then one of charcoal, and afterwards another one of sand. From the lower part of the filter, under the perforated plate, a pipe passes to the exterior of the cistern and terminates in a tap, through which filtered water may be drawn. The cistern is also furnished with a tap for drawing unfiltered water. *Patent completed.*

2536. A. MICKELTHWATE. *Improvements in treating and manufacturing buffalo and other horn, so as to be used as a substitute for whalebone, and for other useful purposes.* Dated November 11, 1858.

The inventor first soaks the horne in urine, potash, or other alkaline leys, for several days. He then splits the horn in breadths, warms the outsides over a fire, and then places it in a press, so that the inside of the horn shall go against a metallic surface, the outside of the horn having a pad of leather or horn shaving put over it. This process is for straightening the length of horn before entering the cutting machine. The horn lengths are then boiled or steamed, and when sufficiently soft pass through rollers, which are hollow to admit iron heaters or steam, to keep the rollers hot. The horn then comes in contact with knives or cutters, and is cut into shreds or breadths of the required thickness. *Patent abandoned.*

2537. J. BUCHANAN. *Improvements in propelling vessels, ships, and boats.* Dated November 11, 1858.

This relates to former patents dated 18th September, 1856, and 6th July, 1858. A central enclosed paddle-wheel or propeller is contained in a channel or recess in the vessel's bottom, but no provision was heretofore made for securing a feathering action for the floats or actual propelling surfaces. This is provided for in the present invention by an automatic action, which causes each float to turn upon its vertical centre or joint. The feathering action is also intended for use in side or other paddle-wheels. *Patent abandoned.*

2538. T. F. COCKER. *Improvements in the manufacture of steel and iron wire, also of sheets and strips of steel.* Dated November 12, 1858.

This consists in immersing such wire, or strips, or sheets when in a heated state, as taken from the annealing pot or oven, in hot water, hot lime and water, or in oil, or other liquid in a heated state. *Patent completed.*

2539. J. OGDEN. *Improvements in shuttles for looms.* Dated November 12, 1858.

The inventor makes the shuttles totally of steel, homogenous metal, malleable iron, brass, copper, or like metal, instead of making them of wood and metal. *Patent abandoned.*

2540. J. G. MARTIEN. *Improvements in the manufacture of iron, and in the apparatus employed in such manufacture.* Dated Nov. 12, 1858.

The patentee according to this specification overcomes many difficulties in connection with the manufacture of iron, and keeps the puddling furnace supplied with the required quantity of deoxydized ore, so as to maintain a continuous working in the puddling furnace, 1. By a novel mode of constructing, arranging, and working the deoxydizing chambers. 2. By an arrangement of parts whereby the contents of the deoxydizing chambers may be discharged with greater facility than heretofore. 3. By an improved mode of supplying air to the combustible gases evolved from the puddling furnace, and whereby the oxydizing chambers are heated. 4. By a mode of arranging and operating the dampers in the flues so that the heat in the apparatus may be regulated with facility, so as to retain it in contact with the deoxydizing chambers when required, and prevent it from escaping when the puddling furnace is not at work. *Patent completed.*

2541. D. TURNER. *Improvements in the manufacture of wood soles for clogs, boots, and shoes.* Dated November 12, 1858.

This consists in cutting each block or piece of wood into two pieces so as to leave a projection in the under side of each piece to form a heel, and then to bend the part of each piece beyond the heel by dies, plates, &c. The wood before being subjected to pressure is steamed, and is held under pressure until it is set to the shape desired. *Patent abandoned*

2542. G. T. BOVEFIELD. *An improved apparatus for illustrating conic sections and the lines of the globe.* (A communication.) Dated November 13, 1858.

This consists in mounting the globe with an extended tubular horizon and moveable graduated meridians made of materials transparent, translucent, or opapue, capable of being written on with a pencil, and of having the writing or work easily wiped off. In connecting with the globe a surface divided into zones, &c., capable of being marked upon with a pencil, and of having the writing easily rubbed off. In having the hollow cone so constructed that the pole may be elevated, so as to mark the visible horizon for any latitude, or to mark the ecliptic. And when resting in a horizontal position to mark the meridians all by holding the globe steadily in its position, and drawing the pencil around on the edge of the extended horizon, and in that the pencil may rest on the proper point of that horizon. The globe is revolved to draw the equator and all circles parallel to it, and in having the segment of the cone cut into conic sections for illustrating the ellipse, the parabola, and the hyperbola. *Patent completed.*

2543. M. N. MILLS and N. SIDEBOTHAM. *Certain improvements in looms for weaving.* Dated Nov. 13, 1858.

This relates chiefly to looms for weaving fabrics, and consists, 1, in working the jacquard cylinder of the pattern card by an improved-shaped cam fixed to the cam or tappet-shaft. 2. In making the hooks of the jacquard to swivel on centres; these hooks may be taken down from the top by a lever or knife, or the shed may be divided in the centre by two levers, the said levers or knife for forming the shed being worked by a single or double tappet or eccentric. 3. In the application of elastic bands to the shafts or healds of looms for raising them after they have been drawn down by the shaft motion or otherwise. *Patent completed.*

2544. J. BENYON and J. W. B. BOWDEN. *Certain improvements in looms for weaving.* Dated Nov. 13, 1858.

This consists in working the healds from below by bottom jacks or tappet-levers of the usual construction, which are connected by rods to the lower side of the healds. The healds are secured in rigid frames guided at the sides or otherwise. *Patent completed.*

2545. J. WADSWORTH. *Improvements in the construction of moveable or adjustable heels for boots and shoes, and of spurs adapted thereto, and to be used therewith.* Dated November 13, 1858.

The patentee claims, 1, a method of uniting or joining the moveable to the fixed part of the heels by rings and discs with interlocking flanches. 2 A method of constructing spurs, and attaching the same to the moveable heels by hoops forming parts of the said spurs, and adapted to encircle the rings of the moveable heels. *Patent completed.*

2546. W. ASHTON and T. CARTMELL. *Improvements in air-pumps, part of which improvements is also applicable to the pistons of other pumps and of steam-engines.* Dated November 13, 1858.

This consists, 1, of a double acting air-pump for condensing steam-engines. The patentees employ two condensers, one connected to an exhaust pipe leading from the steam cylinder above the piston, and the other connected to a similar pipe leading from the said cylinder below the piston, and each furnished with a separate injection cock. A pipe from the lower part of one of these condensers communicates with the lower part of the air-pump cylinder below the bucket or piston, and a similar pipe from the lower part of the other condenser communicates with the upper part of the air-pump cylinder above the bucket or piston. Each of these pipes has a valve opening only towards the air-pump. The air-pump cylinder has two delivery pipes, one at or near the top, and one at or near the bottom thereof. These two delivery pipes each have a valve opening only from the cylinder. The air-pump is thus double acting. Each of the exhaust pipes leading from the cylinder to the condensers has a vacuum valve provided with a hand lever. This valve may be opened when required to let air into the exhaust pipe when the steam is cut off, and thus prevent the rising of the water into the steam cylinder. It relates, 2, to the packing of pistons. The packing consists of two outer slightly eccentric rings, which are divided at their thinnest part so as to give equal elasticity throughout their circumference, and are conical upon their inner surfaces, and two inner spring rings (also eccentric and divided) conical upon their outer surfaces. These inner rings have a constant tendency to expand, and are furnished (in the interior) near their ends or points of division with lugs or ears through which a screw bolt passes. When the piston is first put in the cylinder the ends of the spring rings are drawn close together by the nut, which is then slackened to allow the springs to exert their elasticity as much as required. There is a nut also on the screw between the lugs to keep the spring expanded. *Patent completed.*

2547. J. COURAGE and F. BENNETT. *Improvements in furnaces for reducing and smelting ores, scoria, slag, and waste.* Dated November 13, 1858.

The object here is to utilize the heat which is ordinarily allowed to pass off into the atmosphere from the slag hearth, or from the cupola furnace employed in the reduction or smelting of ores, scoria, and slag, by rendering it available for the reduction of the "waste" from ores. The invention consists, 1, in constructing, in connection with the hearth or furnace, a horizontal or nearly horizontal furnace or bed upon which the waste is laid, and over which the products of combustion from the hearth or furnace are conducted for partially or wholly reducing the waste. 2. In regulating the degree of heat applied to the said waste by a supplementary fire or furnace constructed with one or more of the improvements described in the specification of a patent granted to the said John Courage, dated 25 May, 1858. *Patent completed.*

2548. J. TAYLOR. *Improvements in portable steam-engines.* Dated Nov. 13, 1858.

This consists in constructing an engine with its boiler upon a framing which is mounted upon wheels of suitably large diameter and breadth of face. The patentee supports the fore end on wheels of smaller diameter, and when he

Digitized by Google

employs six wheels he couples or connects the axles of the two leading wheels and the two trailing wheels together by suitably arranged connecting bars, braces or rods crossed longitudinally, the hind near wheel axle being connected to the fore off side axle, and *vice versâ*, so that the direction of motion of the leading wheels being changed, the trailing wheels follow in the two bearing or driving wheels, whilst the two leading wheels are suitably mounted to swivel or turn, to change the direction of the engine by a steering wheel. This and other features of the invention require reference to the drawings. *Patent completed.*

2549. D. AULD. *Improvements in furnaces and boilers, and in the generation and treatment of steam.* Dated Nov. 13, 1858.

This consists, 1, in an arrangement of water spaces and tubes in connection with the boiler and furnace, for supplying the air to the burning fuel in a heated state, and in a properly subdivided condition, so as to embrace the whole of the burning mass upon the furnace bars, whereby wasteful emission of smoke is prevented and combustion efficiently maintained. The invention consists, 2, in a mode of increasing the efficiency of steam, by passing it on its way from the boilers to the working cylinders of the engine, or other apparatus through an arrangement of pipes disposed in the discharge flues of the boiler. *Patent completed.*

2550. M. SWAN. *Improvements in the construction of floating docks and other floating structures.* Dated Nov. 13, 1858.

According to this invention, when applied to the construction of floating docks, it is proposed to construct the dock of two or more pontoons, connected at their lower or under ends by strong girders supporting a cradle, the space between the two pontoons being sufficient to receive a ship. The details of the invention may be variously modified. *Patent abandoned.*

2551. L. PETRE. *Improvements in the application of glass to ornamental and useful purposes.* Dated Nov. 13, 1858.

This consists in the use of glass having ornamental or other subjects prepared on the one side, the ornament or subject of such preparation being visible through the glass while the glass adheres to walls or other surfaces. *Patent completed.*

2552. I. LIVERMORE. *An improvement in the manufacture of shuttlecocks.* Dated November 13, 1858.

Here vulcanized india-rubber is applied to the under surfaces of a shuttlecock, in which the feathers are stuck. *Patent completed.*

2553. M. L. J. LAVATER. *Improvements in the manufacture of mats, coverings for floors and other surfaces, and other cellular articles when india-rubber compounds are used.* Dated November 13, 1858.

This consists in rolling out sheets of india-rubber compounds, each of the thickness desired for the depth of the cells of which the finished article is to consist. The patentee then, by suitable punchers or cutters, removes portions of such sheets, leaving other portions to form the walls or sides of the several cells of which the article is composed. There are modifications included. *Patent completed.*

2554. C. J., T., H., and C. THOMAS. *An improvement in the manufacture of caustic alkaline lees.* Dated Nov. 13, 1858.

This consists in pumping or running the ordinary black-ash liquor into a pan or vessel, to which is added the necessary quantity of lime for causticizing such black-ash liquor. The patentees then boil the liquor and lime, and at the same time force atmospheric air, by preference in finely divided streams, through and amongst the liquor, by which operation the liquor is purified and causticized. *Patent completed.*

2555. A. B. WOODCOCK and J. M. DUNLOP. *Improvements in covering rollers, shafts, and tubes of any figure or material with elastic shells or covers, with vulcanised india-rubber or other elastic substance, and in turning or grinding the surfaces of such elastic covers or shells.* Dated Nov. 13, 1858.

The elastic shell or cover is distended by forcing water or other fluid into it, and while so expanded the roller, &c., is introduced into the shell, or the shell or cover is drawn on to the roller, &c., by screws, &c., the fluid being allowed to exude as the roller, &c., enters by a valve or tap. Afterwards to finish the surface of the elastic shell, so as to reduce it truly to the desired form, the covered roller, &c., is (if circular in section) put into a lathe having a file or files, or other cutters or tools, which come in contact with the elastic surface. While the roller, &c., revolves, the files or tools are caused to traverse by a screw; or if the roller, &c., is square or flat-sided, the files, &c., are traversed over the surfaces, while the roller, &c., is fixed, the files, &c., being carried by a slide moved backwards and forwards, by a crank, &c.; or the tools may be stationary, and the elastic shells moveable. *Patent completed.*

2556. D. FRODSHAM. *Improvements in apparatus used in combination with fire-boxes of tubular steam-boilers in order to supply air and steam thereto.* Dated Nov. 13, 1858.

On the interior of the opening into the fire-box is a hinged plate which, when it hangs vertically, closes the said opening. This plate has angular plates at the sides to prevent the air passing sideways into the fire-box. A hinged door is also employed on the outside of the fire-box. Two bell-mouthed tubes passing under the fire-box and having their bell-mouths so placed as to catch the air, supply air to a perforated tube just below the feed opening; streams of air are thus introduced over the ignited fuel. Jets of steam are introduced in a similar manner by a perforated tube in connection with the steam chest. *Patent completed.*

2557. M. PULLAN. *Improvements in machinery for drying yarns and other materials.* Dated Nov. 13, 1858.

This relates to drying yarns, &c., in the form of hanks or endless bands, by heated cylinders, to which rotary motion is imparted. The yarn, &c., being placed over such cylinders and held at tension thereon, will be carried round by their revolution, and a continuous heating surface being thus presented to the travelling band or hank, the moisture will be quickly evaporated therefrom. *Patent completed.*

2558. J. A. HOPKINSON. *Improvements in steam-boilers.* Dated November 13, 1858.

This consists in the adaptation of curved pipes placed in the furnaces, flues, or chambers of steam-boilers, which effect a continued and uninterrupted circulation of water in the boiler, and through the tubes to the upper side of the flue or flues, so long as heat is applied, that circulation being applied independent of pumps or valves or other such means. Also in fastening pipes or tubes in boilers by an adjustable plain conical or threaded hoop, screwed on the outer end of the pipe, fitting a suitable hole in the boiler, and holding the pipe fast in place by a nut and screw. *Patent completed.*

2559. S. ST. C. MASSIA. *A new economical guard for candles and wax-lights.* Dated November 15, 1858.

This guard is made generally of tin, and must be of the same circumference as the light or candle to which it is to be adapted. The bottom part of the guard has the form of a saucer, which must vary in size according to the circumference of the candle for which it is to be used. The middle part of the saucer has a hole in it, in which rises a tube or chimney through which the wick passes. The tube or saucer are pressed out of one piece of metal. The invention is not fully described apart from the drawings. *Patent abandoned.*

2560. T. R. BUTCHER, F. STEVENS, W. T. JOHNSON, and T. JARVIS. *Improvements in the hammer-rails of pianofortes.* Dated November 15, 1858.

Instead of placing each butt between two of the metal prongs, as heretofore, the inventors construct them so as to work over or to embrace the prongs, that is to say, the butts are made of a greater width, slots being formed in the bottoms of the butts, instead of the ordinary back hole, so that each butt embraces one of the metal prongs, the series being connected in the ordinary manner by means of a wire passing through the whole length of the plate. They also construct the metal prongs themselves of a much greater width than has been previously done, thus giving increased firmness, while the construction and arrangement of the butts, as before described allow a greater amount of freedom of action as well as firmness to be attained, the result being that the touch is lighter, and that the hammers strike with greater precision and certainty. With respect to the metal of which the plate is constructed, they state that although brass or any other suitable metal may be employed, yet they prefer the use of zinc, the latter metal being much more economical than brass; but it must be distinctly understood that they do not claim the use of any particular metal for this purpose. *Patent completed.*

2561. A. DICK. *A new or improved manufacture of a yellow pigment.* Dated November 15, 1858.

This yellow pigment is manufactured from the dross or oxide produced in the process of softening lead, by heating the said dross or oxide in contact with air, whether the said dross or oxide be treated with common salt or any of the acids before enumerated, before, during, or after the heating, or be heated without the use of common salt or any of the said acids. *Patent completed.*

2562. G. DAVIES. *Improvements in the process of finishing piled fabrics, and in apparatus employed in such process.* (A communication.) Dated November 15, 1858.

This relates principally to finishing piled fabrics, whether woven or felted (called "astracan cloths"), and consists of two parts:—1, the machinery for friezing or curling the pile or nap; and, 2, the process of fixing and pressing the "curl," dyeing, embossing, and finishing the fabric. The construction of the friezing machine is as follows:—The main driving shaft carries a spur pinion, which, by gearing with a similar wheel, drives a shaft carrying a drum or band pulley, which actuates two sets of spindles by endless bavels. The end of the drum shaft carries a bevil wheel which, by a vertical shaft and other wheels, drives another drum or band pulley at the upper part of the machine, which being furnished also with endless bands, actuates a third set of spindles. The vertical shaft communicates motion by gearing to a transverse shaft carrying cams or eccentrics at its ends. Four of these cams are for giving an alternate oscillating motion to the spindle frames, and the fifth by a ratchet and ratchet wheel communicates an intermittent motion to a roller furnished with points which draws the fabric through the machine. Each of the spindles carries at one end a brush of metallic wire, which acts upon the pile or nap of the fabric, the back of the same being supported, and the fabric pressed against the spindles by a fixed brush with springs. The fabric passes from a vessel of water over guide rollers, and between the fixed brushes and the ends of the spindles which effect the friezing, &c., of the pile. The fixing of the curl is effected by rolling the fabric round a perforated cylinder into which steam is admitted, the roller and fabric being placed in a closed vessel for about an hour. The piece is then unrolled, dried, and pressed. *Patent completed.*

2563. B. PREDAVALLE. *Improvements in producing or obtaining motive power.* Dated Nov. 15, 1858.

Here a column of fluid is caused to exert vertical pressure on a body of fluid contained in a vessel of larger base than the diameter of the column, means being provided for alternately and instantaneously cutting off and restoring such pressure, for neutralising the pressure on the side opposite to that on which motion is to be primarily produced, and for returning the vessel after having been acted upon to its original position to receive a fresh impulse. *Patent abandoned.*

2564. W. G. ARMSTRONG. *Improvements in the manufacture of ordnance.* Dated Nov. 15, 1858.

This is the specification of the celebrated "Armstrong Gun" invention. If what we have already published is not sufficient, the reader must refer to General Peel, who has sealed the specification up. *Patent completed.*

2565. M. G. DESCHAMPS and J. QUINCHE. *A new compound metal which they term "Lutetia Metal."* Dated Nov. 15, 1858.

This consists of copper from Lake Superior in America, zinc, nickel, and silver, combined in the following proportions:—Of copper, 26½ lbs. troy; zinc, 4 lbs. troy; nickel, 12 oz. 16 dwt. troy; silver, 19½ dwt. troy. Having melted the copper and nickel together, the inventor then adds the silver, and lastly the zinc: after well stirring them together, he pours the mixture in ingots. *Patent abandoned.*

2566. W. CLARK. *Improvements in colouring, preserving, and desiccating wood and marble, and in apparatus for the same.* (A communication.) Dated Nov. 15, 1858.

Here wood is first submitted to an injection of silicate of zinc in solution in water, to render it homogeneous throughout. The silicate, which is insoluble in acids, and mineral salts serves to close the pores of the wood. This operation is completed when the pressure gauge indicates, for the softest woods, a pressure of 20 atmospheres, and for the hardest woods a pressure of 60 atmospheres. The second operation consists in removing the sap of the wood, and for this purpose the patentee employs caustic lye, which permeates the juices of the wood, the application of the lyes and the washing being repeated several times. To obtain delicate colours the wood is made to undergo a bleaching process, after which operation the wood being charged with colour acquires light tints and hardiness according to the presence of different salts. To preserve woods he removes the sap as above indicated before submitting them to an injection of sulphate of copper and sulphuret of sodium, the combination resulting from the action of these two substances being insoluble in water. Wood thus prepared is not susceptible of warping or shrinking, and is readily coloured. To assist the passage of the liquids injected into the wood, he employs at one end of the timber an air pump, which also assists the dessiccation. For colouring marble he employs the same apparatus, but modifies the parts which serve to hold the wood. The marble is submitted to an injection of citric acid diluted in water in order to open the pores. After this operation the marble may be coloured, and the pores filled up with crystals, which render them much more transparent. *Patent completed.*

2567. W. CLARK. *A new mode of advertising.* (A communication.) Dated Nov. 15, 1858.

On the side of railway tickets generally left blank, it is here proposed to establish a general system of advertisements. *Patent completed.*

2568. J. G. BUNTING. *A mechanical horse-tamer or brake.* Dated November 15, 1858.

Here a post is driven into the ground, having on its upper end a stout pin; from thence diverge in a horizontal direction two poles about 30 feet long, both of which have a hole in one end to drop on to the pin in the post, the other ends being kept apart from 12 to 15 feet by cross-pieces or shafts secured in any convenient way. Upon the outer extremities of the poles are attached axle-arms to carry heavy cart-wheels. The horse being fastened within this cradle by suitable straps, &c., is unable to plunge by the weight of the wheels, to lie down on account of the under-straps, and is prevented running backward by a prop fixed to the hind pole. *Patent completed.*

2569. J BRENNAND. *Improvements in the method of effecting the locomotion of carriages, which improvements are also applicable to other similar purposes.* Dated November 16, 1858.

This consists in combining the power of steam with that of horses, &c., so that the steam may assist in the locomotion of the carriage when the resistance exceeds the animal power employed. The animal power is to be so applied that, as the resistance to the wheels is increased, by the nature of the ground or otherwise, the efforts of the horse, &c., shall open the steam-valve of an auxiliary steam-engine, and thereby impart an extra-tructive power to the driving-wheels. *Patent completed.*

2570. J. H. JOHNSON. *Improvements in machinery or apparatus for kneading dough, or working and mixing plastic materials.* (A communication.) Dated November 16, 1858.

This apparatus consists of a suitable frame fitted with a kneading-trough, having a curved or semi-circular bottom, and within which works the kneader. This kneader consists of a metal frame, fitted with a trellis, which can be removed at pleasure. The kneader fills the transverse area of the trough, and is caused to pass to and fro along the bottom and upper surface of the trough by the aid of a long slotted arm, extending upwards from the upper edge of the kneader, and working over a fixed guide-pin in a portion of the framing of the machine. Motion is imparted to this kneader by a revolving crank or eccentric, the pin of which is secured to the slot in the arm. As the crank revolves, it causes the kneader to travel along the bottom of the trough until it reaches the end thereof, when it rises to the surface, bringing with it the paste which was below, and travels back again along the surface to the opposite end of the trough again. Spur gearing and a fly-wheel are employed for imparting and regulating the motion of the machine. *Patent completed.*

2571. J. C. BOISNEAU. *An improved horse-mill or gear.* Dated November 16, 1858.

In this mill or gear the power of the horse is applied to cause the rotation of a driving-wheel or drum fitted at the end of a shaft round the wheel-work of the machine. The wheel being fixed in the shaft causes the rotation thereof, as also that of a vertical bevil-wheel, which in turn gears into and drives a horizontal bevilled pinion, formed on the crown of a large mitre-wheel, the teeth of which are inverted and drive a vertical pinion on the shaft from which the power is to be taken or applied. By proportioning the various wheels in the train to the speed required, any desired number of revolutions can be communicated to this latter shaft. *Patent completed.*

2572. A. I. H. PARENT. *An improved manufacture of buttons, and the apparatus employed therein.* Dated Nov. 16, 1858.

The patentee first forms continuous bands of strips of

Digitized by Google

metal of a suitable width by turning over the end of each strip into the form of a hook, and engaging the hook in the end of the next strip in it and then flattening the ends down. The continuous band being thus formed he takes it to a cutting and stamping machine in which he uses hollow concentric punches which are driven from eccentrics upon a shaft in such manner as at each stroke to cut a disc from the continuous band, depress the centre or body thereof into a matrix, and leave a raised edge or rim all round. By means of an eccentric upon the shaft already named one end of a lever is depressed, whereby a connecting rod is made to move a ratchet, which entering into a ratchet wheel connected with the feed rollers through which the continuous band is passed regulates the feed of the band in accordance with the stroke imparted to the punches. The same feed rollers may be used for different sized buttons by giving more or less advance to the ratchet wheel. The opposite end of the lever which is made to impart motion to the ratchet is fitted with a spring in order to raise that end of the lever depressed by the eccentric. The cupped discs produced as aforesaid have placed in them first a disc of metal which is of such size as just to fit in them. Thus prepared the partially-formed button is placed in recesses formed in an endless belt of gutta-percha or other like suitable material, and brought under first a punch which sets and fixes the blanks in movable shaped rings held in a revolving platform supported under the endless belt, while in these cups the blanks are brought between punches and matrices whereby the three surfaces are compressed, dished, and perforated with the required number of holes, and are then finally shaped between another punch and matrix, after which the buttons are pushed up into a cylinder from which they fall into any receptacle provided for them. Pins for clearing out the holes in the buttons may be fixed in this cylinder. The punches and matrices are fitted with springs. The whole of the motions in this second machine are derived from eccentrics on a shaft to which rotary motion is communicated. *Patent completed.*

2573. J. SAMUEL. *Improvements in sleepers or bearers for rails.* Dated Nov. 16, 1858.

This relates to a previous patent of the patentee dated 5th April, 1850, and consists in constructing the sleepers or bearers for the rails of railways of metal in a hollow semi-spherical, conical, semi-spheroidal, semi-ellipsoidal, or other like form, or with rectilinear sides in the form of a square or polygonol pyramid, or of a form partly rectilinear and partly curvilinear, such bearers or sleepers being provided on their upper surfaces with a trough, recess, or depression so that by blocks or wedges of wood placed at each side of the web of the rail, the rail may be held in the trough, recess, or depression clear of the bottom of the same. The sleepers or bearers may be either plain or corrugated, and are intended when laid to be packed or filled on the inside with ballast. To facilitate the packing of the sleepers or bearers they are each formed with a dovetail shaped aperture in the side thereof. *Patent completed.*

2574. S. TAYLOR. *Improvements in fountain pens.* Dated November 16, 1858.

Each pen here consists of a tube to contain the ink. This tube is at all times closed at the upper end. The lower end of the tube when supplied with ink, is closed by the introduction of a flexible elastic plug, by preference of vulcanized india-rubber. The pen is introduced between the elastic plug and the interior of the tube, so that when the writing points or nibs are pressed on in the act of writing, the plug will yield and ink will be allowed to flow to the writing points or nibs. *Patent abandoned.*

2575. C. J. C. PERRY. *An instrument to be used chiefly on board ship for approximating in certain cases the course of an approaching vessel either in the day or night, and the relative angle of both ships' courses, in order to avoid a collision; to be called Perry's Anti-collision Dial.* Dated November 16, 1858.

The great desideratum attending many cases of collision, and of vessels passing and crossing very near each other in the night time, appears to be an adequate knowledge of the direction in which each other ship is steering, or else, what is almost the same thing, the particular tack on which the approaching ship is sailing. The instrument is devised by the inventor for indicating this direction. *Patent completed.*

2576. J. B. JOHNSON and J. SHEPPARD. *Improvements in machinery or apparatus for adjusting the permanent way of railways.* Dated November 16, 1858.

This refers to ballasting the rails. This the inventors effect by apparatus upon the lever principle which consists in ramming the ballast. To an arm capable of being hooked on to the sleeper or rail they joint a lever which, being caused to turn thereon, forces the ballast forward. They employ a similar apparatus for twisting the rails into their correct position when displaced, the lower end of the lever being in this case caused to bear against the rail. *Patent abandoned.*

2577. T. KNAUTH. *Improvements in fire-arms and ordnance.* (A communication.) Dated Nov. 16, 1858.

This consists in providing the barrel of the piece with a smaller barrel fixed in it and projecting inward from the centre of the bottom or breach of the ordinary barrel, and not only opening at its exterior, and into the chamber of the piece, but at or towards its other end opening into the touch-hole or vent of the nipple so that the fire communicated through the nipple or touch-hole can enter the chamber of the piece only through the smaller barrel or tube. The smaller barrel or tube is to be so proportioned in length and diameter that the charge of powder shall lie a part of it within and a part of it around the small additional barrel, and so that the projectile or charge of shot rests upon and covers the exterior end of it, thus completely separating the powder into two parts, one being within the smaller barrel and the other outside and around it. The inner barrel is to be of a capacity to hold a quantity of powder sufficient when exploded to overcome the *vis inertiæ* of the projectile or the charge of shot, and put it in motion. It also relates to the touch-hole:—when the breech screw is in place in the main barrel, not only shall its touch-hole communicate with that of the main barrel, but the breech screw shall interrupt all communication of the touch-hole of the main barrel with the bore of the main barrel except the touch-hole of the secondary barrel. *Patent abandoned.*

2578. A. M. BERRE. *The novel application of hydrogen gas to various purposes in the arts.* Dated Nov. 16, 1858.

This consists in applying hydrogen gas in the presence of heat to various substances as a reducing agent or purifying agent while such substances are undergoing the process of distillation. *Patent abandoned.*

2579. F. A. GATTY. *Improvements in producing certain colours on cotton, linen, and silk fabrics.* Dated Nov. 17, 1858.

This consists in the use of acetic or pyroligneous acid as a means of fixing the colouring matter of madder in combination with a salt of alumina on cotton, linen, and silk fabrics for producing red and pink colours thereon by the steaming process. *Patent completed.*

2580. S. HOGA, W. P. PIGGOTT, and S. BEARDMORE. *Improvements in electric telegraphs.* Dated Nov. 17, 1858.

Here, in place of sending currents along the line wire, the patentees send the currents by the earth, and use the line wire only for the return current. *Patent completed.*

2581. M. A. MUIR and J. MCILWHAM. *Improvements in looms for weaving.* Dated Nov. 17, 1858.

This relates particularly to looms for weaving check and corded goods. The motion of the pattern-producing or figuring actions in these looms is wholly derived from a barrel or perforated figuring cylinder fitted up in connection with the drop-box for the shuttles, the take-up motion, and the heddles, so as to afford a wide range of figuring, and variable or differential action of the weaving details. *Patent completed.*

2582. C. F. VASSEROT. *A waterproof coating.* (A communication.) Dated Nov. 17, 1858.

This coating is obtained by dissolving in a water bath a certain quantity of gutta-percha with some essence of turpentine. After complete dissolution a sixth of its weight of re-in and a fifth of wax are added. The mixture should remain upon the fire while the application is made. It is applied by a brush. *Patent abandoned.*

2583. C. F. VASSEROT. *A flat clothes smoothing-iron, with moveable handles.* (A communication.) Dated Nov. 17, 1858.

This consists in forming the handles and the flat iron in separate parts. *Patent completed.*

2584. J. H. TUCK. *Improvements in the mode of laying and securing telegraphic cables, and in apparatus for the same, and for carrying on other operations under water.* Dated November 17, 1858.

This consists in forming a channel in the bed of the sea, &c., for the reception of the cable, the said channel to be covered by stones, half pipes, &c., as a protection for the cable. The apparatus consists of a carriage on which is mounted an engine (to be driven by water or air) and a set of rotary cutters driven by suitable gearing, the front bearing wheels of the carriage being also driven thereby. On the frame of the carriage there is a set of clearing tools for turning off the debris as left by the cutters. On the axle of the clearing tools are bearing wheels, to which axle is jointed the hinder part of the carriage in which is mounted a pair of wheels with broad flanges and a segmental guide through which the cable is passed, either from the surface of the water or from a drum, &c., under water, and laid in the channel as the carriage works forward. Diving bells are used in connection with the apparatus. *Patent completed.*

2585. D. W. HAYDEN. *Improvements in apparatus for heating water and other liquids.* Dated November 17, 1858.

The inventor has a boiler or reservoir of iron, &c., communicating by two pipes with a flue or grate of iron, having a hollow casing, and properly fitted with fire-bars, chimney, and door. He has in the furnace a helical coil of tubing of copper, and the ends of such tubing, open into the hollow case at points immediately opposite or nearly so, to the two pipes above mentioned. On the outside of the hollow casing which surrounds the fire grate are two taps opening into the top and bottom of the said hollow case; when water, &c., to be heated is introduced into the boiler, the tap at the bottom is closed, and the tap at the top is opened, and the liquid which is poured into the boiler passes down the lower of such two pipes into the hollow casing and coil, and the air contained in such casing escapes by the upper tap which is open. When the two pipes, the hollow case, and the coil are filled with the liquid, which will be known by its escaping by the open tap, the other is closed. The heat from the fire in the furnace is transmitted through the coil to the liquid contained therein, and also to the liquid in the hollow case which surrounds the fire grate. The heated liquid in the hollow case and coil being lighter than the colder liquid in the reservoir, descends through the lower pipe and displaces the heated liquor in the hollow case and coil, thus inducing a circulation until the whole of the liquid in the reservoir, coil, and case has attained the boiling point or other desired temperature. *Patent abandoned.*

2586. E. WELCH. *Improvements in the manufacture of tobacco, and in apparatus therefor.* Dated Nov. 17, 1858.

This consists in steaming spun tobacco and afterwards submitting it to hydraulic pressure. *Patent abandoned.*

2587. J. ROBERTSON. *Improvements in musical instruments.* Dated Nov. 17, 1858.

This relates to increasing the volume and richness of tone of musical instruments. As applied in the construction of a violin, &c., consists in working the sounding-board of increased thickness. The inner surface of the sounding-board is grooved out longitudinally in parallel lines. Similarly, the sounding boards, sounding board supports, and tracing bars of pianofortes may be grooved or channelled. *Patent completed.*

2588. M. SCOTT. *Improvements in the construction of breakwaters, parts of which are applicable in making other structures.* Dated Nov. 17, 1858.

Here a breakwater is formed by rows of piles driven so that those furthest seaward terminate at or below low water-mark, and the piles to the landward of these rise above low water-mark, until the largest piles rise considerably above high water-mark. These piles are connected by diagonal timbers, and on the tops of the piles an inclined platform is constructed, such platform being formed of transverse planking, the several planks having spaces left between them so that the water of a wave may freely pass through. *Patent completed.*

2589. E. MELLOR. *Improvements in mules and other machinery for spinning cotton and other fibrous substances, whereby the cop will be built much firmer, and prevent snarls in the yarn.* Dated Nov. 17, 1858.

This consists of a mechanical motion whereby the slide in spinning machinery (upon which the extra weight rests when the fallers are going down) is depressed or removed immediately the fallers have locked or are down in the place for winding on, so as to allow the whole weight to be brought to bear upon the lifters before the carriage begins to move inwards, and keeping the ends tight, instead of coming in, when the carriage has gone in to some extent, by sliding down the incline with slack ends. By these means the ends are stretched before the spindle begin to wind, the cop can be built much firmer and harder, and the snarls from slack ends are prevented to a very considerable extent. *Patent completed.*

2590. M. CATON. *Improvements in the treading motion of looms for weaving, and also in shuttle-boxes and wells connected therewith.* Dated Nov. 17, 1858.

This consists, 1, in placing upon the ordinary tappet shaft of the loom a plate wheel or cam having an eccentric groove in the face. In this groove works a pin or roller, which is fixed to a lever. One end of this lever works on a fulcrum, and to the other end the heddle or harness are attached or connected. The heddle may be connected to this lever in any convenient manner, so that the rising and falling of the end of the lever occasioned by the working of the pin or roller in the eccentric groove of the cam shall cause an alternate rising and falling of the heddle, one heddle rising as the other falls, and *vice versâ*, so as to produce the requisite opening or shedding of the warp threads. The second part of the invention is intended to lessen the wear and tear of the picker, and to dispense with the check strap as ordinarily employed in power looms for intercepting or lessening the force of the blow of the shuttle and picker against the end of the shuttle-box. *Patent completed.*

2591. J. BRENNAND. *An improvement in ploughs, and in other agricultural implements, and in the method of driving the same.* Dated Nov. 17, 1858.

This consists in the application of an Archimedian screw or screws, which may either be placed at each side or in front of the plough. These screws are employed for assisting the driving power, and are so arranged in connection with, and actuated by, the driving wheels of the plough as to cause the outer edges of the screw or screws to enter and "bite" the ground, and by their screwing motion to assist in drawing or propelling the plough according to the position they occupy. *Patent completed.*

2592. R. A. BROOMAN. *Improvements in apparatus for the manufacture of lace and net.* (A communication.) Dated Nov. 17, 1858.

The object here is to produce an apparatus which shall be capable of being applied to the manufacture of Brussels, Valenciennes, Mechlin, and all other descriptions of lace and of net, without any other change of form or mode of operation than that of varying the sizes of the parts according to the degrees of fineness required in the finished fabric, the said apparatus being adapted to be worked either manually or by steam or other power. The details of the invention are voluminous. *Patent completed.*

2593. S. WHEATCROFT. *Improved apparatus for uniting lace to blond and other fabrics.* Dated Nov. 17, 1858.

To connect the above-named fabrics together, so that the edge of one fabric shall lap over the edge of the other, the inventor passes these fabrics over a narrow roller, which is supplied with water by dipping into a trough containing the same. The fabrics in passing over this roller become wet on their edges, and the stiffening material with which they are dressed is thereby dissolved. The fabrics then pass between metal guides, which have a lateral adjustment to suit different widths of fabric, and after passing out from these guides they are led between one or more pairs of pressing rollers, which press the fabrics together, causing them to join with a width of lap that is determined by the adjustment of the guides. Beneath these pressing rollers, a heating box is provided, fitted with gas jets so that at the moment of pressing the fabrics together the rollers will also act as drying rollers and deliver the joined fabric fit for use. The rollers are actuated by a winch handle. *Patent abandoned.*

2594. J. PLATT and H. CHUBB. *Improvements in machinery or apparatus for making bricks or tiles.* (Partly a communication.) Dated November 17, 1858.

The patentees claim, 1, the application of india-rubber, &c., to the ram. 2. Constructing the cams or parts against which they act, or both, with pieces capable of being detached so as to be adjusted or renewed at pleasure. Also mounting the bowl or bowls or rollers upon which the cams acts for the top squeeze so as to be capable of adjustment; and lastly in the apparatus for supplying the material the use of an additional striker. The invention is not described apart from the drawings. *Patent completed.*

2595. W. CLARK. *A process of thickening, strengthening, and improving tanned hides.* (A communication.) Dated November 17, 1858.

This chiefly consists in subjecting hides to the alternate action of gelatinous and tanning liquor, by causing such liquids to filter through the hides by means of a vacuum on one side of the hide and the pressure due to a column of the liquid on the other. *Patent completed.*

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, JUNE 24, 1859.

MONEY-MAKING AT THE ROYAL MINT.

No. III.

ASSUMING that so far our explanations of the art of coining have been understood by those to whom they are addressed, some account of the operation immediately following that of the adjustment of the fillets of gold may be proceeded with. "It needs no spirit from the grave" to tell commercial men of the absolute necessity there is for gold coins to be of uniform weight. All are aware of its importance, and it is equally certain that this point is one which, if overlooked at the Mint, would lead to confusion inextricable. The adjusted strips of gold, then, are not considered "good work" unless they will yield blanks from any part of their surfaces which shall not vary in weight more than an eighth part of a grain. Rolling and drawing gold for the coinage, therefore, are highly important matters, and must be managed with extreme care. All this care, however, would be thrown away if the cutting or punching out of the blanks was not performed with much caution too. In testing the fillets, or "trying" them, as the professional term is, one cutting-punch only is employed, and it is worked by hand. This, of course, answers its purpose, and the tryer ascertains whether the character of his work is uniform by cutting a piece out here and there from the fillets passed through the drawbench, and weighing it in his trying scales. When, however, the bulk of the work has to be dealt with the case is different. From the quantity of fillets to be perforated it becomes necessary, then, to employ a number of cutting punches, and these must be of exactly equal dimensions, or all the advantages gained by former precautions would be at once sacrificed. The slightest variation ,indeed, in the diameters of these finely-turned, sharp, and well-tempered instruments would result in producing work of so irregular a nature as to predestine a very large per-centage of it to the melting pot again. It would avail little that the fillets were well adjusted if the punches, and the "beds" into which they penetrate, and through which the blank pieces fall, were not also mathematically true to each other.

There are twelve cutting-out presses at the Royal Mint, and these are very compactly placed on a circular platform of iron, in a circular room lighted from above. In the centre of this select circle revolves a heavy upright shaft driven by subterranean bevil wheels, and it supports a large fly-wheel running horizontally, and having twelve "cams" attached to its arms. Connected with each press, and passing over the heads of the workers, are horizontal rods of wrought iron. These pass also through the wall of the cutting-room. Behind that wall, in recesses made for them, are twelve vacuum pumps fitted with compound levers adjustable to the power required to be exercised in punching—and to these levers and pumps the press-rods are fastened. Supposing, now, that the mechanic has done his duty, and arranged his punches, "beds," and presses for fillet cutting, with the requisite nicety, certain boys who are to "feed" the machines with gold enter. These seat themselves on stools much resembling those of the milkmaids of "Merrie Englande," and prepare for action. Beside each boy, in a tray, is placed a batch of fillets, and now the young coiner, by placing his foot on a treadle, causes a friction roller to fall forward upon a cam of the fly-wheel; this brings up the press and with it the piston of the vacuum pump, which thus begets a forced vacuum beneath it—the piston. An instant after, the cam releases the friction roller, the atmospheric column acts on the piston—which is about 8 inches in diameter—the screw pin of the press with its punch is brought down with force, and a blank piece of gold falls into a drawer beneath. All the presses are put in motion in a similar manner, and so long as the boys keep each a foot on their treadles, and supply material for the purpose, showers of circular discs of metal—at the rate of 60 per minute, at each cutting-out press, indeed—will continue to drop into the drawers beneath. Samples are continually being taken through the day from these drawers to be tested by experienced workmen, who take care that neither wear nor tear nor accident shall interfere with the regularity of the work produced. It is not often that the twelve machines are engaged simultaneously, but from the variety of coins in use in the British dominions, it is necessary to have a sufficient number to obviate frequent changings and re-adjustments. Two hundred thousand sovereign blanks per day have, it is said, been of late obtained from the cutting-presses of the Mint, and this is perhaps the maximum rate of production of the Royal Mint itself in the shape of coin. Imagining that the whole of the fillets given out for a day's work in the cutting-room have been perforated, with the smallest possible amount of scrap, or "scissell," the latter is bound up in bundles for the melting-house, and the blanks are weighed up in bags of 720 ozs. in weight, or 2,804 in number, for the next process. Again, vigilance and excessive care are used in balancing the account of the day's duty, and careful note is taken of deficiency, if any, on the punching operations. Allowing all things to be satisfactory, the men and boys of the "drag" and cutting-rooms, of whom in all there may be fourteen, are permitted to depart, and the blanks await in the stronghold of the room their destiny. In forwarding the blanks, which at this stage very much resemble shankless brass buttons, without gilt upon them, a ticket of the weight of the contents of each individual bag is placed within it, and this the officer in charge of the next room, on receipt of the gold, examines and proves.

The weighing-room is that to which the dull-looking specimens of valuable metal are now to be removed, and this is one of the most interesting departments of the Mint. A few years back it was a lumber-room, a storehouse for tile copper, a "what-not," but at present, thanks to the energy of Captain (now Colonel) Harness, R.E., it contains some of the most beautiful machinery—on a small scale—in the kingdom. We have, indeed, had occasion to mention this noble room and its mechanical beauties before, but at the risk of a charge of repetition of information, more *must* be said about them now. It was in his desire to introduce reforms and improvements after the departure of the company of moneyers in 1851–2, that Captain Harness conceived the idea of introducing more scientific appliances for the accomplishment of the various duties of the coinage. In 1852 the first weighing machine, a copy of that which it will be remembered by some was shown at the Grand Exhibition of 1851, was placed in the Mint, and it excited the admiration of all who were unbiassed by prejudice. Naturally, some of the twenty men known in the establishment as "sizers," and whose duty it was to "size" or weigh, in small hand-balances, each of the blank pieces from the cutting-room, were averse to the introduction of these automaton weighers, which were infallible in their action. As in many other cases, however, machine labour was destined to supplant that of the hand, and in 1855 twelve automaton weighing machines were introduced, and the twenty sizing men dispensed with. It will easily be imagined that in so delicate a process as that of weighing sovereigns to the minute exactness of the 1-10th of a grain, complete freedom from irregularity of motion in the driving gear must be obtained. It is essential, too, that there should be complete freedom from vibration. In the weighing-room at the Royal Mint, these desiderata are completely effected. The machines are placed upon cast-iron stands, having four legs each, and with their surfaces planed. The feet of these stands rest upon brick-work foundations of great depth, and which serve to isolate the machines from the building, and to prevent the communication of any tremor which a movement of the weightier machinery might produce. A small atmospheric engine, placed in a corner of the apartment, gives motion to the machines. It is connected by means of a 2-inch pipe with a vacuum tube—of which we shall have to speak further bye and bye—and the air, admitted through an inverted trumpet alternately above and below a piston, acts upon the latter precisely in the same way that steam usually does. A pair of slides, governor, and fly-wheel go to make the engine resemble very much more a steam-engine. It will now be understood that there is an isolation of the power employed to work the weighing machines as well as an isolation of the machines themselves. No irregularity of motion, as regards the other mechanical contrivances, can affect the air engine of the weighing-room. It is separate and distinct from all. By means of a drum on the fly-wheel itself, and a strap, a line of bright and light wrought-iron shafting suspended by brackets from the ceiling of the lofty room, and running from end to end of it, is driven. On this shaft are placed a series of little brass pulleys — sufficient to give one for each machine—and over these pass fine gut bands to the pulleys of the machines themselves. Of course the actual power required to drive these delicate clockwork-like implements, and to feed blanks to their miniature scale-tables, is nominal. Perfect regularity of action is the only thing wanted. Well, *revenir à nos moutons*, the weighing machines are waiting, and the gold blanks are ready for distribution. A long brass spout placed at such an angle of inclination as shall cause the blanks to pass down of their own gravity, is attached to each machine, and in those spouts are now placed the golden food. At the foot of each spout, and immediately behind the scale table, a thin steel semicircular slide is made to advance and recede. Every time it advances now, it pushes forward a blank to the tiny scale; there it, the blank, rests for the space of three seconds, and the machine actually appears, at this crisis, to be endowed with the faculty of thought. It seems, like a solemn judge, to be taking into consideration all the facts in regard to a prisoner, and to be hesitating whether to acquit or condemn. Three seconds only are allowed for this trial, and the slider advancing with another prisoner very quietly pushes the first over a precipice, in order to make room for its successor. The three seconds have been sufficient for the ends of justice, however, and the fallen piece, if of the proper weight—that is, within 1-10th of a grain of the standard weight of a sovereign — will inevitably be found in the right, not the wrong, box, to which a flattened brass tube will have conducted it. Piece after piece is thus submitted to the infallible automatons, and approved or condemned on their own merits or defects. These quiet judges become eloquent at the close of the day. They tell then distinctly whether all previous operations, as rolling, drawing, and cutting, have been properly performed. If they *have*, 98 or 99 pieces of every 100 will have passed into the "medium" compartments of the machines. If they *have not*, the "light," and "heavy" boxes will contain evidence of the fact by being burdened with rejected or condemned work, destined for the crucible once more.

All silver pieces, down to the size of the sixpence, as well as all gold of whatever size, are tried by the weighing-room judges; and it may be stated that under judicious arrangements made at the instance of Dr. Graham, and carried out by certain officers in his confidence, the per-centage of good work has been wonderfully increased of late. Two and a-half years ago 70 or 80 per cent. of accepted blanks was considered all that could be obtained, *now* 98 and 99 are the usual things.

With respect to the conduct of business in this particular department of the Mint, it may be permitted us as part of the public, to say that we think it would be better—Heaven shield us from presumption in saying so!—it would be better if the weighing of piece by piece were the final instead of an intermediate operation. Other processes follow this weighing or sizeing—*for* instance, the pieces are *baked* and *pickled!* as we

Digitized by Google

shall bye-and-bye see, and may therefore undergo changes which alter their weight *after* the righteous judges have pronounced them good. In our humble opinion, therefore, the weighing of single pieces should follow, not precede the baking and pickling operations. Stamping may not interfere with them in the way described, but the action of fire and acids *must*.

It has been intimated that small silver blanks, as those for groats—now obsolete—or threepences, are not passed through the automaton hands. It is not necessary, indeed, that they should be. The are merely "ounced"—that is, they are weighed in parcels of one ounce troy, and if each ounce is found to contain the proper number of pieces, that is all that can be required. Copper, less important still, is "*pounded*," that is, care is taken that each pound avoirdupoise shall contain the just number of blanks; individual variations may exist, but on the whole pound there must be a balance of differences, or the work is bad.

We are not certain that full justice has been done to the fitments of this council-chamber of the Mint; to be fully appreciated they *must* be seen. Of course great care is taken to preserve the weighing machines—which cost £220 each, and are not larger than west-end drawing-room clocks—from damp, and rust, and dust; they are covered by glass cases, and must not be breathed upon. There are in addition to the twelve balances certain hand-test scales, which the officer of the room assures visitors will weigh accurately to the thousandth part of a grain—a microscopic quantity which he perhaps comprehends the bulk of, but with which we had rather not deal.

Assuming that the magic balances have accomplished their task with respect to the batch of golden blanks, of which in imagination our readers have not lost sight—that the defective are consigned to the "burning fiery furnace," and the goods ticketed for the succeeding operation, we follow on to the "marking-room."

PROGRESS OF ELECTRO-TELEGRAPHY.

DURING the past week the details of the successful completion of the line from Suez to Aden have been received. On the 9th of May the laying of the first part of the cable was commenced, and finished on the 11th from Suez to Cosseir, the first intermediate station of the Red Sea Telegraph Company, where a relay will be fixed. The depth in this length does not exceed 350 fathoms in any part. Between Cosseir and Suakin, the next stage, which occupied four days in laying, the greatest depth was about 450 fathoms; from Suakin to Aden, a distance of about 630 nautical miles, the cable was laid without any intermediate station, but it was brought so near to the island of Perim that a station can readily be established there if necessary. The depth in this length does not exceed 250 fathoms, and the bottom is soft, so that the difficulties of cable-laying in the Red Sea have been the subject of a good deal of romancing.

The announcement of a proposed British Transatlantic Telegraph Company, as a rival to the old Atlantic Company in seeking funds from the public, has not been made in such a way as to claim our support, even if the present company had not earned the goodwill and sympathy of all unprejudiced observers by its courageous and persevering endeavours to accomplish the greatest feat of the age in which we live. The uncalled-for abuse of those who have led what was looked on by many as a forlorn hope, and have succeeded in mounting the breech even though the vantage ground could not be maintained, is a poor recommendation to our favour, and it is not difficult to distinguish in the *animus* which has been exhibited in the notices to which we refer, that jealousy and ill-feeling which we have before had occasion to censure on the part of the former electrician of the company, who was so fortunate as to escape the discomfits and risks shared in by those who were actually concerned in laying the Atlantic cable. Nor could such a spirit be shown with more bad taste than by one whose lack of practical knowledge was the greatest misfortune of his former employers; and whose neglect of, or unfitness for, his duties has been the cause of the present position of the Atlantic Company. An examination of the persons under whose names the new company is registered does not encourage us to look for much demand for the stock among capitalists or commercial men, nor are the names likely to obtain the regard of the public. One of them, we regret to see, is a young gentleman who was permitted by the Atlantic Company to go with the expedition as a reporter to the press, and who has now put down his name for a hundred shares in the projected company.

The gutta-percha and copper for the new cable to Gibraltar and Malta have been ordered by Government from the Gutta-percha Company; it is altogether half-an-inch in diameter, the copper being a strand weighing 400 lbs. to the mile.

Messrs. Glass and Elliott have nearly completed the new cable of three wires to be laid for the Submarine Telegraph Company from the coast of Norfolk to Heligoland, to join the length already laid thence to Tonning, and have also made great progress with the cable of six wires to be laid from Folkestone to Boulonge for the same company, in order to assist the south continental traffic, which has increased very much since the Dover and Calais cable, the first submarine line ever laid, was carried out in 1851 by the Submarine Company. A single-wire cable is also being made at the same works at Greenwich for the Isle of Man, and a two-wire cable for the line of the Mersey Board between Liverpool and Holyhead, to replace the old line of semaphore telegraph which has been allowed to exist up to the present time, to the disgrace of the Dock Committee, in whose hands the matter has been.

The British and Irish Magnetic Telegraph Company have nearly finished their additional wires to the north to accommodate the north of Europe traffic by the Hanoverian and Danish lines.

SEWING MACHINES.

THE following statistics regarding the sewing-machine trade in Great Britain and the United States (compiled from patent-office reports, from the *Scientific American*, and from the reports of persons intimately acquainted with the manufacturers and users of machines in both countries) are probably as near an approximation to the facts as can be obtained:—

	Great Britain.	United States.
No. of Patents granted ...	200	300
Manufacturers	5	25
Varieties of machines	6	30
" " Lock-stitch Machines	3	10
Machines sold weekly	100	1,500
Prices	£3 to £30	£1 to £30
Lowest price for a lock-stitch machine	£11	£10
Whole number in use	10,000	100,000

A considerable number of machines have been imported from the United States into England, but the parties using them do not wish the fact to be made public, lest they should be sued for an infringement of the patent dated December 1, 1846, granted to W. Thomas, of London. This patent extends only to England—hence a large number of American-made machines are used in Scotland and Ireland. In England, only one kind of lock-stitch machine is manufactured, and its lowest price is £22. In Scotland or Ireland a lock-stitch machine may be bought or imported from the United States for £11.

These are facts certainly far from gratifying to our national pride. Although the invention of the lock-stitch sewing machine was made in England by Fisher and Gibbons, the original patentees of the sewing machine, *two years before* it was patented in America by Elias Howe, jun., yet now there are ten times more machines used in the United States than in Great Britain. Why, then, has the progress of the sewing machine been so slow in this country? Chiefly for two reasons:—1st, There has been no competition among manufacturers; and, 2ndly, prices are far higher in England than in America. In the United States as good a machine can be bought for £10 as is sold in England for £22. Competition among manufacturers has improved, cheapened, and advertised American machines. And if the trade had been conducted in this country as it has been in the United States—if the public had been permitted to select from the best machines that could have been brought into the market—and if these machines had been offered for sale at a reasonable price, this trade would now be giving employment to 100,000 mechanics and operatives who are at present engaged in less lucrative employments, and for the past two or three years Great Britain would have been a gainer to the amount of, at the very lowest estimate, three million pounds annually.

MR. HENRY BESSEMER
ON THE MANUFACTURE OF MALLEABLE IRON AND STEEL.

(*Concluded from p.* 398.)

THE casting of large masses of a perfectly homogeneous malleable metal into any desired form, rendered unnecessary the tedious, expensive, and uncertain operation of welding, now employed wherever large masses were required. The extreme toughness and extensibility of the Bessemer iron was proved by the bending of cold bars of iron 3 inches square, under the hammer, into a close fold, without the smallest perceptible rupture of the metal at any part; the bar being extended on the outside of the bend from 12 inches to 16¼ inches, and being compressed, on the inside from 12 inches to 7½ inches, making a difference in length of 9¼ inches between what, before bending, were the two parallel sides of a bar 3 inches square. An iron cable, consisting of four strands of round iron 1½-inch diameter, was so closely twisted while cold as to cause the strands at the point of contact to be permanently imbedded into each other. Each of these strands had elongated 12½ inches in a length of 4 feet, and had diminished 1-10th of an inch in diameter throughout their whole length. There were also exhibited some steel bars 2 inches square and 2 feet 6 inches in length, twisted cold into a spiral, the angles of which were about 45 degrees; and some round steel bars 2 inches in diameter bent cold under the hammer into the form of an ordinary horse-shoe magnet, the outside of the bend measuring 5 inches more than the inside.

The steel and iron boiler plates left without shearing, and with their ends bent over cold, also afforded ample evidence of the extreme tenacity and toughness of the metal; while the clear, even surface of the railway axle and piece of malleable iron ordnance were examples of the perfect freedom from cracks, flaws, or hard veins, which formed so distinguishing a characteristic of the new metal. The tensile strength of this metal was not less remarkable, as the several samples of steel tested in the proving machine at Woolwich Arsenal bore, according to the reports of Colonel Eardley Wilmot, R.A., a strain varying from 150,000 lbs. to 162,900 lbs. on the square inch, and four samples of iron boiler plate from 68,314 lbs. to 73,100 lbs.; while according to the published experiments of Mr. W. Fairbain, Staffordshire plates bore a mean strain of 45,000 lbs., and Low Moor and Bowling plates a mean of 57,120 lbs. per square inch.

There was also another fact of great importance, in a commercial point of view. In the manufacture of plates for boilers and for ship-building, the cost of production increased considerably with the increase of weight in the plate; for instance, the Low Moor Iron Company demanded £22 per ton for plates weighing 2½ cwt. each, but if the weight exceeded 5 cwt., then the price rose from £22 to £37 per ton. Now with cast ingots, such as the one exhibited, and from which the sample plates were made, it was less troublesome, less expensive, and less wasteful of material, to make plates weighing from 10 to 20 cwt., than to produce smaller ones, and, indeed, there could be but little doubt that large plates would eventually be made in preference, and that those who wanted

Digitized by Google

small plates would have to cut them from the large ones. A moment's reflection would, therefore, show the great economy of the new process in this respect, and when it was remembered that every riveted joint in a plate reduced the ultimate strength of each 100 lbs. to 70 lbs., the great value of long plates for girders and for shipbuilding would be fully appreciated.

At a time when the manufacture of ordnance occupied so large a share of public attention, it was interesting briefly to point out the great facility which the Bessemer process afforded of forming masses, both of malleable iron and of steel, of a size suitable for the heaviest ordnance, without any welding together of separate slabs, or the more costly mode of building up the gun with pieces accurately turned and fitted together. Many attempts had been made to produce wrought-iron ordnance, and this object had been successfully accomplished in the case of the large gun produced at the Mersey forge. But, however perfect this one gun might be, the time required to make it, and its immense cost, manifestly rendered it still a great desideratum to produce guns rapidly and cheaply, of a material equal to, or greater in tensile strength than wrought-iron, and if possible free from the liability which that material had to flaws and to deterioration during its long exposure to a welding heat. It was believed that the Bessemer process supplied this desideratum, as masses of cast malleable metal could be produced of 10 or 20 tons in weight in a single piece, and two or three such pieces might be conveniently made by the same apparatus in one day. The metal so made might be either soft malleable iron or soft steel. In order to prove the extreme toughness of such iron, and the strain to which it might be subjected without bursting, several cast and hammered cylinders were placed cold under the steam hammer and were crushed down without the least tearing of the metal, as was shown by the samples exhibited. These cylinders were drawn from a round cast-iron ingot of only two inches greater diameter than the finished cylinder, and in the precise way in which a gun would be treated; they might therefore be considered as short sections of an ordinary 9-pounder field-piece. The tensile strength of the samples, as tested at the Royal Arsenal, was 64,566lbs. per square inch, while the tensile strength of pieces cut from the Mersey gun gave a mean of 50,624lbs. longitudinally, and 43,339lbs. across the grain; thus showing a mean of 17,550lbs. per square inch in favour of the Bessemer iron.

If it was desired to produce ordnance by merely casting the metal the ordinary founding process might be employed, with the simple difference, that the iron instead of running direct from the melting furnace into the mould must first be run into the converting vessel, where in ten minutes it would become steel, or malleable iron, as was desired, and the casting might then take place in the ordinary manner. The small piece of ordnance exhibited served to illustrate this important manufacture; and it was interesting in consequence of its being the first gun that was ever made in malleable iron, without a weld or joint. The importance of this fact would be enhanced when it was known that conical masses of this pure tough metal, of from five to ten tons in weight, could be produced at Woolwich at a cost not exceeding £6 12s. per ton, inclusive of the cost of pig-iron, carriage, remelting, waste in the process, labour, and engine power. The conical ingots being cast in iron moulds, the great delay in moulding in loam would be avoided; and as the iron moulds employed might be removed from the casting pit within an hour after the metal had been poured into them the tedious interval of three days, now required by the cast-iron guns before removal, would be also avoided, thus immensely increasing the capabilities of the foundry. If it was assumed that these advantages were about equal to the cost of hammering the cast ingot, then, by this process, it would be practicable to produce guns of any size in hammered cast steel, or malleable iron, ready for the boring mill, at about the same cost as the cast-iron guns now in use; but if the weight of the guns could be reduced by 20 or 25 per cent., in consequence of their superior strength, then an actual saving in that proportion would be effected in the first cost of every gun so made. These important facts had been laid before the Government, and their advantages were stated to be fully appreciated by Colonel Eardley Wilmot, the superintendent of the Royal Gun Factories, who had evinced a great interest in the progress of the invention from its earliest date, and to whose kindness the author was indebted for the many valuable trials of the tensile strength of the various samples of metal that had been submitted for investigation.

It would be interesting to those who were watching the advancement of the new process, to know that it was already rapidly extending itself over Europe. The firm of Daniel Elfstrand and Co., of Edsken, who were the pioneers in Sweden, had now made several hundred tons of excellent steel by the Bessemer process. Another large manufactory had since been started in their immediate neighbourhood, and three other companies were also making arrangements to use the process. The authorities in Sweden had fully investigated the whole process, and had pronounced in favour of it. The large steel circular saw plate exhibited was made by Mr. Göranson, of Geffle, in Sweden, the ingot being cast direct from the fluid metal, within fifteen minutes of its leaving the blast furnace. In France, the process had been for some time carried on by the old established firm of James Jackson and Son, at their steel works, near Bordeaux. This firm was about to manufacture puddled steel on a large scale. They had already got a puddling furnace erected and in active operation, when their attention was directed to the Bessemer process, the apparatus for which was put upat their works last year; andthey were now extending their field of operations by putting up more powerful apparatus at the blast furnaces in the Landes. There were also four other blast furnaces in the south of France in course of erection, for the express purpose of carrying out the new process.

The irons of Algeria and Saxony had produced steel of the highest quality.

Belgium was not much behind her neighbours; the process was now being carried into operation at Liège, where excellent steel had been made from the native coke iron; while in Sardinia, preparations were also being made for working the system. Russia had sent to London an engineer and a professor of chemistry to report on the process; and Professor Müller of Vienna, and M. Dumas and others from Paris, had visited Sweden, to inspect and report on the working of the new system in that country.

The Bessemer process might therefore be now fairly considered an accomplished commercial fact; and in a country like England, where the manufacture of iron and steel formed so important a branch of the national industry, and was so necessary an element in all the great manufacturing operations, it must be admitted that an impartial examination of the new system was of the highest importance, not only to those immediately concerned in the production of malleable iron and steel, but to the country generally.

That the process admitted of further improvement, and of a vast extension beyond its present limits, the author had no doubt; but those steps in advance would, he imagined, result chiefly from the experience gained in the daily commercial working of the process, and would most probably be the contributions of the many practical men who might be engaged in carrying on the manufacture of iron and steel by this system. Hitherto the process had been brought into its present practical and commercial state without recourse to any of the numerous inventions which were supposed by the several authors to be essential to the success of the system; but any real improvement that might be brought forward would be cordially received and encouraged.

Parliamentary Proceedings.

HOUSE OF COMMONS.

JUNE 21.

THE SHIPBUILDING DEPARTMENT OF THE NAVY.

Mr. JACKSON asked the noble lord, the Secretary to the Admiralty, whether he intended to proceed with the motion for the appointment of a select committee to inquire into the management and expenditure of the shipbuilding department of the navy, notice of which stood on the paper in his name.

Lord C. PAGET was sure that his hon. friend would give him credit for an earnest desire that there should be an inquiry into the matters connected with the shipbuilding department of the Admiralty, and he was quite certain that the noble duke who now presided over the Admiralty had it equally at heart that this great branch of our naval service should be thoroughly looked into. If he now asked permission to withdraw the motion of which he had given notice it was not that he had at all desired to shirk the question, but that he thought that his hon. friend and those who, like him, were anxious for this inquiry should put some faith in the good intentions of the noble duke and in his own. He only asked them not to spur a willing horse, and under these circumstances he should not proceed with the motion which stood in his name.

Mr. JACKSON gave notice that in the next session of Parliament he should move for a select committee to inquire, not only into the shipbuilding department, but also into the general expenditure of the navy.

THE WAR DEPARTMENT.

Colonel DUNNE gave notice that on an early day he should move the appointment of a select committee to inquire into the organization of the civil portion of the war department, its expenditure, and the various branches into which it was divided.

VOLUNTEER RIFLE CORPS.

Mr. PALK gave notice that as Her Majesty had decided to promote the formation of volunteer rifle corps, as well as artillery corps in maritime towns, he should on Tuesday next move that the House should resolve itself into a committee to consider an address praying that she would give directions that the necessary arms, accoutrements, and ammunition should be furnished to them, and assuring her that the House would make good the same.

OUR NAVAL DEFENCES.

Sir C. NAPIER, in announcing his intention to postpone the motion for a select committee to inquire into the state of the Admiralty of which he had given notice, said that he had been made very uneasy by a statement which he had heard had that forenoon been made by Lord Derby. He had heard that Lord Derby had that morning, at a meeting of his friends, stated that he understood from Mr. Gladstone, the new Chancellor of the Exchequer, that he was quite shocked at our expenses, and that he was determined to reduce them. France had a fleet nearly as large as ours, and Russia had one much larger. With regard to Russia, he had read the following important statement in the *Times* of Saturday:—

"The shipments of machinery to Russia since the opening of the navigation are stated to have been on a scale which will go far to account for the necessity that has existed for the transmission of gold from St. Petersburg to London, especially as similar orders have been executed in America and elsewhere, many of which are paid for by draughts on this country. Within the last month the Hercules steamer has landed from St. Petersburg five complete sets of engines for first-rate men of war, and many of our engineering firms have still large commissions to execute. According to the last dates the utmost exertions were being made in all the naval departments, in preparation, it was said, for the return of the Grand Duke Constantine. The Neva division of the Russian fleet is now asserted to comprise 80 first-class gunboats, constructed on the best recent models, while the Baltic fleet consists of 35 sail of the line, 14 of which, at present at Cronstadt, are screw line-of-battle ships of from 80 to 120 guns each. It is affirmed that during the last month a continental contract has been in execution in this country for 60,000 bags of ships' bread. This would suffice for 30 sail of the line for six months. Looking, also, at the purchases of horses, coal, and other material, the flow of money to England, which has been one of the first consequences of the war, is easily explained."

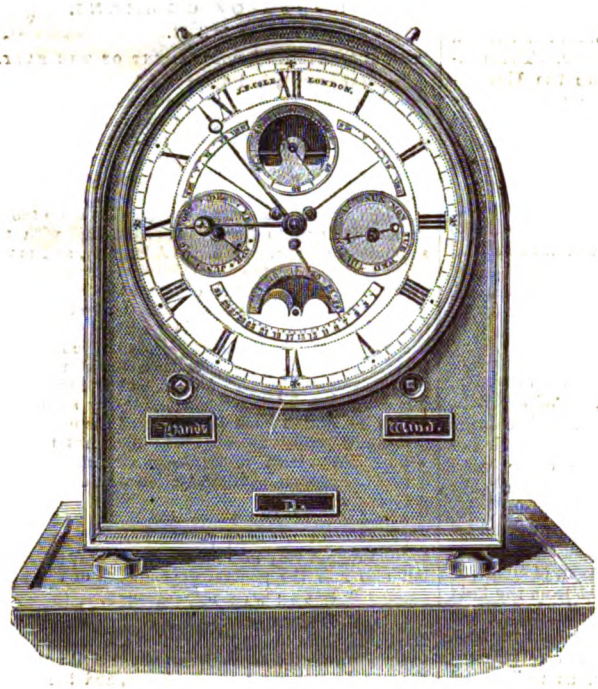
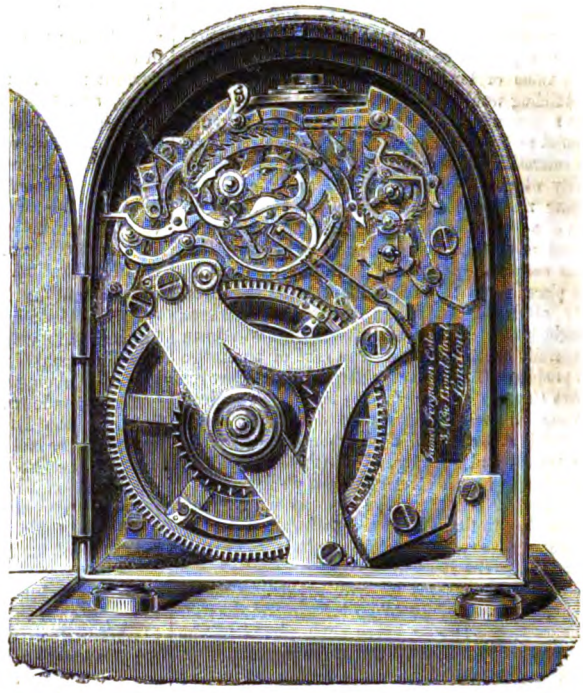
COLE'S PORTABLE ASTRONOMICAL CLOCK.





COLE'S PORTABLE ASTRONOMICAL CLOCK.

THE following description of a portable astronomical clock, designed and made by Mr. J. F. Cole, whose eminent ability as a practical horologist we some time since mentioned, is taken from the *Journal* of the Horological Institute :—

"The two engravings represent a front and back view of the clock, on a scale of proportion equal to half the dimensions of the original, which is contained in a silver case about six inches in height. The general design or calibre of the movement of this clock is an arrangement so disposed as to admit the largest amount of power in the smallest space, as shown by the unusually large diameter of the great wheels and double-acting barrel which drives the two trains of the going and striking parts, giving hours and quarters regularly on bell springs, by mechanism resembling in some particulars clocks of the justly celebrated M. Breguet. This clock also repeats the hours and quarters at pleasure, by touching a projectile stop at the top of the case. The dial plate, also of silver, is quite an original design as regards arrangement of the various indications on the several circles and scales of figures on segments drawn from three eccentric points surrounding the true centre of the hour circle. Hours, minutes, and seconds are shown by the principal steel hands, and the time is governed by a compensation balance and spring as usual; the escapement being a detached lever, with a flat steel wheel having the impulse angles formed wholly on the wheel teeth, in the manner of Graham's horizontal wheel, without columns; the pallets acted on by the planes of the teeth being two arms of equal length, with ruby pallets set to represent the edges of a ruby cylinder scaping over three teeth. The wheel in this is a tempered one, and has performed well for 30 years, without the slightest injury from action. On the dial plate, the small circle at the right shows the days of the week; the corresponding circle at the left shows the months; and the segment below shows the days of the month by a gold indicator hand, which is governed by the mechanism seen at the right of the back view given in the engraving. This particular mode of showing the perpetual day of the month is an original improvement, constructed to correct the unequal months of 30 and 31 days, for the 28th day of February, and the 29th day in leap year. Below the centre is a semicircular indication of the moon's age and phases; and above the centre is a similar aperture enclosed by the second's circle. Within the circle is a blued steel plate, carrying a disc of silver representing the apparant motion of the sun. This small disc will appear above and disappear below the moveable horizon daily, through all seasons of the year; the smaller segments at the left and right with gold indicator hands show the time of sun rising and setting.

"Outside the circular rim of the dial are two apertures—one where the key is inserted for winding the clock, and the other for setting the hands as marked on the gold tablets. The key applied at this one point commands all the motions, which are always correct, unless the clock is allowed to go down. On the side of the silver case is a sliding stop, which may be set to strike hours and quarters, or quarters only with the hour at the proper time; and if the stop is set to the lowest point, at the mark "silent," the power of the striking part is transferred to the going part, and by this the period of going will be prolonged to nearly a month. The editor of the journal before named states that seven similar clocks and pocket watches containing the above and other properties were constructed and made by Mr. Cole, about 30 years since, at prices varying from 100 to 300 guineas each."

It may be interesting, in connection with this subject, to state that we have before us a letter written by the Rev. W. B. Hawkins, M.A., F.R.S., in which reference is made to other improvements made by Mr. Cole in horological instruments. The writer mentions in particular a small carriage clock, and a small lever watch, which are particularly remarkable. "The carriage clock, which is of small size, strikes," he says, "the hours and quarters, and repeats them as well, and indicates on the dial the rising and setting of the sun, the phases of the moon, the perpetual day of the month of the year. It performs all these actions with much accuracy, and altogether displays singular talent and skill in its design and execution. The dial is an excellent example of combination and arrangement—a matter of no little difficulty where so much is required to be placed in a very small space. The lever watch is without a regulator, and although seven years have elapsed since it was last cleaned it still maintains a rate, in point of steadiness and accuracy, quite chronometrical."

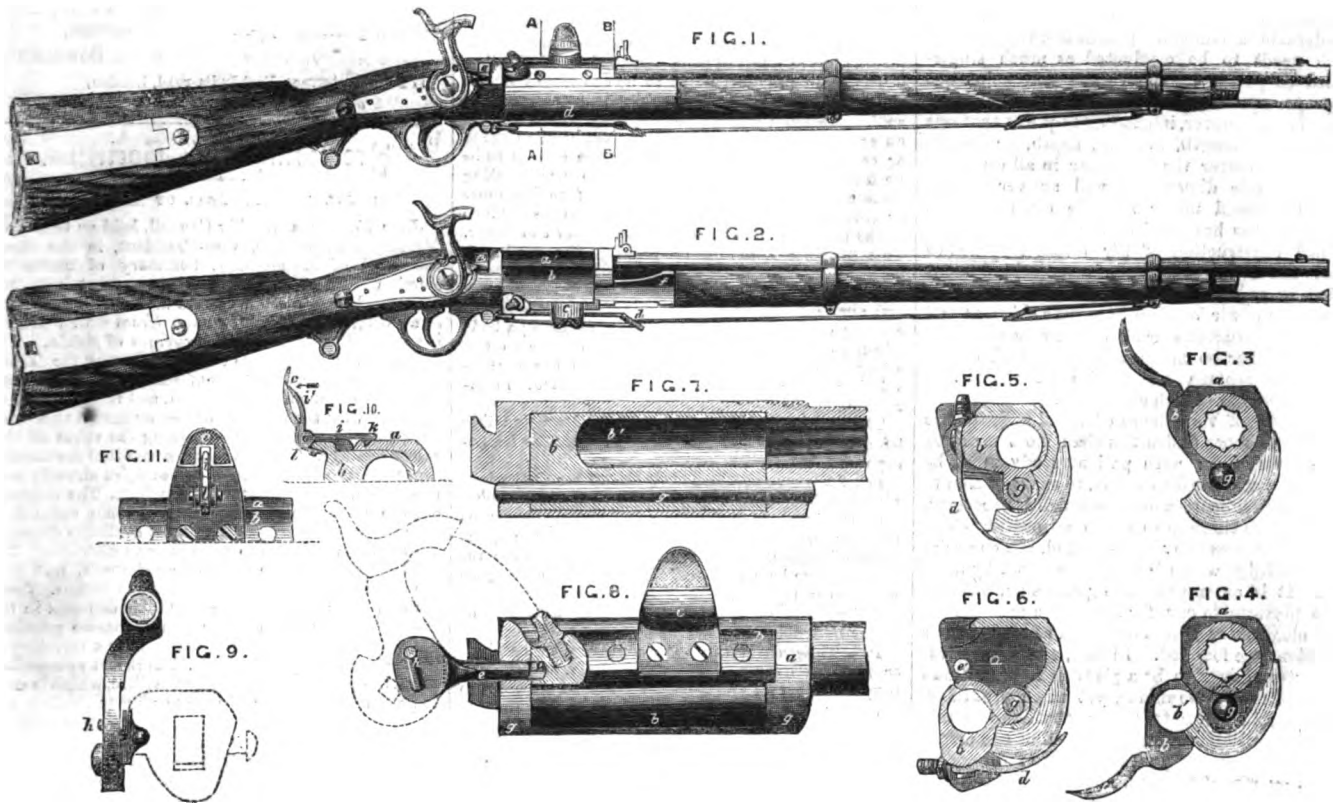
LEETCH'S BREECH-LOADING RIFLED SMALL ARMS.

THE rifled fire-arms already adopted in our services, although superior to those of any other nation, are certainly not so perfect as the scientific resources of English mechanics can make them. The breech-loading principle must prevail before the wonderful precision, the enormous range, and the fearfully-destructive powers of the rifle are fully developed. We therefore continue to place before our readers the best information which can be obtained on rifled ordnance and small arms. This week we illustrate Leetch's breech loader. This arm takes either the regulation ammunition, any special form of cartridge, or even loose powder and ball, and has a range and penetration equal if not superior to the Enfield rifle.

By the accompanying engravings the detailed arrangements will be more clearly understood. Fig. 1 represents the side elevation of a military rifle. The breech is here represented as closed, and the hammer on full cock ready for the discharge of the rifle. *d* is a guard plate of metal, applied merely for the purpose of covering the hinge of the breech; *c*, a thumb piece projecting from the upper side of the breech *b*, in order to obtain a leverage for the purpose of opening and closing the breech. *e* is the locking bolt. Fig. 2 represents the same rifle with the breech opened to receive a fresh charge. *a'* is the opening left in the barrel through which the breech *b* opens and closes; *f*, a portion of the gun-stock hollowed out to admit of the cartridge or charge being introduced into the breech chamber. Fig. 3, a cross section at *B B*, Fig. 1, with the breech closed. Here the hinging of the breech to the barrel is more clearly seen. *g* is the hinge pin. Fig. 4 shows the same section, but with the breech *b* opened, the open end of the breech chamber, *b'*, being presented to view The Figures 3 and 4 are sections in front of the breech. Figs. 5 and 6 are similar sections, but taken at *A A*, and cutting through the breech. In Fig. 6, *e'* represents the hole in the butt end of the barrel *a*, through which the locking bolt is projected. Fig. 7 is a horizontal section through the centre of the breech when closed into the barrel, the letters of reference referring to the same parts as in all the other figures. Fig. 8, is a horizontal section through that portion of the butt end of the barrel and of the breech in which

Digitized by Google

LEETCH'S BREECH-LOADING RIFLED SMALL ARMS.



the locking bolt *e* acts. The position of the hammer on full cock is here represented by dotted lines in order that the form of the locking bolt may be seen. The hole *e'* shows the extent of the traverse of the locking bolt during the fall of the hammer. *h* is a pin which secures the bolt to the hammer; it works in a slotted hole cut in the flattened end of the bolt *e*, to allow of the horizontal movement of the bolt during the curved travel of the pin when the hammer falls. Fig. 9 shows an edge or front view of the hammer, with the locking bolt *e* attached to it by the pin *h*. By the foregoing description it will be clearly seen that it is impossible for the gun to be accidentally discharged when the breech is imperfectly closed, or, in other words, when the chamber of the breech is not in line with the bore of the barrel, because in that case the locking bolt *e* would not be in line with the hole *e'* in the breech.

When this gun is discharged, the force of the gases evolved by the explosion of the gunpowder is sustained by the solid chamber hinged to the barrel, by which means the same strength for resistance is obtained as in the ordinary gun, while the difficulties arising from the ramming down, injury to the bore, irregularities on the surface of the bullet incidental to carriage, or faulty make of the ammunition, are avoided. The gun will not receive any charge or projectile which it is incapable of discharging. We consider these points well worth the consideration of the War Office before they again lay out large sums of money on useless foreign inventions for which no suitable military ammunition can be found. "The fine theories and assumed facts" laid down by the constituted authorities have had, in more than one instance, to give way before the practical common sense of our mechanics. When arms were actually wanted the English contractors were the only ones who produced them in time for positive use. This should be remembered now that immense orders are offered for contract.

The War Department ought again to give their serious attention to this subject of small arms. The Enfield rifle is an expensive weapon, and its use in India has proved that it is not quite up to the mark. But if they give practical men like Mr. Leetch (who rifled the first guns used in the Crimea, and whose carbine has been approved by two Cavalry Boards, in 1856-57, and two Commanders-in-Chief,) no encouragement or suitable remuneration for actual outlay, the authorities at Pall Mall cannot expect the assistance of the well-proved talent of such men. Now that the Volunteer Gentlemen of England are taking to the rifle it will soon arrive, we trust, at the same perfection as has been obtained in all articles used in our national sports.

CAPTAIN FISHBOURNE ON NAVAL ARCHITECTURE.*

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—By your published account of a lecture which was recently delivered at the United Service Institution by Captain Fishbourne, R.N., it appears that much has been said which is likely to cause many persons to believe that the science of naval architecture is imperfectly understood; and, if understood, that it is but little used by those who have constructed ships for the Royal Navy. The lecturer says:—"If the science of naval architecture is to be progressive—if, in fact, we are to elevate it to the rank of a science, which it is now only in part, whatever professional men may say to the contrary," &c. In making this bold assertion, it would have been well to have defined the rank of science. If, without a plan to copy from, a man constructing a ship to answer any possible and reasonable qualifications demanded, without a blunder, thereby entitles himself to the rank of a scientific man, most certainly the science exists. The lecturer also states that we condemned a fleet of ships, and does his best to make his hearers believe that the present fleet should be condemned, principally because they are wide in proportion to their draught of water; and that, in building such ships, we were steering vastly wide of the track which science dictated. Now, the simple fact is, these ships could not have been built less wide to have been so serviceable as they are; and no standard treatise, truth, or science dictated anything else. The ships of the experimental squadron of 1846 and 1847 most certainly sailed well, though some of them rolled a great deal. If the naval architects who constructed them had been the owners of so fine a fleet, they would not have been wise to have allowed the rolling ones to have enjoyed such a privilege on their next cruise. Naval architects do not assume that other persons cannot understand the science; they know but too well that it is easy to explain any part of it to an intelligent mind if they choose, although no one would be wise who did so without being paid the estimated price or market value of such knowledge.

The remarks in the lecture about the qualifications of differently-formed floating bodies must appear absurd to either the scientific or the practical man; neither can believe that a flat body will roll more than a round one. It is a notorious fact, among shipbuilders and naval architects, that, if any one will so study his profession as to be able to define what is required to enable a war-ship to do any possible duty, he will be able to obtain his wish by letting the architect alone in constructing the article which is wanted. I do not wish it to be understood that every one who claims to be a naval architect should be considered as such, for many assume the name who do not understand the elementary laws which govern that or any other science.* The remarks against building ships of great height out of the water will not alter the fact, that such ships have a great advantage over a low-built enemy either at a distance or at close quarters. It seems to be far more easy to censure the deeds of professional men than to point out the way to alter the present ships to make them more serviceable, or to construct ships in future to make them perfect. The elementary laws which govern a floating body under various circumstances have been well investigated and fully

* The above letter was received before the leading article which appeared in our last number was published.

* Naval architects certainly need improving. Perhaps some may be taught a little of the art of gunnery by Captain Fishbourne's description of the qualifications of smooth-bore and rifle guns. Since rifle guns have had an elongated shot to throw they have shamefully beaten our old friends the smooth-bore guns, which are not allowed such a privilege.

Digitized by Google

defined by many scientific men in a clear and simple manner. The student, to make himself proficient, must accompany his studies with a considerable amount of practical investigation, which needs to be conducted as much single-handed as possible. The results will point out the proper course to be pursued in constructing a ship. It is, however, impossible to prove that one proportionate length, breadth, depth, or height will answer better than another in all cases, for any reasonable dimensions will answer if the vessel be placed under suitable circumstances. Much that has been said by the multitude about the bad construction of Sir William Symond's ships is not true; yet a want of practical judgment existed in regard to the use made of some of them. All of Sir William Symond's ships, as well as those constructed since his time, which Captain Fishbourne has so much to complain of, can be made what seamen call good sea-boats, if it is required, without much alteration.

The study of the science of naval architecture is subject to more difficulties than most men are willing to endure: with patient study must be combined a resolute disposition, to enable a man to obtain the practical knowledge which is necessary. Those who go through so rough an ordeal, which they usually must do single-handed, are choice of that knowledge which is sought so much by amateurs. It is an unprofitable profession, but still it is a pleasurable one, for it makes a man master of the elementary truths on which so many other professions are founded. In fact, as soon as naval architecture ceases to be a pleasure to him, a man mostly takes to some minor, yet more profitable, profession, in order to obtain that respectable position in society so much required as age creeps on, and the energy of youth begins to fail.

The remarks of Sir Wm. Armstrong at the conclusion of Captain Fishbourne's lecture, are such as were to be expected from a man of science and practical judgment. His description of his experience in the qualifications of projectiles no one can complain of. His remarks about the number of guns a ship should have do not affect the character of naval architects, whose business it is to construct ships to carry either a few or great number, as it may be demanded by those who use them; he appears to have been too wise to condemn the knowledge or ability of professional men, whose business he does not understand.

I am, Gentlemen, yours, &c.,

GEORGE SOLE, Jun.

North Shields, June 15, 1859.

SUBMARINE TELEGRAPHS.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE"

GENTLEMEN,—As everything relating to submarine Telegraphs possesses at this moment a public interest, I venture to send you a few facts on this important subject.

Assuming a cable to be safely submerged to a depth of three miles, and its electrical condition not impaired, we must now consider what mechanical effect such a pressure of water produces on the insulator. From practical tests I have made on portions of the Atlantic telegraph cable supplied with a potassium wire in lieu of copper, I discovered, by immersing it in water for a continuous period of twenty-three weeks, and subjecting it to a pressure of three tons per square inch, that it was perfectly insulated; but from this date the insulator appeared to deteriorate, and at the twenty-fifth week, I discovered that the moisture had reached the centre of the core, consequently decomposing the potassium. To obviate this difficulty I immersed fresh pieces of cable in bisulphuret of carbon and the chloride of sulphur, which had the effect of shrinking and closing up the pores and rendering the insulator thoroughly impervious; this, in fact, vulcanized the insulating core to about $\frac{1}{20}$th of its own thickness. Having proved by experiments that my system of preserving the insulating medium from moisture is effectual, I beg to bring such a valuable fact to your notice.

The result of these trials was brought foward at a meeting of the Institution of Civil Engineers *prior* to the laying down of the Atlantic Cable, and with the view of deterring the Atlantic Telegraph Company from sinking their cable in its then inefficient state. The subject was discussed at a meeting of the Company, but, unfortunately, it was over-ruled by Mr. Whitehouse, the company's electrician, although the fact of such inefficiency was apparent to all practical men. The result of applying such a cable for deep-sea purposes proves the accuracy of my experiments; but at a loss of from £400,000 to £500,000.

The main practical point to be considered in the construction of telegraphic cables is, combined with sufficient strength, *perpetual* isolation. It is not by outer coverings of tarred and greased hempen twine or such other soft materials that the core is to be perfectly insulated, but by applying to the insulating material, whether fillets or coverings of india-rubber or gutta-percha, a pressure of four to six tons per inch at the time it is encased round the copper conductor. This pressure I obtain by passing the conductor between a series of powerful double rollers; and to prevent both longitudinal strain upon the conductor and abrasion, fibres are incorporated in the outer coating of the insulating material, producing a body of such consistency and power of resistance to any alteration of form as is not inherent in the pure insulating substance, such as gutta-percha or india-rubber alone.

The adoption of the above means of constructing telegraphic cables will necessarily produce the following inevitable results:—

1st. As gutta-percha and india-rubber *decompose*, *absorb moisture*, and are *injured by heat*, which in long lengths of telegraphic cables greatly reduce their insulating properties, and which have been the great cause of failure, the cold vulcanizing renders the insulating core homogeneous, shrinking and closing up all pores and joints, besides rendering the insulator *proof* against moisture, decomposition, abrasion, or injury by tropical heats.

2nd. The great advantage of laying on the coatings or fillets of india-rubber longitudinally, and submitting them to cold vulcanization, must be apparent to all, over the expensive and ineffectual system of spirally winding them round the wire, making a join every quarter of an inch, or 253,440 joins in a mile, which are the elements of its own destruction.

3rd. The rapid rate at which these cables can be made will reduce the expense 25 per cent.

4th. From their lightness and great longitudinal strength there will be little or no strain upon the conductor, therefore the paying-out apparatus will be simple and inexpensive.

5th. Telegraphic wires insulated with india-rubber, and subjected to cold vulcanization, will resist 250° of heat, and may be punctured fifty times in the space of an inch without admitting any water to the wire, from its superior power of elastic contraction caused by vulcanization. To the public this is a matter of the utmost importance, inasmuch as one pin-hole in the Atlantic cable would render it unserviceable.

In conclusion, I believe that a cable constructed on these principles will eventually be the only one capable of permanently resisting the severe natural actions to which all submarine wires are subject, when submerged at great depths and lengths.

I may add, that I have met with the same difficulty in introducing the above system of constructing telegraphic cables that I did twenty years ago, in introducing powerful metallic rollers for the coating of cloth with india-rubber, and vulcanizing the surface, first employed by me at the Tottenham india-rubber mills (then known as the London Caoutchouc Company) and now universally adopted.

The coating of telegraphic wires with india-rubber is but a simple affair, compared to coating cloth two yards wide; suitable machinery (which is being constructed) will coat from 250 to 300 miles of perfect vulcanized cable per day.

I have the honour to be, gentlemen,
Your obedient servant,
J. MACINTOSH.

THE ADMIRALTY COMMITTEE ON DOCKYARDS.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—In a late number of your Magazine you honoured the Committee on Dockyards with a notice, giving the names of all the members except one, whom you designate a "foreman" of Mr. Lindsay's. As I was the only member whose name did not appear, I consider myself the person referred to as Mr. Lindsay's foreman. I beg to acquaint you that I *am not* a foreman of Mr. Lindsay's, nor was I *ever* a foreman of Mr. Lindsay's. My profession is consulting engineer. In proof of my position as such, I am prepared to lay before you or any one, if necessary, the fact of my having prepared specifications and superintended the construction both of hull and machinery of 26,001 tons register of screw and paddle steamers during the four years previous to my joining this Committee, which was in July, 1858.—I am, gentlemen, your obedient servant,

ROBT. BOWMAN.

17 Paynton-terrace, East India-road, London,
June 18, 1859.

Proceedings of Societies.

ROYAL AGRICULTURAL OF ENGLAND.

June 15.—At a Weekly Council, held on this day, Mr. Raymond Barker, Vice-President, in the chair, the Earl of Malmesbury, Secretary of State for Foreign Affairs, transmitted the report of Mr. Morgan, Her Majesty's Consul at Bahia, respecting some original deposits of guano (from which nitrate is extracted) existing in the province of Bahia. The Lords of the Committee of Privy Council for Trade transmitted the three boxes of sample of the guano referred to in the above despatch, and requested to be favoured with the result of any experiments that may be made with a view to ascertaining the value of this substance. Mr. Morgan's report states that favourable accounts have been given of the samples already sent to London, Liverpool, and Birmingham. The deposits exist in beds of limestone, some of them extending over 20 square leagues. The most available deposits are found on the road to the diamond districts. The chief drawback is the want of good roads, but that the formation of a railroad is in contemplation. There are also other and almost exhaustible deposits in the neighbourhood of the River San Francesco province of Pianhy. These altogether extend over a territory of upwards of 200 square leagues. The report proceeds to detail the process of extracting the nitre, which is used to prepare gunpowder of a very ordinary quality, and to preserve meat and fish. The report concludes thus:—"From information received from several of the proprietors of those deposits lying in the intended line I believe, with the railroad, the primitive earth or manure could be replaced in England at £7 to £9 per ton. Should the trade in this article increase, either from competition or abundance, it is but natural to suppose it would be placed at a lower figure for the purposes of our commerce, inasmuch as the manure in question contains highly-organised matter with a large quantity of real ammonia and nitrogen, alkalies, magnesia, sulphate, and carbonate of lime." These communications were referred to the Chemical Committee with a view to the samples being analysed by Dr. Voelcker, the Society's consulting chemist.

A letter from Mr. Bullock Webster (dated from Athens) was read, in which he states that he has been devoting attention to the Vine disease, and that the application of sulphur has proved most successful in Greece, and that the same effect had been produced on blighted green crops. He can speak with confidence as to potatoes, beans, peas, fruit-trees, roses, trees, &c., and that he has no doubt of its efficacy as regards both turnips and hops. He also states that the sulphur ought to be applied in a very fine powder in the early stage of the growth of the plant, as soon as any blight shows itself; it is applied either by means of a large tin pepper-box or small bellows (of which he enclosed a sketch). A woman can dress an acre of vines per day. Scarcely any change will be observable in the crop for the first 10 days; after that it becomes healthy. Should rain fall within five days after the application of the sulphur the operation has to be repeated.

A letter was read from Mr. Curtis, the entomologist, respecting the insects forwarded by order of the Council, and by which Mr. Greenwood's mangel wurzel crop had been nearly destroyed. Mr. Curtis states them to be the larvæ of a beetle which has at various times injured the crops of mangel wurzel in Ireland and in France. The beetle is the Silpha opaca, fully described in the Society's journal (vol. viii., page 404, and plate 8, figures 12 to 24).

The Admiralty have issued contracts for eighteen new "gun-vessels"—not "gun-boats," as has been announced. They are understood to have been taken by six builders at the following prices:—Messrs. Green, two, at £24 15s. per ton; Mr. Wigram, four, at £21 10s.; Mr. Mare, three, at £21 10s.; Mr. J. Scott Russell, four, at £21 (not £20 10s. as was stated in the *Times'* City article); Mr. Miller (Liverpool), two, price not stated; Mr. Langley, one, at £24; Mr. Pitcher, one, at £25; and Mr. White (Cowes), one, at £25. These vessels will not differ materially in form, we believe, from existing gun-vessels, except in being lengthened several feet at the bows.

NOTICES.

We have been compelled to defer the publication of several articles, and of letters from Captain Selwyn, R.N., Mr. Charles Clifford, and others, in consequence of the appearance of the title-page, preface, and index to this volume in the present number.

Scoto-American.—Your letter shall be taken into consideration.

The MECHANICS' MAGAZINE will be sent free by post to all subscribers of £1 1s. 8d., annually, *payable in advance.* Post Office Orders to be made payable to R. A. Brooman, at the Post Office, Fleet Street, London, E.C.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 5d. per line for any number of insertions less than 13; for 13 insertions, 4d. per line; and for 52 insertions, 3d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

Special Arrangements for larger or Serial Advertisements. To ensure insertion, Advertisements must reach the Office by 5 o'clock on Thursday evening each week. None can be received after that time for the ensuing number.

Our Weekly Gossip.

SINCE the letter from Mr. Robert Bowman, which appears in another column, was put in type the following autobiographical narrative has been received from that gentleman:—"17 Paynton-terrace, East India-road, 20th June, 1859. Gentlemen,—I would not have troubled you with another communication at so early a date after mine of the 18th inst., but for an error which crept into that letter inadvertently, viz.,—I stated that a given tonnage of steam-ships had been built under my inspection during *four years* previous to my appointment on the Dock-yard Committee. I ought to have said *five years* previous to that time. I may now take occasion to observe that during the five years I did superintend the construction of five steam-ships for Mr. Lindsay, and no doubt owe principally to that gentleman my appointment on the committee. That you may have some knowledge of my standing in my profession, I beg to refer you to the Repository of Inventions for 1824, where, if I mistake not, you will find a patent taken out by me for an elastic "Stopper for Chain Cables." At that time I was manager at the engine works of Wm. Simson and Co., Aberdeen, which works were greatly enlarged under my management, and are now known as the "York Place Iron Works." I continued in the management of these works until the end of 1838, after which, under the firm of Bowman, Vernon, and Co., engineers and iron shipbuilders, I built several iron sailing ships and some small steamers. I left that firm and went into Staffordshire. If you refer to the July and August numbers of your Magazine for 1847, I think you will find a few experiments made by me on cast iron, chilled and unchilled. After leaving the crane foundry, where I was manager, I joined the firm of G. B. Thorneycroft and Co., as their superintending engineer. If you turn to the *Mining Journal* of June 8th, 1850, you will find a letter of Mr. Thorneycroft's to a railway official, in which Mr. T. makes mention of what my ability and character were in his estimation. I left that firm in the beginning of 1853, and in May of that year commenced my present practice of consulting engineer. I regret having occasion to trouble you with such lengthened and minute detail which cannot interest at all, but as I have to depend upon my professional knowledge and position for my living, I should not wish that either your mind or that of the public, into whose hands your publication falls, should have the impression that one of the members of the late Dock-yard Committee was only a foreman of Mr. Lindsay's. I am, gentlemen, yours respectfully, ROBERT BOWMAN."

A case occurred at the Guildhall Police Court this week which will interest our readers. Robert Marks, who is described by the newspaper reporters as "a shrewd, intelligent, middle-aged man, of gentlemanly exterior," and a publisher, residing at Brighton, was brought up on a warrant, charging him with obtaining large sums of money by means of false pretences. Among the witnesses examined was Mr. Richard Cort, of Barnsbury-park, Islington, the son of Henry Cort, the inventor of puddling and rolling bar-iron. He said: "I know the prisoner. I employed him to collect subscriptions to a testimonial fund which was being raised in acknowledgment of the services of my father to the British nation. That was in August, 1856, and I agreed to give him 50 per cent. on all he collected, and that was to cover all the expenses and to repay him for devoting the whole of his time to the object; but within a few weeks after I had some suspicion of him, and discharged him. The discharge was in writing, and I sent it through the post. I know he received it. During the time he was collecting under my authority I only received two subscriptions from him, and to my knowledge he has collected hundreds of pounds which I have not received. I discharged him on the 22nd of October, 1856." Mr. John Boyne, a merchant, of 2 East India-chambers, Leadenhall-street, said: "In December, 1856, I wrote a letter to the prisoner, asking to whom I should pay a sum of £30 4s., which I had received in behalf of the 'Cort's Testimonial Fund,' in consequence of which he called on me on the 15th of December, 1856, and I handed him a check for £30 4s., which has since been paid at the bank. I took no receipt, because his appearance was so highly respectable that it quite deceived me, and it is not customary to ask for a receipt for charitable contributions." Mr. Richard Cort recalled: "I have not received one farthing of this sum of £30 4s., nor any other sum since the prisoner's dismissal." Prisoner: "This is merely a question of account between Mr. Cort and me, and I shall be able to show that it is a clear case of disputed accounts." The prisoner was remanded till Friday next, when it is expected that important disclosures will be made with regard to the system pursued by the prisoner as a promoter of testimonial presentations.

Patents for Inventions.

PROVISIONAL PROTECTIONS.

Dated February 21, 1859.

474. P. Spence, of Pendleton, Manufacturing Chemist. Improvements in the manufacture of alum, and in the mode of, and apparatus for, condensing or destroying gases arising therefrom.

Dated March 11, 1859.

626. R. Hellard, Ironmonger, of Taunton. Improvements in reaping and mowing machines.

Dated March 18, 1859.

688. R. Clegg, of Islington, and R. Fell, of Limehouse. Improved apparatus for obtaining aerated fresh water from salt water.

Dated March 22, 1859.

730. T. Manlove, of Radford-grove, Lace Manufacturer, and W. Hodgkinson, of New Lenton, Draughtsman, both in Nottingham. A new method of manufacturing plain, figured, striped and plaited textile fabrics in imitation of loom-made fabrics.

Dated April 5, 1859.

852. F. C. Bakewell, of Haverstock-terrace. Improvements in open fire-places. A communication from C. Dodge.

Dated April 15, 1859.

946. G. Abeillou, of Toulouse, Tool Manufacturer. An extensible arching plane.

Dated April 30, 1859.

1082. W. Winstanley and J. Kelly, of Liverpool, Hydraulic Engineers. Improvements in pumps, and gearing and appliances for working the same.

Dated May 3, 1859.

1106. T. W. Miller, of Portsea. Improvements in apparatus for, and mode of, generating steam and economising fuel.

1108. W. Sellers, of Philadelphia, Engineer. Improvements in couplings for shafting. Partly a communication from C. Sellers.

Dated May 10, 1859.

1176. W. O. Bourne, of New York. Improvements in the means of, and apparatus for, separating metals, ores, and other substances of different specific gravities.

Dated May 12, 1859.

1194. W. Warne, J. A. Fanshawe, J. A. Jaques, and T. Galpin, of Tottenham, India Rubber Manufacturers. An improved compound or preparation of materials for, and mode of, and apparatus for, covering and insulating wires or conductors used for telegraphic or electrical purposes.

Dated May 18, 1859.

1230. A. R. Terry, Civil Engineer, of Great George-st., Westminster. Improvements in apparatus for sawing and cutting up loaf sugar.

Dated May 20, 1859.

1244. G. J. Parfitt, of Bath, Surveyor. Improvements in gas burners.

Dated May 21, 1859.

1252. A. L. Taylor, of Ludgate-hill. An improved form of harmonican pianoforte.

Dated May 23, 1859.

1260. J. H. Brierley, Manufacturer, of Halifax, and G. Old, Warehouseman, of Birmingham. A brace buckle.

1262. R. V. Leach, of Briton Perry, Glamorgan, Tin-plate Manufacturer, and T. W. Willett, of Pont-Neath-Vaughan, Brecon, Civil Engineer. Improvements in the manufacture of tin plates and terne or leaded plates, and in the apparatus connected therewith.

1264. G. Burnell, of East Hoathly, Sussex, Gentleman. An improved preparation or medicine for the cure of ague.

1266. H. A. Cooke, of Chancery-lane. Improvements in omnibuses.

1268. C. P. Moody, of Corton Denham, Somerset, Gentleman. Improvements in machinery for the manufacture of matting or fabric from straw and other vegetable fibres, and rods or bars of wood and metal.

1270. F. J. Bramwell, of Great George-st., Westminster. Improvements in apparatus for raising ships and vessels out of the water. Partly a communication.

1272. N. S. Dodge, of St. Paul's-churchyard, Merchant. Improvements in treating waste vulcanized india-rubber. A communication from H. L. Hall.

1274. N. S. Dodge, of St. Paul's-churchyard, Merchant. Improvements in finishing, colouring, and varnishing india-rubber goods, and similar manufactures. A communication from H. L. Hall.

Dated May 24, 1859.

1276. J. Stansfield, of Batley, York, Woollen Spinner. Improvements in the permanent way of railways.

1278. J. C. Fisher, of Glasgow, Manager. Improvements in preparing paints and varnishes.

1280. J. Gibbs, of Brentford, Civil Engineer. A method of treating coal, shale, lignites, and peat, in order to manufacture manure.

1282. G. Hadfield, of Carlisle, Varnish Manufacturer. An improved arrangement of heating and evaporating apparatus.

1284. A. J. Sax, of Paris, Musical Instrument Maker. Improvements in wind musical instruments.

Dated May 25, 1859.

1288. D. S. Price, of Green-st., Grosvenor-sq., Analytical Chemist. Improvements in the production of colours for dyeing and printing.

1290. E. Maw, of Doncaster Iron Works, Yorkshire. Improvements in the construction of metallic bedsteads and other furniture.

1292. A. Prince, of Trafalgar-sq. Improvements in screw propellers. A communication from H. Hirsch.

1294. J. Mallet, of Barnstaple, Watch Maker. An improved regulator for watches, portable clocks, and timepieces.

1296. J. Howard, of Bedford, Agricultural Implement Maker. An improved construction of horse-rake.

Dated May 26, 1859.

1298. J. Webster, of Birmingham, Engineer. An improvement or improvements in pressure and vacuum gauges.

1299. J. Reynolds, of Carthusian-st., Charter House-sq., Gentleman. Improvements in propelling vessels.

1300. H. W. Patrick, of Acton. A new substance or material to be used in lieu of ivory and other like substances.

1301. C. Dorn, of Stuttgart, Wurttemburg, Mining Engineer. Improvements in kilns for baking or burning china, earthenware, and bricks, and for other like purposes.

1302. J. Young, of Wolverhampton, Manufacturer. Improvements in locks, and in the manufacture of knobs for locks and latches, and also in apparatus for preventing draughts, and keeping out wet from doors and windows.

1303. P. Effertz, of Manchester, Mechanical Engineer. Certain improvements in machinery or apparatus for cutting paper, pasteboard, cardboard, and also for cutting or slicing wood into thin scaleboard or veneers, or for similarly cutting other articles.

1304. G. F. Chantrell, of Liverpool, Furnace Engineer. Improvements in the construction of charcoal kilns, and in the manufacture of coolers for charcoal kilns.

1305. W. H. Nevill, of Llanelly, Carmarthen, Manufacturer. Improvements in the manufacture of steel and wrought iron.

1306. J. Draper, of Little Tower-st. Improvements in applying indices to account and other books.

1307. M. Michaelis, of Manchester, Clerk, and R. Kershaw, of Heywood, Manufacturer. Improvements in the manufacture of velvets and other piled fabrics.

1308. J. C. Bent, of Birmingham, Gas Meter Manufacturer. Improvements in gas meters.

1309. W. Wright, of Deptford. Improvements in fastening shirts, collars, and other articles of wearing apparel.

Dated May 27, 1859.

1311. W. Weild, of Manchester, Machinist. Improvements in looms for weaving pile fabrics.

1312. M. A. F. Mennons, of Paris. An improved mode of advertising. A communication from A. Gatte.

1313. P. Aitchison, Brass Founder, and T. Binks, Plumber, of Sheffield. Improvements in self-acting and other water-closets, and in flushing apparatus connected therewith.

1314. L. Farrenc, Gentleman, and B. Subra, Professor of Mathematics, of Paris. Improvements in gas lighting by means of direct carburators.

1315. H. N. Nissen, of Mark-lane, Stationer and Printer. An improvement in book indexes.

1316. G. Hadfield, of Carlisle, Varnish Manufacturer. Improvements in the mode of and apparatus for forming casks or barrels.

Dated May 28, 1859.

1317. B. Samuelson, of Banbury. Improvements in machines for cutting roots and other vegetables.

1318. T. Wilson, of Birmingham, Engineer. Improvements in breech-loading fire-arms and ordnance.

1319. W. Crum, of Thornliebank, Renfrew, Bleacher. Improvements in printing and dyeing textile fibres and fabrics.

1320. W. H. Graveley, of Upper East Smithfield, Engineer. Improvements in apparatuses for purifying and aerating sea water, parts of which may be employed for cooking and baking purposes.

1321. R. A. Brooman, of 166 Fleet-street, London, Patent Agent. Improvements in machinery for cleaning, grinding, and bolting corn and other grain. A communication from J. B. Falguière.

1322. J. Oldbury, of Handsworth, Stafford, Gun Maker. Improvements in breech-loading fire-arms, applicable to pistols, muskets, carbines, and birding or other guns.

1323. J. Bapty, of Leeds, Foreman. An improved mode of, and apparatus for, manufacturing felted cloth.

Dated May 30, 1859.

1324. M. Davis, of Lyon's-inn, Strand, Caoutchouc Wheel Manufacturer. Improvements in the construction of wheels, axles, and boxes for carriages.

1325. A. Smith, Engineer, of Princes-st., Leicester-sq. Improvements in machinery for making lines, ropes, and cables, for telegraphic and other purposes.

1326. W. Grimshaw, of Bowdon, Chester, Gentleman.

Digitized by Google

Certain improvements in machinery for compressing bricks, tiles, artificial fuel, and other similar articles.

1327. E. Breffit, of King William-st., City, Glass Manufacturer. Improvements in machinery or apparatus for the manufacture of hollow corks.

1328. J. Bruce, of Tiddington, near Stratford-on-Avon, Agricultural Implement Maker. An improvement in agricultural drills.

1329. W. Gossage, of Widnes, Chemist. Improvements in the manufacture of iron and steel.

1330. J. Fry, of Wrotham, Sevenoaks, Miller. An improvement in mills for grinding.

1331. O. Maggs, of Bourton, Dorset. Improvements in harrows.

1332. W. Green, of Limehouse. Improvements in washing or purifying and treating sugar.

1333. I. and R. Blackburn, of Long Eaton, Derby, Engineers. Improvements in locomotive or traction engines, and in implements connected therewith for cultivating the soil.

1334. J. L. Norton, of Belle Sauvage-yard, Ludgate-hill. Improvements in machines for stretching and drying fabrics, and in drying wool and other fibres.

1335. A. Mickelthwate, J. Peace, and S. J. Hobson, of Sheffield. Improvements in the coating and covering of metallic springs, steel, iron, and other metal bands for the use of any kind of machinery, driving bands, or straps, ribs suitable for umbrellas and parasols, staybusks, and ribs for stays, hats, bonnets, reeds and crinoline, and articles of dress, and other useful purposes.

1336. E. Leeson, of Derby, Lace Manufacturer. Improvements in machinery for the manufacture of ornamental chenille fringes and braids or other fabrics.

1337. W. Clark, of Chancery-lane. Certain improved means of reefing and shortening sail in ships and other vessels. A communication from E. E. Mulliner.

1338. W. Clark, of Chancery-lane. A new manufacture of leaven. A communication from F. Ludewig.

Dated May 31, 1859.

1340. J. S. Cockings, Civil Engineer, of Birmingham. Certain improvements in the construction of self-adjusting cases for holding and carrying cartridges of various sizes or gauges, parts of which improvements are also applicable to cartridge-carriers now in use.

1341. S. Carr and G. Butterworth, of Leeds, Manufacturers. Improvements in the manufacture of felted cloth, and in the machinery or apparatus employed in such manufacture.

1342. E. A. Wood, of Notting-hill, and M. D. Rogers, of Bromley, Middlesex, Shipwright. Improved apparatus for raising and lowering boats.

1343. J. Wansbrough, of Bridge-street, Southwark, Gentleman. Improvements in the construction of stereoscopes. A communication from E. Moxham.

1344. G. H. Smith, of Manchester. Improvements in sewing machines.

1345. P. Gambardella, of Naples, Engineer. Improvements in obtaining motive power, and in machinery or apparatus connected therewith.

1346. J. J. Lundy, of Manchester, Colour Manufacturer. Improvements in cartridges and gun-wads, for facilitating the loading and lubricating of fire-arms.

1347. A. Suter, of Fenchurch-st. A furniture castor, to be used upon the feet of tables, seats, and all descriptions of furniture or other things.

1348. F. Roberts, of Maiden Newton, and A. Roberts, of Frome, Vanchurch, Dorset. Improvements in apparatus employed for ploughing, tilling, or cultivating land, when steam power is employed.

Dated June 1, 1859.

1349. J. F. Miquel, of Paris. Improvements in trusses.

Dated June 2, 1859.

1351. F. W. Saltonstall, of Northumberland-st., Strand, and A. Bush, of St. John's Wood. An improved machine or apparatus for dredging and excavating.

1352. M. H. Chapin, of Gresham-st., Merchant. Improvements in galloons, tapes, or ribbons, for supporting steel and other hoops used for distending ladies' dresses.

1353. R. K. Whitehead, of Elton, near Bury, Bleacher. Improvements in apparatus to be used in bleaching, dyeing, and extracting the colouring matter from dye materials.

1354. S. and J. Wood, of Manchester, Embroiderers, and P. Billington, of Rusholme, Mechanic. Certain improvements in, and applicable to machines for embroideringI

1355. A. and W. Smith, of Glasgow, Engineers. Improvements in machinery for curing sugar, and for separating solid and liquid substances by centrifugal force.

1356. S. Bury, of Manchester, Manager. Certain improvements in machinery or apparatus for embossing and finishing textile fabrics or other like surfaces.

1357. S. Bury, of Manchester, Manager. Certain improvements in machinery or apparatus for embossing and finishing textile fabrics or other like surfaces.

1358. W. H. Parkes, of Birmingham, Manufacturer, and W. Bagnall, of Birmingham, Plater. A new or improved ventilator for hats and other head coverings, and also for carriages.

1359. T. Whitby, of Millbank-st., and W. Dempsey, of Great George-st., Westminster, Civil Engineers. Improvements in, and applicable to, ordnance and fire-arms, and in the projectiles to be used therewith.

1360. J. B. Pascal, of Paris, Civil Engineer. Improvements in hot-air engines.

Dated June 3, 1859.

1361. J. Wilson, of St. Helens, Manufacturing Chemist. Improvements in the manufacture of carbonate of soda.

1362. J. Edwards, of Aldermanbury. Improvements in the manufacture of anchors.

1363. R. W. Sievier, of Upper Holloway. Improvements in smelting and purifying of iron and other ores.

1364. J. Onions, of Darlaston, Stafford, Engineer. A new or improved steam-boiler.

1365. R. Mushet, of Coleford, Metallurgist. An improvement or improvements in the manufacture of iron and steel.

1366. H. N. Penrice, of Norwich. Improvements in machinery for propelling vessels.

1367. J. Kyle, of Liverpool, Pointsman. Improvements in points for railways and chairs for the same.

1368. J. H. Johnson, of Lincoln's-inn-fields. Improvements in reducing solid substances to powder, and in the machinery or apparatus employed therein. A communication from W. J. Cantelo.

1369. J. J. Baranowski, of Paris, Gentleman. Improvements in railway signal apparatuses.

1370. A. R. Arrott, of Saint Helen's, Chemist. Improvements in the manufacture of soda.

1371. J. Burrow, of Bakewell, Derby, Clerk, and W. N. Wilson, of High Holborn. An improved floor scrubber and sweeper for carpets, floors, lawns, and other such like useful purposes.

1372. A. V. Newton, of Chancery-lane. An improvement in balancing millstones. A communication from J. Fairclough.

Dated June 4, 1859.

1373. H. Crossley, of Failsworth, near Manchester. Improvements in Jacquard machines.

1374. R. Chrimes, of Rotherham, Iron Founder. Improvements in apparatus for supplying water to, and discharging the contents from, urinals, wash-hand basins, and other similar articles.

1375. E. Gill, of Wandsworth, Distiller. Improvements in producing spirit from rice, maize, and other descriptions of grain.

1376. J. Nuttall, of Old Accrington, Beerseller, G. Riding, of Clayton-le-Moors, Medical Botanist, and W. Coulthurst, of Old Accrington, Chemist. An improved size powder, to be used in sizeing cotton linen or other warps for weaving.

1377. G. Davies, of Serle-st., Lincoln's Inn. An improvement in wearing apparel. A communication from G. J. J. Laury.

1378. J. and W. Wood, of Nottingham, Lace Manufacturers. A peculiar mode or method of dyeing lace or other fabrics, and making the same into bonnet and cap fronts, or other articles.

1379. C. James, of Aberdare, Agent. An improvement in the manufacture of railway chairs.

Dated June 6, 1859.

1382. G. Davies, of Serle-street, Lincoln's Inn. Improvements in paddle wheels and screw propellers for steam vessels. A communication from A. Jouan.

1384. W. Green, of Victoria-st., City. Improvements in mowing machines.

Dated June 7, 1859.

1386. K. H. Cornish, of Essex-court, Middle Temple, Surgeon. Improvements in bedsteads, sofas, couches, and chairs, applicable to other seats or reclining surfaces.

1388. W. B. Nation, of Rotherhithe, Analytical Chemist. Improvements in the manufacture of superphosphate of lime.

1390. R. Barclay, of Bucklersbury. Improvements in the manufacture of paper from which writing or other inks cannot be expunged or extracted without detection.

1392. R. R. Fairgrieve, of Boston, U.S., Machinist, and S. Bathgate, of Selkirk, Engineer. Improvements in machinery or apparatus for winding yarns or thread.

Dated June 8, 1859.

1394. J. Henderson, W. Henderson, and T. Bagley, of Durham, Carpet Manufacturers, and S. Holdsworth, of the same place, Engineer. Improvements in looms for weaving, some of which improvements are applicable to other purposes.

1396. J. B. Howell, of Sheffield, Steel Manufacturer, J. Hick, of Great Bolton, Ironfounder, and W. Hargreaves, of the same place, Ironfounder. Improvements in apparatus for applying heat to steam or other boilers or vessels, and for facilitating the combustion of gases and smoke.

1398. J. B. Molozay, of Paris, Gentleman. New means of manufacturing velvet.

1400. A. V. Newton, of Chancery-lane. Improvements in gas meters. A communication from W. Richards.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(*From the London Gazette, June* 21, 1859.)

342. M. Curtis and J. Miller. Spinning.
346. J. Smith. Combing fibrous substances.
350. J. Hosking. Lamps.
357. A. Clark. Shutters and blinds.
362. J. S. Joseph. Coke ovens.
373. H. P. Burt. Railway carriages.
377. R. J. Ellis. Lifting submerged bodies.
390. C. Jackson. Pianofortes.
392. H. Ransford. Building ships.
400. J. and J. Bennett. Refrigerators.
491. G., G. W., and J. Betjemann. Book-slides.
410. C. Sanders. Photographic pictures.
411. J. Wright. Rolling steel and iron wire.
412. J. L. Clark. Railway signals and switches.
414. R. Clegg, F. Angerstein, and W. Page. Soap.
418. R. Mushet. Steel, iron, and cast steel.
423. G. Bedson. Joining wire.
427. R. Cookson and C. W. Homer. Bricks, tiles, &c.
429. R. J. S. Pearce. Weighing and dynamic machines.
445. P. E. Fraissinet. Iron.
453. G. Wallis. Engraving.
456. W. Clark. Pressure gauges. A commnnication.
458. P. A. J. Dujardin. Telegraphs.
464. C. F. Vasserot. Wire ropes. A communication.
483. W. S. Clark. Railways. A communication.
489. A. W. Smethurst. Driving looms.
505. J. H. G. D. Wagner. Cleansing water.
506. J. Dale. Caustic alkalis.
550. R. H. Collyer. Paper.
779. C. L. Roberts. Cigars.
797. J. Cartwright. Crushing clods.
1026. W. Moxon and J. J. Bennett. Moving heavy bodies.
1158. J. Luis. Horse machine. A communication.
1173. G. Bell. Matches or fusees.
1194. W. Warne, J. A. Fanshawe, J. A. Jaques, and T. Galpin. Insulating wires.
1286. M. A. F. Mennons. Moulds for casting. A communication.
1317. B. Samuelson. Cutting roots.
1319. W. Crum. Printing and dyeing.
1321. R. A. Brooman. Cleaning, grinding, and bolting corn. A communication.
1336. E. Leeson. Chenille fringes and braids.
1378. J. and W. Woo . Dyeing fabrics.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed June 17, 1859.

2900. J. Mac Kenzie.
2902. J. Taylor.
2908. S. Hunter.
2910. J. Ronald.
2914. W. E. Dando.
2924. M. Kenney.
2933. J. Ronald.
2958. W. A. Gilbee.
2961. C. M. A. Marion.
2997. J. W. Duncan.
30. J. Furnival, T. Furnival, J. Derbyshire, and F. J. Emery.
40. R. Rumney and W. S. Macdonald.
82. B. Robbin.
100. R. Mushet.

INTRODUCTION.

THE following tables contain a mass of information which has been long desired by many scientific men.

Notwithstanding the rapidity with which steam vessels have increased in number of late years, but little regard has been shown to the conditions on which their economical construction depends; and every attempt to improve their economy and efficiency has been baffled by the want of reliable data. The persons whose good intentions have thus been frustrated, have instinctively turned towards the Admiralty, and requested to be furnished with that body of invaluable facts which the steam-ships of the Royal Navy have supplied. The official reserve of the Department, however—maintained in this case, we believe, too tenaciously—has hitherto effectually prevented their publication. It is not possible to keep such information absolutely secret in this country, and accordingly we have ourselves been in possession of the Admiralty tables for a considerable period, having obtained them through a channel which those who know us best would least suspect. But we have not, of course, felt at liberty to publish them against the will of the gentlemen who are responsible for them.

During the last month or two, however, the navy has been much thought of, and the desirability of obtaining the data kept back by the Admiralty has been so strongly felt that several members of the two Houses of Parliament determined to wait in a body upon Sir JOHN PAKINGTON to urge their production. The necessity for such cumbrous proceedings is now fortunately removed, by the publication of the whole of the Admiralty Tables in the following pages, the present Lords of the Admiralty, through their Secretary, the Right Hon. H. L. CORRY, M.P., having given the necessary sanction.

The first portion of these tables has been published, in an imperfect form, before; but in order that our readers may enjoy the full benefit of their Lordships' complaisance, we have given both sets complete. As such data would be almost valueless were they printed inaccurately, we have bestowed the utmost care upon the proof-sheets, and now put them forth in the confidence that they are as reliable as the original tables themselves. We believe the facts contained in them, however severely analysed, will redound to the credit of those who have had laid upon them the heavy responsibility of constructing Her Majesty's Steam Navy.—E. J. R.

(Official Paper prefixed to the first set of Tables.)

ON THE INTRODUCTION AND PROGRESSIVE INCREASE OF SCREW PROPULSION IN HER MAJESTY'S NAVY.

ALTHOUGH various propositions for many years were made from time to time to use the screw as an instrument of propulsion, and a great variety of experiments tried in boats and small vessels, yet neither the reasoning of the projectors nor the results of their experiments appear to have carried conviction to the minds of most men that this kind of propeller could be usefully employed, or at all events that it could successfully compete with the paddle-wheel.

The immediate cause of its introduction into the navy was the successful performance round Great Britain and elsewhere of the Archimedes, a vessel of 237 tons, built in the year 1838 by the Screw Propeller Company, with a view of ascertaining the value of the invention. She was first tried against a paddle-wheel vessel in 1840, and the results of the trials are contained in the following report, the first official one made to the Board on the subject of screw propulsion:—

SIR, Dover, May 2nd, 1840.

In pursuance of the instructions of the Lords Commissioners of the Admiralty, as conveyed to us in your letter dated 25th ultimo, directing us to examine and report upon the principle on which the Archimedes steam vessel is propelled, we beg to state that we have made such experiments as were practicable, and we request that you will be pleased to submit to their lordships the following report.

On our arrival at this place we made arrangements with Commander Boteler, by which the Widgeon Mail Steam Packet was placed at our disposal. The following statement shows the comparative size, power, and immersion of the two vessels:—

Names.	Tonnage.	Diameter of Cylinders	Length of Stroke	Mean Draught of Water.
Widgeon.....	162	39 inches	3 feet 1 inch	7 feet 3 inches
Archimedes.....	237	37 inches	3 feet	9 „ 4 „

The Widgeon is the fastest packet upon the Dover Station. She has 10 horses power more, and 75 tons burthen less, than the Archimedes; and the mean draught of water of the former is 2 feet 1 inch less than that of the latter.

EXPERIMENTS.

1.—Our first trial was upon a run of 19 miles upon a W. S. W. course from Dover Roads, with a light breeze aft and smooth water, but without sails. The engine of the Archimedes worked 27 strokes a minute, and the speed of the vessel was 8½ knots per hour. The Widgeon performed the whole distance in six minutes less than the Archimedes.

2.—In returning the above 19 miles to Dover Roads, against a moderate head wind, without sails, the engine of the Archimedes worked 26 strokes per minute, and her speed was from 7½ to 8 knots per hour. The Widgeon performed the distance in 10 minutes less than the Archimedes.

3.—The third experiment was a run of 19 miles, from Dover Roads to Calais Roads, in a perfect calm, with the sea smooth as glass. Archimedes engine worked 27 strokes per minute, and her speed was from 8½ to 9 knots per hour. The Widgeon performed the distance in 3½ minutes less than the Archimedes, and the whole time occupied by the latter on this trial was 2 hours 9½ minutes.

4.—In returning the above 19 miles back to Dover Roads the weather was dead calm, and the sea smooth as before. The French Mail Packet, called La Poste, started at the same moment. Speed of the Archimedes and her engine as before. Widgeon ran the distance in 4 minutes less than Archimedes, and the Archimedes in 25 minutes less than La Poste. The latter has engines of only 50 horses aggregate power.

5.—On this trial there was a fresh breeze at east, and moderate sea. Both vessels set the whole of their sails, the Archimedes carrying much more canvass than the Widgeon. The run was as before, from Dover to Calais, 19 miles close hauled. Archimedes engine from 27 to 28, and her speed from 9 to 9½ knots. Archimedes ran the distance in 9 minutes less than the Widgeon.

6.—In returning to Dover with a fresh breeze abeam and all sails set, Archimedes engine 28, and speed 10 knots, she performed the distance in 5½ minutes less than the Widgeon.

REMARKS.

These trials clearly prove that the speed of the Archimedes is slightly inferior to that of the Widgeon in light airs or calms, and in smooth water; but as the steam power of the former is 10 horses less, and her burthen 75 tons more than the Widgeon, it is evident that in these vessels the propelling power of the screw is equal, if not superior, to that of the ordinary paddle wheel. In this respect, therefore, Mr. Smith's invention may be considered completely successful.

It is also plain, from the second trial, that in the steaming against even a light air of wind, the low masts and snug rig of the Widgeon gave her an advantage over the Achimedes, with loftier masts and heavier rig; and although the prevalence of calms prevented our trying them farther upon this point in blowing weather, we are satisfied that in strong breezes the advantage of the Widgeon's low rig in going head to wind would be still more apparent.

On the last two trials, however, the power of the sails operated strongly in favour of the Archimedes, as she then beat the Widgeon, and made the passages between Dover and Calais in less time than it has ever been performed by any of Her Majesty' mail packets. The Archimedes went upon this occasion from Dover to Calais in 2 hours 1 minute, and returned in 1 hour 53½ minutes.

There are two points of great practical importance respecting the screw propeller which ought not to pass unnoticed. First, the noise made by the spur-wheels used in giving the necessary velocity to the propeller shaft. Secondly, the liability of those wheels to rapid wear, and to accidental derangement. The noise alone, we conceive, would prevent its being applied to any of Her Majesty's packets in particular. Mr. Smith, however, proposes to obviate this objection by substituting spiral gearing in lieu of the present cogs; and a model of this method will be submitted to their lordships with this report. As it is the intention of Mr. Smith shortly to make trial of this alteration, we abstain from giving any opinion upon its merits at present.

It is, however, in propelling vessels of war that the value of Mr. Smith's invention will probably be experienced. In such cases, the rumbling noise

Digitized by Google

in the ship made by the spur-wheels is of no great moment, even if it cannot be overcome; for outside the vessel, this noise is not audible to so great a distance as that made by the common paddle-wheel. A ship fitted with the screw propeller may be used either as a sailing or a steaming vessel, or as both, if required; for we ascertained by experiment that the engine can be connected or disconnected with ease, and in any weather, in two or three minutes. In carrying a press of sail, the inclination of the ship does not diminish the propelling power of the screw, nor lessen the ship's way, as with the ordinary paddle-wheel. The getting rid of paddle-boxes also leaves the broadside battery altogether clear of obstruction, and in boarding an enemy's vessel would allow of the ships lying close alongside of each other.

In conclusion, it is proper to state, that the operation of the screw facilitates the steering, and accomplishes the backing of the ship as easily as the common paddle-wheel.

We have the honour to be, Sir,

Your most obedient Servants,

(Signed) E. CHAPPELL, Captain. T. LLOYD.

The Secretary of the Admiralty.

It is obvious that in the Widgeon and Archimedes, which differed materially both in size and form, an exact comparison could not be made between the performance of the screw and that of the paddle; but the result of the trials clearly showed, especially when the peculiar fitness of the screw for war purposes was taken into consideration, the propriety of trying this new instrument in a less equivocal manner.

With this view the Rattler was ordered to be built, and, that the experiment might be conclusive, so far as a trial between two vessels could make it so, she was constructed on the same lines as the Alecto, the after part being lengthened for the insertion of the screw, and fitted with engines of the same power, and on a plan which had been previously tried in paddle-wheel vessels.

The river trials of the Rattler lasted from October, 1843, to the beginning of 1845, and from them it was clearly seen that the screw might be advantageously reduced from two half turns to about one-third of this length, an alteration which greatly reduced the weight, facilitated the operation of shipping and unshipping, and appeared to render unnecessary the wounding to so great an extent the after part of the vessel. Before this last point was decided, it not being evident that the good performance of the shorter screw was not attributable to the greater clearance which the reduction of its length had caused, the screw aperture was partly filled up in a temporary manner, so as to leave the shorter screw the same clearance as the longer one originally had. The result of this experiment showed that the screw aperture in future vessels might be constructed of very moderate dimensions without lessening the effect of the propeller.

It was also evident from these trials that the screw, as an instrument of propulsion in smooth water, was not inferior to the paddle-wheel.

In the early part of the year 1845 the Rattler proceeded, in company with the Victoria and Albert, and the Black Eagle, from Portsmouth to Pembroke. When rounding the Land's End, and steaming against a strong head wind, both these vessels, as might be expected, showed a great superiority, their power being much greater than the Rattler's in proportion to their resistance, and their paddle-floats being constructed on the vibrating principle. This comparative failure of the Rattler made an unfavourable impression on the public mind as to the efficiency of the screw against wind and sea in heavy weather, and this impression in some degree still remains, although no conclusive proof of its inferiority in this respect has yet been afforded; for in the subsequent trials of the Rattler with the Alecto at sea, against strong head winds, the only occasion on which the screw has been fairly tried under such circumstances against the paddle-wheel, no decided advantage on either side seems to have obtained, the advocates of the screw and those of the paddle respectively claiming the superiority, while in fine weather the screw is admitted to have had some advantage over the paddle.

The Rattler was next tried against the Vesuvius in a run from the Thames to Leith, and showed in respect of speed a decided superiority over the paddle-wheel vessel, whose power, as compared with her tonnage, was greater than that of her competitor.

Before joining the squadron under the command of Rear Admiral Hyde Parker, in July, 1845, the Rattler was employed to tow the Erebus and Terror to the Orkney Islands, and she appears to have performed this service to the satisfaction of Sir John Franklin.

Before this time, however, the Bee was constructed with both screw and paddle-wheel for the instruction of the officers of the Royal Naval College, the Dwarf purchased, the conditional speed of 12 miles per hour having been realised, and the Fairy built for the use of Her Majesty; but although the results of the experiments made upon the two latter vessels threw some light upon the action of the screw, and satisfactorily showed that by its means a comparatively high rate of speed could be obtained, yet they could scarcely be regarded as proper data on which to proceed in the construction and fitting of larger vessels.

Some private companies also were led to entertain so favourable an opinion of the screw that they ventured to try it; two of them on a large scale. The Great Britain, of 3,000 tons, arrived in the Thames in January, 1845, and the Great Northern, of 1,515 tons, two years previously. Neither of these vessels was successfully worked for any length of time, the former having been wrecked and the other broken up, but the results obtained, as regards the application of the screw, were considered satisfactory.

These results, probably, together with those obtained from the preliminary trials of the Rattler, and, above all, the favourable reports by naval officers of her performance at sea, induced the Board, in 1845, when the steam navy was about to be considerably increased, to determine that the screw should be adopted. They determined at the same time that the engines should be so constructed that every part of the machinery would be below the water line, an important deviation from the practice which had previously existed, and one which must be regarded as a great step towards rendering steam vessels fit for all the purposes of war. The Board likewise ordered the screw and its fitting to be so arranged, that the operation of shipping and unshipping might be easily performed in any weather, thus rendering the vessels, as far as practicable, perfect sailing ships whenever steam power was not required.

It thus became necessary, in order to fulfil the various requirements, to devise new forms of engines and new modes of application, there being at that time no kind of engine which would effectually answer the purpose. All the eminent marine engineers in the country were therefore called on to propose that construction and arrangement of engine which they might severally think the best adapted, the dimensions of the propeller, and the number of revolutions it would be required to make, being furnished for their guidance, and the necessity of keeping the whole of the machinery below the water line being insisted on. Beyond these necessary conditions the manufacturers were left unfettered, and they, as might be expected, seeing a new and wide field open for their exertions, submitted a great variety of designs, the result of their great experience and mechanical ability.

These designs differed widely from one another; some were with and some without gearing, and many of them appeared to possess great merit. Of these, selections were made, giving to nearly all the most eminent engineers an opportunity of carrying into effect one at least of the plans which they severally proposed, and in no instance giving orders for more than two engines of the same description—a decision which seems to have been judicious, when it is borne in mind that little experience had then been acquired in this novel application of steam power.

In the year 1845 tenders were accepted for fifteen pairs of screw engines for vessels of various dimensions, and, on the suggestion of the Harbour Defence Commission, eight pairs for what were originally termed block ships, four of them being line-of-battle ships and four frigates. The good performance of the former class seems to have altered their original destination from mere floating batteries to sea-going ships, calculated to

Digitized by Google

serve with advantage in conjunction with a fleet. Of the frigate block ships, one only out of the four has been ordered to be fitted, and with smaller engines than those originally intended for her. She is not yet completed.

In order still further to test the comparative value of the screw, one paddle-wheel vessel, the Basilisk, was ordered to be built on the same lines as the Niger, and to be fitted with engines of the same power. The result of the trials recently made between these two vessels may be shortly stated. In fine weather, when equal engine-power was exerted, there was little difference of speed, and when sail could be used the advantage was in favour of the screw. There was no opportunity of trying the vessel's head to wind in heavy weather, an important point which hitherto remains undecided by actual experiment.

The expenditure of coal was much greater in the Niger than in the Basilisk, but this disadvantage arose from the construction of the boilers and engines, and not from the difference between the propelling instruments.

As far as trials have been made of the various kinds of screw engines, success to a greater or less degree may be said to have been the result of all; certainly none of them can be regarded as failures; but the pecuniary loss sustained by most of the manufacturers, and the great anxiety felt by all, can be fully appreciated by themselves alone.

Sufficient experience has not even yet been acquired for the basis of a sound opinion as to the particular form of engine which should be adopted, but the selection may now be confined within comparatively narrow limits, and experience already points out the strong probability that gearing may be altogether dispensed with, thus entirely obviating the noise so much objected to in the first screw vessel, increasing the simplicity of the machinery and reducing its bulk and weight.

One important fact, however, which during the early trials of the screw most persons doubted, has been incontestibly proved, and has already led and is calculated to lead still further to a very extensive application of the screw as an auxiliary. It has been established beyond all question that it is unnecessary to adopt complex contrivances for altering the angle of the screw, or to use, as was done in some private vessels, differential gearing, to enable the engines to work advantageously under the varying velocity of the vessel, occasioned by using the sails to a greater or less extent in conjunction with steam-power. If, for example, an engine and screw be arranged to drive a vessel at the rate of five knots, the number of strokes given out by the engine will not be inconveniently increased, or the effect of the screw diminished, when by the addition of sail power the rate of the vessel is increased to 10 knots, the simple screw thus becoming a convenient and efficient auxiliary in all classes of ships, and producing, whenever used in conjunction with sail power, a higher rate of speed than could be obtained under the same circumstances by sail alone. This view is confirmed by the successful performances of many private vessels fitted with auxiliary power. The small vessels first built traded to ports at no great distance, but their voyages have already been extended to Constantinople; and it now seems highly probable, judging by what has been accomplished, that fine sailing vessels fitted with auxiliary screw power will be found able, if not to rival, at least to approach, full-powered and expensive steamships, in respect of their capability of making a long voyage with certainty, and in a reasonably short time.

Another application of the screw, although inferior in importance to its application as a propeller to ordinary ships, is certainly deserving more attention than has hitherto been paid to it, namely, as a manœuvrer to those large ships in which engines of considerable power cannot be placed, or in which it is considered unadvisable to do so. No doubt can be entertained of the efficiency of such an instrument worked by an engine of even 50 horses power. The full extent, however, of its utility cannot, perhaps, be thoroughly appreciated until it shall have been extensively tried in Her Majesty's navy.

The proper form of the run of screw vessels being at the time of their introduction, and for some time after, a matter rather of speculation than a deduction from known principles or facts, a wide difference of opinion on this important point obtained among those who were engaged in designing these vessels; and the Board, in order to ascertain within certain limits the form which ought to be adopted, directed some experiments to be made on the Dwarf. These experiments were carried out by attaching in a temporary manner to the iron plate some pieces of wood, so as to render her afterbody as full as that of any of the vessels then in progress. The great reduction of speed from 9 knots to less than 4 knots caused by this alteration, unequivocally showed the impropriety of adopting such a form; and all the vessels then in course of construction, except those not sufficiently advanced to render necessary any alteration, were to a greater or less extent improved in the form of their stern immediately before the screw aperture.

The great importance, or rather the necessity, of introducing forms calculated to aid the action of the screw, cannot be questioned in those cases in which a high speed is regarded as indispensable, it being evident that in such cases a proper form is also indispensable, for without it the object of high speed is not attainable; but even when a moderate speed only is required, a suitable form, although not, as in the former case, absolutely necessary for obtaining the required speed, will be seen to be of greater importance than is perhaps commonly supposed, by a consideration of the great waste of power and its attendant evils occasioned by the adoption of the contrary form. If, for example, a ship, which, if of the proper form, would be propelled at 7½ knots, is propelled at 6 knots only, about one-half of the engine power is thrown away, thus wasting half the original cost of the engines and boilers, incurring double the current expense of wear and tear, consuming double the quantity of fuel, and losing the advantage of dispensing with half the weight of engines, boilers, and coals, and reducing by one-half the space which they occupy in the ship; or if the weight and space were not calculated to produce serious inconvenience, throwing away the capability of carrying fuel for perhaps three times the number of days. Probably such considerations as these induced the Board to order the afterbodies of so many screw vessels to be improved, with a view of insuring advantages which were neither doubtful nor of small moment, and which appeared to outweigh the expense of making the necessary alterations. Subsequent experience clearly proved the soundness of the views thus carried out.

The following table contains some particulars of all the screw engines which have been ordered, as well as an account of the alterations which from time to time have been made in their application, and of the result thereby produced.

It will be seen that the screw engines ordered from—

1841 to 1844	amount to...	8
in 1845	„	26 including Erebus and Terror
in 1847	„	9
in 1848	„	2 for Pinnaces of Investigator and Research
Total number ...		45

The numbers in the last column of the table, and in the column next but one preceding it, show approximately the relative excellence in respect of speed, of the forms of the various ships, conjointly with the relative efficiency of the propeller, as adapted to each of them.

The formulæ by which the calculations are made are founded on the assumption that the resistance of a ship varies as the square of her velocity, and therefore that the power required to produce that velocity varies as the cube, and that the useful effect of the engine, that is, the effect which remains after deducting the power absorbed in overcoming friction, working air pumps, &c., bears a constant ratio to the power developed in the cylinder, known by the term "Indicated Horse Power." The resistance is, in the first of these columns, assumed to vary, *cæteris paribus*, as the area of the midship section, and in the last column as the cube root of the square of the displacement.

None of these assumptions, however, more especially the last two, are absolutely correct, but probably they are not so far from the truth as to render useless and uninteresting a comparison, of which they are the basis, made between the performances of any two screw ships, while between two vessels which do not materially differ in engines and displacement, or in the area of their midship sections, such a comparison is not only highly interesting, but it may prove of great value in pointing out the forms of ships and proportions of propellers which ought to be adopted. In some striking cases it is scarcely necessary to make any other comparison than that of speed. For example, the Teazer, after her form had been improved, went above a knot an hour faster with 40 horse engines than she had previously gone with engines of 100 horse power. Again, these engines of 100 horse, when transferred to the Rifleman, a vessel approaching to double the tonnage, drove her, after her form had been altered, as fast as she was previously driven by engines of double the power, and nearly 2 knots faster than the same engines drove the smaller vessel before the alteration of her after-body.

(Official Paper prefixed to second set of Tables.)

RESULTS OF TRIALS MADE IN H. M.'S SCREW SHIPS AND VESSELS.

(BEING A CONTINUATION OF THE TABLES PRINTED MAY, 1850.)

THE numbers in the last two figure columns of the Table show approximately the relative excellence, in respect of speed, of the forms of the various vessels, conjointly with the relative efficiency of the propeller, as adapted to each of them.

The formulæ by which the calculations are made are founded on the assumption that the resistance of a vessel varies as the square of her velocity, and therefore that the power required to produce that velocity varies as the cube, and that the useful effect of the engine, that is, the effect which remains after deducting the power absorbed in overcoming friction, working air-pumps, &c., bears a constant ratio to the power developed in the cylinder, known by the term "Indicated Horse Power." The resistance is, in the first of these columns, assumed to vary, *cæteris paribus*, as the area of the midship section, and in the last column as the square of the cube root of the displacement.

None of these assumptions, however, more especially the last two, are absolutely correct, but probably they are not so far from the truth as to render useless and uninteresting a comparison, of which they are the basis, made between the performances of any two screw vessels; while between two vessels which do not materially differ in engines and displacement, or in the area of their midship sections, such a comparison is not only highly interesting, but it may prove of great value in pointing out the forms of vessels and proportion of propellers which ought to be adopted. In some striking cases it is scarcely necessary to make any other comparison than that of speed. For example, as may be seen in the table printed in 1850, the Teazer, after her form had been improved, went above a knot an hour faster with 40 horse engines than she had previously gone with engines of 100 horse power. Again, these engines of 100 horse, when transferred to the Rifleman, a vessel approaching to double the tonnage, drove her, after her form had been altered, as fast as she was previously driven by engines of double the power, and nearly two knots faster than the same engines drove the smaller vessel before the alteration of her after-body.

Admiralty, August, 1856.

NOTE.—The names of the vessels in the left columns of pages xii. and xiv. apply respectively to the figures of pages xiii. and xv. also, the Tables extending across both pages in each case.—E. J. R.

THE NEW ILLUSTRATED SCIENTIFIC NEWSPAPER.

The Proprietors of the "MECHANICS' MAGAZINE" (established in 1823), have the satisfaction to announce that a New Series of their Journal was commenced last month, in the form of

A WEEKLY SCIENTIFIC NEWSPAPER,

SPLENDIDLY ILLUSTRATED,

UNDER THE EXTENDED TITLE OF

THE MECHANICS' MAGAZINE,

AND JOURNAL OF

Engineering, Agricultural Machinery, Manufactures, and Shipbuilding.

THE SHIPBUILDING DIVISION OF THE MAGAZINE IS NOW UNDER THE EXCLUSIVE CONTROL OF

MR. E. J. REED,

LATE OF HER MAJESTY'S DOCKYARD, PORTSMOUTH.

In this department, the publication of two highly-important series of Articles has been commenced—one on

THE THEORY OF NAVAL ARCHITECTURE;

THE OTHER ON

LAYING-OFF; OR THE GEOMETRY OF SHIPBUILDING.

These Articles are of a very comprehensive nature, and will form, when complete, the most valuable Treatise on Shipbuilding existing in the Language. Other

PAPERS ON NAVAL SCIENCE

APPEAR FREQUENTLY.

EVERY FRIDAY, PRICE FOURPENCE; BY POST, FIVEPENCE.

Annual Subscription, £1 1s. 8d., payable in advance, by Post-office Order, to R. A. BROOMAN, at the Fleet-street Post Office.

ROBERTSON, BROOMAN, & CO.,

THE MECHANICS' MAGAZINE

AND

Journal of Engineering, Agricultural Machinery, Manufactures, and Shipbuilding.

(Registered for transmission abroad.) [EDITED BY R. A. BROOMAN AND E. J. REED.]

VOL. 1.—NO. 1. [NEW SERIES.] LONDON: FRIDAY EVENING, DECEMBER, 31, 1858. PRICE FOURPENCE. BY POST 5d.

THE MUSEUM OF PRACTICAL GEOLOGY, Jermyn-street, is OPEN every day but Friday. Admission free. (42)

LECTURES TO WORKING MEN.—Government School of Mines, Jermyn Street.—The Second Course of Six Lectures on the Models which illustrate the Art of Mining, by WARRINGTON W. SMYTH, M.A., F.R.S., will be commenced on Monday, January 10th, at Eight o'clock. Tickets may be obtained by Working Men only, on Monday, January 3rd, from 10 to 4 o'clock, upon payment of a registration fee of 6d. Each applicant is requested to bring his name, address, and occupation written on a piece of paper, for which the ticket will be exchanged.
27) TRENHAM REEKS, Secretary.

VITRIFIED BLUE BRICKS are delivered at the Nine Elms Station, London, at 80s. per 1,000. —Address, G. H. OGSTON, J. M. Paine's Silica Works, Farnham, Surrey. (36)

ENGINEERS' AND BOILERMAKERS' TOOLS FOR SALE.

A DOUBLE GEARED SELF-ACTING, TURNING, and SCREW-CUTTING LATHE, with travelling saddle and compound slide rest, rack and leading screw, full set of change wheels, and four clawed chuck, height of head stocks, 12in., length of bed, 20ft., with gap to admit an article 4 ft diameter, with top driving gear.

ONE DITTO, height of headstocks, 10 in., length of bed, 12 ft., with gap to admit an article on face plate 3 ft. 4 in. in diameter, with top driving gear.

ONE DITTO, height of headstocks, 8 in., length of bed, 10 ft., with gap in bed to admit an article on face plate 2 ft. 10 in. diameter, with top driving gear.

A STRONG DOUBLE-GEARED SELF-ACTING BORING and DRILLING MACHINE, with table to rise and fall, and with planed bed-plate.

A SINGLE-POWERED DRILLING MACHINE, with table to rise and fall by screw, with driving pulleys and cones complete.

A STRONG PLANING MACHINE; will plane 6 ft. in length × 2 ft 6 in. in width × 2 ft. 6 in. in depth; self-acting in all its cuts.

A STRONG MACHINE FOR MAKING RIVETS will make a ton and a half per day; to work by steam power.

A STRONG MACHINE FOR CUTTING ANGLE IRON, triple geared; wrought by steam power.

A PUNCHING and SHEARING MACHINE; will punch and cut plates ¾-in. thick by steam power.

A PUNCHING and SHEARING MACHINE, will punch and cut plate iron ½-in. thick—to work by power.

A PUNCHING and SHEARING MACHINE; will punch and cut plate iron ¾-in. thick—to work by hand or power.

A PUNCHING and SHEARING MACHINE; will punch and cut plate iron ¼-in. thick—to work by hand.

A SET OF PLATE-BENDING ROLLERS.

A BOLT & NUT-SCREWING MACHINE, with top-driving gear; will screw bolts and nuts from ¼-in. to 1½-in. inclusive.

A SELF-ACTING NUT-SHAPING MACHINE; will cut two sides of a nut at a time from ¼-in. up to 3 in.

The above Machines and Tools are ready for delivery.

Machines and Tools for other purposes made to order.

Address or apply to J. TODD & Co., Kent Iron Works, Bridge-street, Greenwich. (2)

TO BUILDERS.—By Order of the Court of Chancery.—The Trustees of the Bedford Charity are desirous of receiving TENDERS for the ENLARGEMENT of the GRAMMAR SCHOOL; also Tenders for the Erection of a new Preparatory Commercial School, and making a New Road. Plans and specifications of the works required may be seen at the office of Mr. James Horsford, Architect, Bedford. All tenders must be delivered at Mr. Horsford's office, at or before 11 o'clock in the morning of the 24th day of January, 1859. The tenders for the enlargement of the Grammar School must be placed in a sealed cover, and marked "Tender for Enlargement of Grammar School." The tenders for the Preparatory Commercial School must be placed in a sealed cover, and marked "Tender for Building Preparatory Commercial School," and the tenders for making a New Road and other works must be placed in a sealed cover, marked "Tender for Making a new Road and other Works." The Trustees will not be bound to accept the lowest or any Tender. Dated this 20th day of December, 1858.

Signed) JAMES HORSFORD.

MAPLES, MAPLES, and PEARSE, 6 Frederick's-place, Old Jewry, London, Agents for F. W. Pearse, of Bedford, the Solicitor to the said Trustees. (45)

BY HER MAJESTY'S ROYAL LETTERS PATENT.

PATENT SPHERICAL SELF-ADJUSTING BEARINGS, which do not heat in work. The advantages possessed by these Bearings are:—

1st. They are Self-adjusting; and, consequently, can be put down by the most ordinary Mechanic.

2nd. They are not liable to heat, even at high speeds.

3rd. They remain constantly parellel to the Spindle; and, therefore, wear equally all across the Bearing.

4th. They require only a very small quantity of oil.

Engravings and Prices forwarded on application to the Patentees.

WALLIS & HASLAM,

Engineers and Iron Founders, North Hants Iron Works, Basingstoke. (11)

FOR SALE a SISSON ACHROMATIC EQUATORIAL, by Troughton and Simms, London. Object glass 5¼ inches clear aperture, 7ft. 8 inches focal length, polar axis 11ft. 3 inches long by 11 inches square; wheels, brass, 2 feet diameter. The telescope has a micrometer and a large battery of eye-pieces, and a great variety of diaphragams. A very superior 8½ feet Munich Telescope, by Merz and Sons, with or without its stand; tube mahogany object glass, 6¾ inches clear aperture, with micrometer by Dollond, and a large battery of eye-pieces. A heavy Iron Mortar Equatorial, suitable for a tube of from 10 to 15 feet, with declination and right ascension circles; this style of equatorial is remarkable for its stability and freedom from tremor. For particulars apply to Mr. Hew Miller, Ochtertyre, Crieff, N.B. (47)

STOVES.—No Person should order a Stove without first seeing MAGNUS'S CABINET FORMED STOVES, in enamelled slate case. To see is to purchase. They are suitable for halls, churches, public buildings, dining, drawing, sitting, and bedrooms, and are much handsomer and more economical than any other stove extant. —Pimlico Slate Works, 39 and 40 Upper Belgrave-place, S.W. (26)

RAILWAY AXLE-BOXES.

WHEREAS on the 14th December instant, a Verdict was given for the Plaintiff in the action of "Bruff v. Marshall and others," tried before the Lord Chief Justice and a Special Jury at Guildhall, whereby the Patents of the Railway Axle-Box Company were substantiated. NOTICE IS HEREBY GIVEN, that legal proceedings will be instituted against all Manufacturers and others adopting or using any of the Company's Patents, including those of Adams and Richardson, Wrighton, Normanville, Vigurs, McConnell, and Miller, without the Company's express licence in writing. Terms of licenses and other particulars may be obtained from the Manager, Mr. P. M. Parsons, 9 Arthur-street West, London-bridge, E.C.

Dated 22nd December, 1858.

(Signed) E. BENHAM, 18 Essex-street, Strand.

J. HENRY JOHNSON, 47 Lincolns-Inn-Fields.

Joint Solicitors to the Railway Axle-Box Company. (7)

AGRICULTURAL MACHINERY.

ER. AND F. TURNER, IPSWICH, MANUFACTURE PRIZE MILLS for Crushing Corn, Seed, Malt, &c.; Portable Grinding Mills.—Steam Engines, fixed and Portable, from 2-horse power and upwards.—Thrashing Machines.—Chaff Cutters.—Oil Cake Breakers. —Horse Gear.—Saw Table, &c., &c.—all of a superior description, and adapted for Home, Colonial, and Foreign use. Illustrated Price List sent free on application. (31)

J. HOPKINSON & Co., IMPROVERS and MANUFACTURERS of the STEAM-ENGINE INDICATOR of the largest and best description, price £4. 4s., including 7s. 6d. edition of "The Steam Engine explained."

HOPKINSON'S PATENT MERCURIAL STEAM-PRESSURE GUAGES, to indicate up to 30lb., 40s.; to 70lb., 63s.; to 80lb., 100lb., or 120lb., 84s., including quicksilver.

HOPKINSON'S PATENT COMPOUND SAFETY VALVES, for preventing Boiler Explosions.

Apply BRITANNIA WORKS, Huddersfield. (33)

WANTED, BY AN ESTABLISHED MANUFACTURER of SELF-ACTING ENGINEERS' TOOLS, a person to be regularly amongst the trade in London and the South of England soliciting orders. No one need apply who is not thoroughly acquainted with the business and the engineers, &c., of the district, and who cannot give unexceptional reference and security.—Apply by letter, post paid, to A 1, "Mechanics' Magazine" Office, Fleet-street. (25)

BRICK AND TILE WORKS.

TO BE LET, on Lease or otherwise, with Plant and Clayton's Machine complete, and with immediate possession.

The ground is situated on the east side of London; it contains very superior materials for Bricks and Draining Tiles, and a good supply of water without the cost of pumping. Hack-ground and Drying-sheds spacious and well situated. A railway-siding into the ground, with ample accomodation for making three or four millions per annum. For particulars, apply by letter to C. W., 166 Fleet-street, London, E.C. (17)

FIRE BRICKS.—THE FARNHAM INDESTRUCTIBLE SILICIOUS FIRE BRICKS have been greatly REDUCED in PRICE, and will be delivered at the Nine Elms Station, London, at 90s. per 1,000. —Address, G. H. OGSTON, J. M., Paine's Silica Works, Farnham, Surrey. (35)

TO WIRE ROPE MAKERS.—ARCHIBALD SMITH is now prepared to GRANT LICENCES for the use of his PATENT ROPE MACHINERY, guaranteed to work at six times the speed of any other, and to save upwards of fifty per cent. in the cost of making. It is used by the most eminent makers, and was also in the manufacture of the Atlantic Cable.—Apply to 69 Princes-street, Leicester-square, W. (8)

SODA WATER MACHINES. — Before you either purchase, order, or recommend the above, see illustrative and descriptive catalogue, which will be forwarded free on application to S. BARNETT, Engineer, 23 Forston-street, Hoxton, London. A liberal allowance to the trade. (13)

BOILERS, ENGINES, and GEARING FOR SALE, and MADE to ORDER. The patent upright Conical fire-box Boiler is efficient, simple durable, easily understood and managed, very strong, and less liable to be burnt than any other boiler, made of the best materials and workmanship, proved to a high pressure, and requires no brick-work. May be seen in use here. A six-horse power High-pressure Engine, fitted on strong foundation-plate, with wrought-iron crank-shaft, turned fly-wheel, governor and feed pump complete: may be seen in use here. Bright wrought-iron shafting, with couplings, plummer-blocks, pullies, and drums bored and turned. Spur, bevel, and mortise wheels bored, turned, pitched, and trimmed. A quantity, as above, may be seen in use here.—Address, or apply to JOHN TODD and Co., Kent Iron Works, Bridge-street, Greenwich. (46)

TO STEAM SHIP OWNERS, ENGINEERS, AND OTHERS.

How's Patent Steam Engine Counters, can be read at sight.

These Counters register the number of revolutions made by an engine or other mechanism. They may be used for ascertaining the duty of Pumping Engines and Water-wheels; the revolutions on board a steam-vessel; to calculate the slip of the propeller; and in a locomotive to test the slip of the wheels.

How's Patent Salinometer, for Steam Boilers using Salt Water.

By these, the density of the water in the Boiler is at all times accurately shown, and a saving of boiler and fuel is effected. They are adopted by the Admiralty, the Honorable Trinity Corporation, and others. Copies of Testimonials from Messrs. Penn, Messrs. Maudslay, and others, will be forwarded on application.

How's Engine-Room Telegraph, for communicating between Captain and Engineer. Society of Arts Prize Medal, 1855.

This is a Mechanical Telegraph, and by its peculiar construction, error or misunderstanding is rendered impossible. It is now extensively adopted, and gives great satisfaction.

How's Patent Fresh Water Apparatus for Ships' Use.

This apparatus is designed for the distillation of Fresh from Salt Water; and on long voyages, and where the supply of water is scanty, it will be found invaluable. Testimonials may be seen.

Patent Steam Pump and Fire-Engine for Ships' Use.

This Steam-pump occupies but a small space; works perfectly noiselessly, and throws an immense volume of water. An Illustrated Circular of Fresh Water Apparatus and Steam-pump combined, free on application.

How's Patent Machine for Cutting Bolts, Rods, Spindles, Wire, &c.

Simple in construction, inexpensive, occupies but little space, and will not easily get out of order.

A Pamphlet Illustrative of the above, sent free by post, on application to

A. P. HOW, ENGINEER,

81 MARK LANE, LONDON.

EVERY DESCRIPTION OF ENGINEERS' TOOLS, ENGINE ROOM STORES, &c., &c., SUPPLIED.

(38)

SCOTT'S

PATENT GRASS SEED SEPARATOR,

which entirely extracts the Seeds of "COUCH," "TWITCH," "SPEAR," or "HAIR" GRASS, and other impurities from

PERENNIAL AND ITALIAN RYE-GRASS, &c.,

AND

SCOTT'S PATENT CARROT SEED BEARDING

AND

CLOVER AND TREFOIL MILLING OR DRAWING MACHINE,

which effectually removes the beard from Carrot Seed, rendering it fit for sowing with facility by drill or otherwise, and by the separation of abortive or diseased grains vastly increases its vegetative per centage. By a slight modification it is applicable to the other purposes before mentioned.

These Machines were admittedly the most novel, and, at the same time, the most useful and important to the Farmer of any exhibited at the late SMITHFIELD CLUB SHOW.

They may be seen at work at the Establishment of the Manufacturer,

Mr. T. MIDDLETON, Engineer, Southwark.

Communications to be sent to the Patentee, J. SCOTT, 111 Drummond Street, Euston Square, London, N.W. (48.)

THE ROYAL AGRICULTURAL SOCIETY OF ENGLAND'S FIRST PRIZE RE PER.

BURGESS & KEY, PATENTEES AND SOLE MAKERS, 95 NEWGATE STREET, LONDON.

MANUFACTORY, BRENTWOOD, ESSEX.

BURGESS & KEY'S extensive Manufactory is wholly occupied in the Manufacture of

REAPING MACHINES AND GRASS MOWING MACHINES,

upon which they have concentrated their efforts since the year 1851. Their practical experience enables them to produce a Reaping Machine which can be depended on by the Farmer.

Owing to the excessive demand for last season, many orders were left unexecuted. BURGESS & KEY therefore earnestly request that orders for next season (1859) be sent as soon as possible, otherwise they cannot guarantee to deliver in time.

Price £42 10s. Net Cash, at the Works, complete with Conical Screw Divider for long Grain; without the Conical Screw, £40. Extra Knife, £1 5s. If other extras are supplied they are charged for. A man sent to start the Machine, if required, on payment of his expenses.

BURGESS AND KEY'S GRASS-MOWING MACHINE

(ALLEN'S AMERICAN PATENT).

Before introducing this Machine to the English public, BURGESS & KEY determined to fully test its capabilities, and the all-important point—durability. One Machine cut, on the farm of Mr. C. Hall, Havering, Romford, Essex, 83 acres Grass: and the same Machine afterwards cut, on the farm of Mr. Tabrum, Bovis Hall, near Brentwood, Essex, 100 acres Grass, and 20 acres Clover. The work done was declared to be better and lower than the scythe, and at the rate of 1 acre per hour. Orders have been received from both those Gentlemen, and numerous others, for Machines for next Season. Price £30.

BURGESS & KEY'S Manufactory is entirely devoted to REAPING MACHINES and MOWING MACHINES.

95 NEWGATE STREET, LONDON.—MANUFACTORY, BRENTWOOD, ESSEX.

FURTHER PARTICULARS AND CATALOGUES SENT ON APPLICATION. (39)

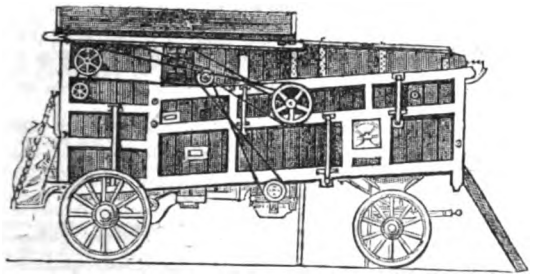
RUSTON, PROCTOR, AND CO.,

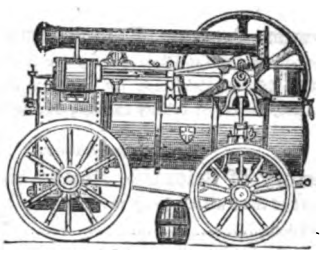
LINCOLN; AND ANCHOR ALLEY, 68 UPPER THAMES STREET, LONDON;

AGRICULTURAL ENGINEERS AND MILLWRIGHTS,



MANUFACTURE

PRIZE PORTABLE and FIXED STEAM ENGINES,
SMITH'S PATENT STEAM PLOUGHS,
PATENT PRIZE COMBINED THRASHING MACHINES, containing R. P. and Co.'s NEW PATENT CORN CLEANER,
SAWING MACHINERY, CIRCULAR and VERTICAL of all Sizes,
MILLS of all Kinds, FIXED and PORTABLE, for Grinding Bones, Flour, Linseed, Mortar, Clay, &c.
PUMPS, CRANES, CRABS, SCREW-JACKS, &c.



Illustrated Catalogues, with full Particulars and Testimonials, may be had by applying as above.

(34)

CLAYTON, SHUTTLEWORTH, AND CO.,

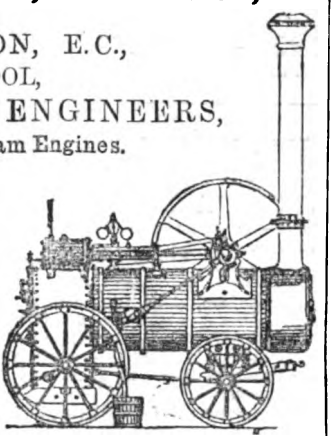
OF LINCOLN,

78 LOMBARD STREET, LONDON, E.C.,

AND 36 DALE STREET, LIVERPOOL,

AGRICULTURAL AND GENERAL ENGINEERS,

And Manufacturers of Portable and Fixed Steam Engines.



Combined Threshing Machines, which dress the corn ready for market at one operation. Grinding Mills, Saw Benches, Pumps for Irrigation and Mining purposes, with all necessary gearing for being driven by steam power. Full particulars and estimates given on application to the above address.

C. S. and Co.'s PORTABLE STEAM ENGINES are adapted for every purpose to which steam-power can be applied. When intended for winding, they are fitted with reversible link motion and winding gear. They are easy of removal, as may be seen by the engraving, and can be set to work immediately on arrival.

C. S. and Co. are now doing an extensive foreign and colonial business, and are prepared to send off engines and machinery of the before-mentioned kinds in a few days from the date of order. They would also call attention to the important *reduction in prices* made for the new year.

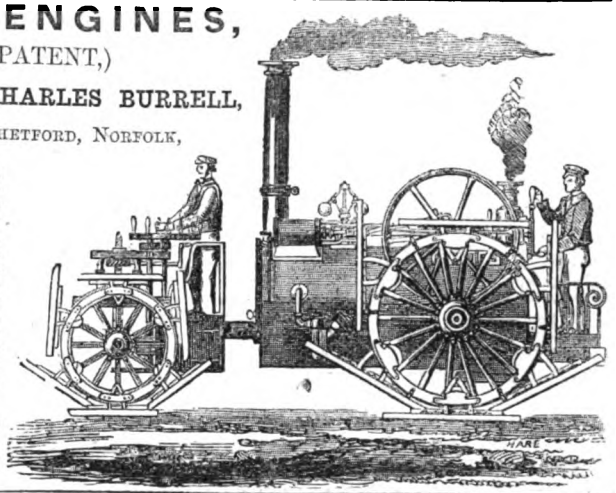
For Exportation.---The above can be obtained through British Merchants, Shippers, and Colonial Agents. (23)

TRACTION ENGINES,

(BOYDELL'S PATENT,)

MANUFACTURED BY CHARLES BURRELL,

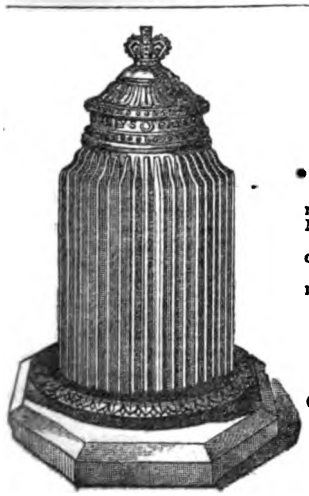
ST. NICHOLAS WORKS, THETFORD, NORFOLK,



And ordered for India, Australia, and South America, may now be seen, complete and in course of construction at the above works. BOYDELL'S TRACTION ENGINES AND ENDLESS RAILWAY will draw heavier loads over good roads than any other traction engine, and on soft and bad roads will draw heavy loads where no other traction engine can move itself. All objection to the wear and tear of these Engines is entirely removed by the use of Charles Burrell's improved patent Wrought Iron Wheels, fitted with Rails and Tyre, as well as all the wearing parts, of Steel.

Apply also to Mr. Hemming, 47 Mark Lane, E.C.

(40.)



THE LONDON

WARMING AND VENTILATING COMPANY,

(LIMITED,)

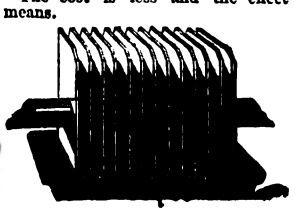
36 GREAT GEORGE STREET, Westminster, S.W.

(MANAGER—Mr. WOODCOCK.)

Churches, Greenhouses, Offices, and Buildings of every description warmed by means of a modification of the plan successfully used during the last five years by Mr. Goldsworthy Gurney in both Houses of Parliament.

Steam, Hot-water, Gas, and in open or enclosed fireplaces, Coal and Coke are equally available for the process.

The cost is less and the effect greater than that of any other known means.



The Horticulturist will find herein an instrument of new and important powers.

The apparatus may be seen in ST. PAUL'S CATHEDRAL, the various offices of the "Department of Science and Art," and in many churches and other buildings.

Particulars and Testimonials forwarded on application.

(12)

TO BRASS-FOUNDERS, ENGINEERS, &c.

THE PATENT PLUMBAGO CRUCIBLE COMPANY having completed the enlargement of their premises, beg to call the attention of all users and shippers of Melting Pots to the great superiority of the PATENT CRUCIBLES, which have been used during the last three years by some of the largest melters in England and abroad. In addition to their capabilities of melting an average of from thirty-five to forty pourings; they are unaffected by change of temperature, never crack, but can be used till worn out, requiring only one annealing for several days' work, and become heated much more rapidly than ordinary pots, effecting thereby a saving of more than fifty per cent. in time, labour, fuel, and waste. The Patent Plumbago Crucible Company also manufacture and import clay crucibles, muffles, portable furnaces, sublimate pans and covers, glass-pots, all descriptions of fire- standing goods, and every requisite for the assayer and dentists. For Lists, Testimonials, &c., apply to Battersea Works, London, &c. (43

Important to every man who keeps

THORLEY'S FOOD FOR CATTLE,

77, NEWGATE STREET, LONDON

Beware of spurious imitations. (49)

ARTESIAN WELLS, BORING TOOLS, PUMPS, &c. Engineers, Architects, Surveyors, Builders or others requiring a good supply of Water may have any quantity procured by W. SPELLER, 14 York-street, Blackfriars'-road, London, where may be had any quantity of Tools for Sinking or Boring, from 2 to 20 inches diameter, and from 100 to 2,000 feet depth; also Men and Tools to bore for Railroads, Minerals, &c., in any part of the world. Boring Tools and suitable Pipes for exportation, with full instructions for their use.

Builders, Contractors, Brickmakers, Barge and Ship Builders, and others, can be supplied with Wrought or Cast Iron Pumps, Double or Single, for excavation of Deep Wells, from 3 to 14 inches in the bore, and from 6 to 130 feet in length, to work by Hand or Steam Power.

Hot-water Apparatus for Conservatories, &c., on the most economical and improved principles.

Also Manufactory for Captain John Grant's much improved Cooking Apparatus. (44)

KIRBY AND SPENCE'S ENTOMOLOGY.
EIGHTH THOUSAND OF THE SEVENTH AND CHEAPER EDITION.
Just published, in One closely-printed Volume of 600 pages, crown 8vo, price 5s. cloth,

INTRODUCTION to ENTOMOLOGY; or Elements of the Natural History of Insects; comprising an Account of Noxious and Useful Insects; of their Metamorphoses, Food, Stratagems, Societies, Motions, Hybernation, Instinct, &c. By WILLIAM KIRBY, M.A., F.R.S., F.L.S., Rector of Barham; and WILLIAM SPENCE, Esq., F.R.S., F.L.S. Seventh Edition. (8th Thousand), with an Appendix, relative to the Origin and Progress of the Work.

"Let no man think he knows how to enjoy the country who has not studied the volumes of Kirby and Spence."
QUARTERLY REVIEW (*The Honey Bee*).

"No work in the English language, we believe, has done more than Kirby and Spence's learned & popular Introduction to spread the taste for Natural History at home.....The book is, indeed, a marvel of cheapness,—considerably more than 600 closely-printed octavo pages for five shillings.....To our readers old and young,—parents, children, teachers, respectively,—we say, 'buy and read;' enjoy, verify, and enlarge, by the use of your own eyes and faculties, the curious details in rural economy, animal biography, & mental philosophy, amassed with so much study and personal observation, and digested with equal taste and judgment by the learned authors."
NATURAL HISTORY REVIEW.

London: LONGMAN, BROWN, and Co., Paternoster-row. (28)

CATALOGUE of BOOKS with Valuable Importations from Austria, Bavaria, France, and Italy, on the subjects of Architecture, Ornament, and Photography; together with Works on Civil, Mechanical, Military, and Naval Engineering; being the publications of, and consignments to, JOHN WEALE, No. 59 High Holborn, London. Price 6d.; if by post, 7d. (6)

Price 10s. 6d. handsomely bound, gilt edges,

THE UNIVERSAL ATLAS; containing 400 coloured Maps, Diagrams, and Illustrations of Astronomy, Physical Geography, Geology, the Vegetable Kingdom, &c., with popular description. A most interesting and instructive, as well as elegant work for a present.
London: JAMES REYNOLDS, 174 Strand. (41)

RANSOME'S PATENT IMPERISHABLE SILICIOUS STONE.—Chimneypieces, Balustrades, Capitals, Trusses, Terminals, Fountains, and Vases; also, Enamelled Stone Chimneypieces, of great beauty and novelty, at reduced prices. Monumental or Mural Memorials, Grave Stones, Space Markers, and Indicators for Cemeteries, &c., of every description, at the lowest price.

RANSOME'S PATENTED PROCESS FOR PRESERVING STONE.—Invaluable in its application to Public Edifices and Private Residences. By this process the softest and most friable stone can be rendered impervious and imperishable, and decay at once arrested and prevented.

RANSOME'S PATENT STONE FILTERS FILTERING SLABS.—Manufactured for every Private or Domestic purpose, for Manufactories, Public Companies, Shipping, &c. Several hundred thousand gallons of water are filtered daily by Ransome's Patent Stone Filtering Slabs, for the town of Southampton. They have also been adopted by the Admiralty, the Board of Ordnance, the Colonial Land and Emigration Commissioners, and other Public Bodies for several years; also in the City of Rotterdam, with the most perfect success.

For particulars, specimens, illustrations, and agencies, apply to

Mr. FREDERICK RANSOME,
WHITEHALL WHARF, CANNON ROW,
WESTMINSTER;
OR PATENT STONE WORKS, IPSWICH.
A liberal discount allowed to the Trade or to Shippers. (14)

A NEW DISCOVERY IN WASHING HOUSEHOLD LINEN.

NO FAMILY SHOULD BE WITHOUT HANCOCK'S UNIVERSAL WASHING MACHINE. It effectually cleanses the Crevices of Baby-linen, Collars, Wristbands, &c., without the possibility of injuring the Linen or Collars. Received 500 Testimonials.

PRICES.

No. 2 Washes 9 Shirts in from 8 to 10 minutes; or 4 Sheets in 5 minutes	£5 5 0
No. 3 Washes 12 Shirts in from 8 to 10 minutes; or 6 Sheets in 5 minutes	7 11 0
No. 4 Washes 18 Shirts in from 8 to 10 minutes; or 12 Sheets in 5 minutes	12 12 0

And all other Articles in proportion.
J. L. HANCOCK, Sole Manufacturer and Patentee, 62 Pentonville-road, London. (3)

CHUBB'S LOCKS, FIREPROOF SAFES, CASH AND DEED BOXES.
Complete lists of sizes and prices may be had on application.

NOW READY, PRICE TWO SHILLINGS AND SIXPENCE.

THE

LITERARY AND EDUCATIONAL YEAR-BOOK

FOR 1859.

THE LITERARY and EDUCATIONAL YEAR-BOOK for 1859 contains with a variety of other useful and interesting information :—

A List of all the New Books published during the present year, with the name of author, price, size, binding, and publisher of each book; also a List of the London Publishers, with their addresses.

Lists of the principal American and Foreign Books published during the present year, with the price, and name of publisher of each book.

The Titles of the Articles which appeared in the Quarterly Reviews during 1858.

Lists of Works printed by order of the Commissioners of Patents and Inventions, including Chronological Indices and Classified Abridgments of all Specifications of Patented Inventions, from the earliest enrolled to those published under the Act of 1852; and the names and addresses of the Free Libraries and Public Institutions, where such Works, including upwards of 1,000 volumes, may be daily consulted.

A List of all the Prints published during 1858, with the name of engraver, price, size, and publisher of each.

A List of all the new Maps, published during 1858, stating size, price, and publisher of each.

Lists of all the Metropolitan and Provincial Newspapers, stating where each paper is published, when it was established, its peculiar politics or principles, day of publication, and price.

The names and addresses of all the principal Newspapers in all the great towns and cities of the Continent; also those published in the British Colonies and the United States of America.

Lists of all the Weekly, Monthly, and Quarterly Publications of the Metropolis and the Provinces, stating when and where each is published, and price.

The Learned, Philosophic and Artistic Societies of the Metropolis, stating the nature and object of each Society, with the names of the Officers of each, the papers read before each in 1858, and all the necessary information about conditions of membership, entrance fees and annual subscriptions, days of meetings, &c.

The Public Metropolitan Libraries and Museums, and Lists of the Metropolitan and Provincial Schools of Art and Science, with the names of the principal promoters and teachers of each school.

A List of the Mechanics' and Literary Institutions, Working Men's Colleges, and Mutual Improvement Societies; also a List of the Young Men's Christian Associations of the country.

Book-Hawking Societies, Itinerating Libraries, and information about County Associations, Evening Classes, &c.

The Universities of the country, with the names of the Professors, Masters, Tutors, Examiners, Moderators, Officers, &c.; and the principal Grammar Schools and Dissenting Colleges, with the names of Head Masters, Tutors, &c.

The names of all who graduated at the London University during 1858, arranged in alphabetical order under their respective divisions.

Public Libraries, News Rooms, Printing Societies, Metropolitan Clubs, Philosophical Institutions, &c.

All the Successful Candidates of the Middle-Class Examination for 1858, with the Name, Address, Age, Place of Examination, and Local School of each Candidate. The Names are arranged according to merit, and in alphabetical order, under separate divisions. Also all the requisite Information, including Regulations and Particulars, for the Final Examination in June, 1859.

All the Prizes and First and Second Class Certificates awarded at the Final Examination of the Society of Arts Union of Institutes for 1858, stating Name, Age, Profession, or Trade, and Local Institution of each Candidate. The Names of the Successful Candidates are arranged according to Order of Merit, and classified under different divisions. Also a List of the Subjects for Final Examinations in 1859, including Regulations for Candidates, with the names of Books of Reference recommended by the Council. Also the Names of the Examiners for 1859, and the Prizes offered.

A List of the Names of the first 216 Apprentices of the Royal Dockyards, arranged in Order of Merit, as determined by the Examinations of the Inspectors.

The paid and gratuitous Lecturers in the country, stating the address and general subject or subjects treated of by each person.

An Obituary of Eminent Persons of all Countries for 1858.

Literary, Artistic, and Educational Memoranda, in which all noteworthy information referring to Books, Pictures, Autographs, &c., for 1858 is recorded.

THE LITERARY and EDUCATIONAL YEAR-BOOK for 1859 also contains a variety of other information on the Copyright and International Copyright Laws, Statistics of Public Libraries, Hints on the best mode of establishing and sustaining Educational Institutions for the People, Female Education, Hints on Printing, Publishing, Advertising, &c.

THE LITERARY and EDUCATIONAL YEAR-BOOK for 1859 contains upwards of 25,000 Facts appertaining to Literature, Art, Science, and Education.

LONDON: KENT & CO., PATERNOSTER ROW, AND FLEET STREET.

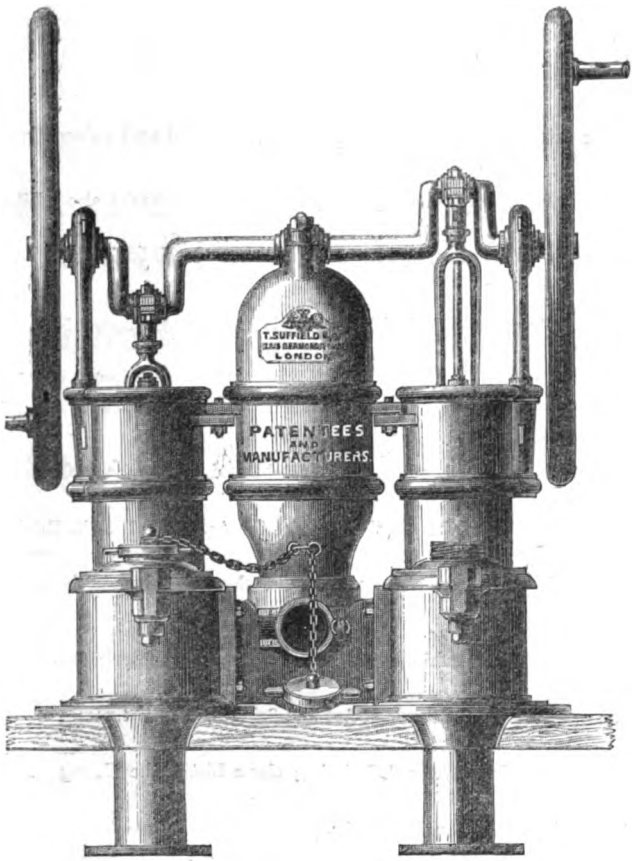
T. SUFFIELD AND CO.

Call the particular attention of

SHIP-OWNERS, SHIP-BUILDERS, AND COMMANDERS OF STEAM AND SAILING VESSELS,

to the Simple and Efficient Arrangements of their

PATENT PUMPS.



Ships' Pumps

AND

Fire Engines,

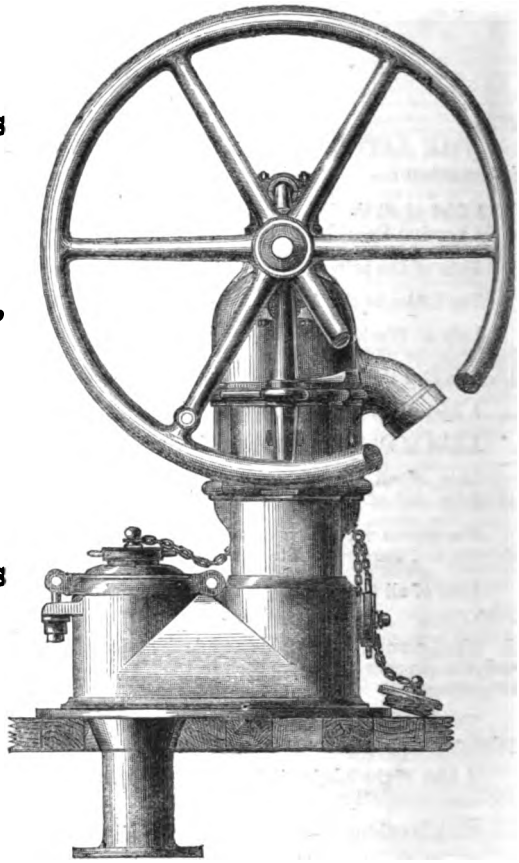
Fixed and Portable.

WITH

Patent Valves

AND OTHER

Improvements.



These Pumps are free from that liability to choke which is common to other Pumps, and their Working Parts are not susceptible of derangement either from wear or from being long out of use. They pass entirely through them, with ease, any substance that may enter the Suction Pipes. The Novelties in these Pumps are their adaptation to the varied duties of Ships' Pumps; the facilities they afford for Cleansing the Suction Pipes, and for Sounding or Examining the Valves; the readiness with which they may be used for Ventilating the Bilge, or for acting as a Syphon either for Watering the Ship, or for extinguishing Accidental Fires on board; the rapidity with which they can be converted into Fire Pumps, or be applied to the Washing of Decks; and their capability of Pumping from Several Compartments.

T. SUFFIELD AND CO.

Also respectfully solicit the attention of STEAM SHIP BUILDERS and OWNERS to their Large and Varied STOCK of

ASSORTED STORES FOR MARINE PURPOSES.

They keep a Large Stock of Goods, of their own Manufacture and from the Best Makers, constantly on view; so that by a visit to their Works or Depôt, much valuable time may be saved by Managers, Engineers, and other Gentlemen who may require such Stores, together with a further saving in the cost of such Articles.

DEPOT, 116 FENCHURCH STREET, E.,

(OPPOSITE MARK LANE.)

4 ,,	3 ,, 6 ,,	3 3
2½ ,,	3 ,, 6 ,,	3 3
2½ in. short, with 15 feet of Lead Pipe attached, ready for fixing		2 14
2½ in. long. do. do.		2 18

PATENT BRASS LIFT AND FORCE PUMP, on Plank, for House purposes, supply of Cisterns, &c.

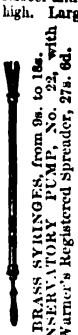
	£ s.
2½ inch	6 0
3 ,,	7 5
3½ ,,	8 0

A lighter Pump of 3 inches diameter, can be supplied if required 5 15

IMPROVED LIQUID MANURE, OR GENERAL PORTABLE PUMP.

These Pumps are fitted with J. Warner and Son's Patent Bucket and Sucker, and cannot clog in action. The Barrel is of Galvanized Iron, not likely to corrode, and can be raised or lowered at pleasure. The legs will fold together, and the whole may be carried on shoulder to any pond or tank required.

4½ in. Liquid Manure Pumps, with legs, £3 3s.; 1¾ in. Gutta Percha Suction Pipe, 1s. 11d. per foot; 2 in. Flexible Rubber and Canvass Suction Pipe, on Wires, 3s. 3d. per foot. The Barrel is 27½ inches long, and the legs are 5 feet high. Larger sizes of the above if required.



BRASS SYRINGES, from 9s. to 18s.
CONSERVATORY PUMP, No. 22½, with Warner's Registered Spreader, 27s. 6d.

Galvanized Iron Tub GARDEN ENGINE, with Warner's Registered Spreader, is strongly recommended for durability and low price, viz., £2 19s., to hold Ten Gallons. Larger sizes, in either wood or iron.

WARNER'S SWING WATER-BARROW.
(To hold Thirty Gallons), £3 3s.,

is intended for all large Establishments where much watering is done by the watering-pot. By its use much time and labour of the Gardener are saved, particularly where the Tank, Pond, or Pump is at a distance from the garden.

MUSICAL SHEEP BELLS, with Straps, in sets of 6, 19s.; ditto, in sets of 8, 25s.; ditto, in sets of 12, 38s.

WARNER'S CATTLE AND SHEEP BELLS, in sets of 6, with Straps, 13s. per set.

Bells for Churches, Chapels, Colleges, Schools, Turret Clocks, &c., cast for any size, note, or weight, singly or in peals. Tuned by machinery. Stocked and wheeled ready for fixing. Old Bells re-cast or taken in exchange.

The great 16-ton Bell, for the Houses of Parliament, was made by JOHN WARNER and SONS, 1856, under their Patent.

May be obtained of any Ironmonger or Plumber, in town and Country; or of the Patentees and Manufacturers, as above. (30)

Pumping Machinery.

GWYNNE AND Co., Engineers, London, manufacture and supply the following Machinery, of the most approved construction and with all the latest improvements :—Portable and Fixed Steam-Engines and Boilers of every description ; Waterwheels, Windmills, Horse and Hand-power Machines ; Pumping Machinery for the Supply of Towns, Cities, and Districts, and for the Irrigation of Coffee, Cotton, Indigo, Sugar-cane, and Rice Estates, for pumping out Coffer-dams, Canals, Dry Docks, Reservoirs, &c. They also manufacture and supply the Pumping and other Machinery for Paper, Pulp, and Fulling Mills, Breweries, Distilleries, Tanneries, Starch Works, Bleaching, Dyeing, and Calico Printing Works, Chemical Works, Silk, Cotton, and Flax Mills, and Manufactories in general. All Letters not paid will be refused. Illustrated Price Lists forwarded on receipt of Six Postage Stamps.—GWYNNE AND Co., Hydraulic and Mechanical Engineers, Essex-wharf, Strand, London.

For Exportation.—The above can be obtained through British Merchants, Shippers, and Colonial Agents. (24)

CAST STEEL SHOVELS AND SPADES,

HAY, MANURE, AND DIGGING FORKS.

RECOMMENDED FOR THEIR EXTREME LIGHTNESS AND DURABILITY.

MANUFACTURED BY

SPEAR AND JACKSON,

ETNA WORKS, SHEFFIELD.

To be had of all Implement Dealers and Ironmongers throughout the Country, and Wholesale (only) of the Manufacturers. (22

IMPORTANT TO MANUFACTURERS, MILL OWNERS, &c.

GUTTA PERCHA MILL BANDS.

THE GUTTA PERCHA COMPANY beg to state that the increasing demand for the Gutta Percha Strapping for Driving-bands, Lathe-straps, &c., fully justifies the strong recommendations they have everywhere received.

Their durability and strength—permanent contractability and uniformity of substance—their non-susceptibility of injury from contact with oils, grease, acids, alkalies, or water—and the facility with which the only joint required can be made in bands of from 200 to 300 feet long—render them superior to leather for almost all working purposes, and decidedly more economical.

TESTIMONIALS.

IMPORTANT ANNUAL SAVING.

From TRUMAN, HANBURY, BUXTON, & Co., Brewery, London.

"In reply to your inquiry, we have much pleasure in bearing our testimony to the advantages, both as regards economy and saving of time, effected by the use of your Patent Gutta Percha Bands in lieu of Leather Straps. The stoppage of one portion of our works through the failing of the leather strap used to be of daily occurrence—but with this annoyance we are now never troubled. We have had these straps in operation for nearly three years, and are assured by our Engineer that *they effect a saving to us of at least* THIRTY POUNDS *a year*."

From JAMES ABERNETHY & Co., Fury Hill Foundry, Aberdeen.

"We have now had Gutta Percha Bands working here *for three years*. One of them has been driving the fan blast for our smith's shop for all that time, and for anything we see, may drive it as long again. The speed of the fan is but 1,200 per minute. We have used them with complete satisfaction, driving circular saws, and in some cases where leather bands would have been quite inapplicable from damp. We have uniformly endeavoured to have the drums and pulleys so proportioned to the strain, as that there is no chance of the band slipping; and with this precaution, and taking care in using *cross bands that they do not rub*, we are quite satisfied that they are superior in every respect to leather—stronger at the same weight, and keeping quite straight in working—requiring no lacings, and very seldom any repairs."

WATER POISONED BY LEADEN PIPES.

The above engraving represents accurately a section of a leaden pipe, which was employed for a short time in conveying water from a well on the grounds of Mr. Dick, of Bonchurch, Isle of Wight.

POISONED WATER PREVENTABLE

BY THE USE OF GUTTA PERCHA TUBING.

The Gutta Percha Company have been favoured with the following letter,

From Dr. MURRAY, Hull.

"It is impossible to conceive of anything more injurious or destructive to the health of the community than the use of *leaden pipes* for the conveyance of water. The poisonous salts of lead thereby communicated are most insidious and subtle. I hail with gratitude the substitution of Gutta Percha Tubing. I have had the leaden pipe of my own house removed, and its place supplied with one of Gutta Percha Tubing. Nothing can be better. I have also recommended it to others, who have adopted the expedient."

A variety of Gutta Percha Articles, such as Mill Bands, Tubing, Sheet, Soles, Pump Buckets, Bosses, Union Joints, Bottles, Bowls, Flasks, Curtain and Cornice Rings, Solid Frames, Galvanic Batteries, &c., &c.

MANUFACTURED BY THE

Gutta Percha Company, Patentees,

18 WHARF ROAD, CITY ROAD, LONDON,

AND SOLD BY THEIR

WHOLESALE DEALERS IN TOWN AND COUNTRY. (29.)

By Her Majesty's Royal Letters Patent.

HART'S

PATENT GAS ECONOMIZING BURNER,

AND ILLUMINATING POWER DIFFUSER,

ONE SENT ON RECEIPT OF THIRTY POSTAGE STAMPS.

DEPOT, 69 FLEET STREET, LONDON.

No. 4.

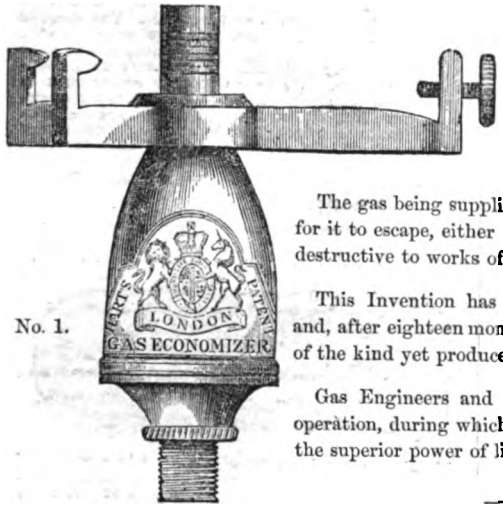
This very complete and simple apparatus is the greatest desideratum of the age to all gas consumers. It can be applied to any Gas Chandelier Stand or Bracket in a few moments by the most inexperienced hand. It is impossible for it to get out of repair, and its construction is so simple that it cannot be deranged in any way. The saving effected—from 5 to 35 per cent.—will defray its own cost in from one to three months.

The evil which necessarily arises from the great variation of pressure in the mains, is remedied by means of the Gas Economizing Burner producing an illuminating power far superior to any other (varying in degree from 10 to 50 per cent., as proved by experiments made with photometer); the effectual working will be guaranteed for ten years. This is produced by means of a simple apparatus fitted within the Economizer, which effectually checks the undue pressure, and so allows the gas to permeate with its natural velocity; this being attained, all noises caused by overdue pressure are obviated, and, at the same time, any flickering prevented.

No. 3.

PRICE

2s. EACH.

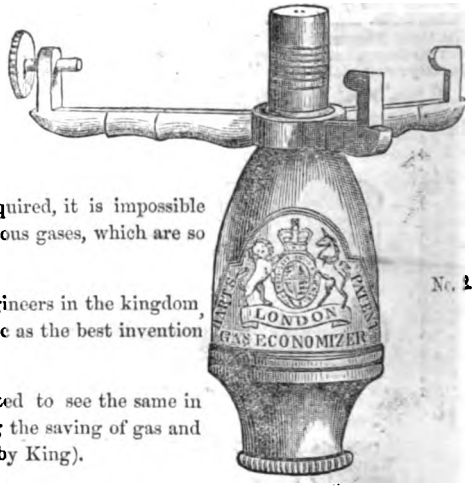


No. 1.

The gas being supplied from the burner at the exact velocity required, it is impossible for it to escape, either as smoke or other invisible but more noxious gases, which are so destructive to works of art, and also injurious to health.

This Invention has been tested by the most eminent Gas Engineers in the kingdom, and, after eighteen months' severe trial, is brought before the public as the best invention of the kind yet produced, and by far the cheapest.

Gas Engineers and other scientific men are respectfully invited to see the same in operation, during which time thorough tests will be made, proving the saving of gas and the superior power of light (by Bunsen's Photometer as improved by King).



No. 2.

SOLD BY ALL RESPECTABLE GAS FITTERS AND IRONMONGERS

IN THE UNITED KINGDOM,

AND BY THE PATENTEE AT THE ABOVE ADDRESS.

NO REGULATOR OF ANY KIND REQUIRED,

NEITHER WILL ANY REGULATOR DIFFUSE THE ILLUMINATING POWER, BUT, ON THE CONTRARY, CHECK ITS DEVELOPMENT.

TESTIMONIALS.

POLYTECHNIC CHEMICAL SCHOOL, LONDON.

This is to certify that I have carefully conducted a series of experiments with various gas burners in present use, and find that "Hart's Patent Economizing Gas Burner" is the most economical of all, producing, when compared with others, a saving of 40 per cent.

(Signed this 14th Dec., 1858.)

EDW. V. GARDNER,
Professor of Chemistry, &c., &c., &c.

809 Regent Street.

I have Mr. Hart's Gas Economizing Burner fitted to every branch in my house, and can speak in the highest terms of its success. The light is perfectly steady, and the flame more brilliant, with perfect combustion, so that the air is by no means oppressive as formerly; the ceilings have no chance of being blackened, and the gilt frames and furniture cannot now, as before, be injured. I most warmly recommend their adoption.

(Signed)

WM. V. PETTIGREW, M.D., Hon. F.R.C.S., Eng.

7 Chester St., Grosvenor Place, Pimlico, Nov. 3, 1858.

Published by RICHARD ARCHIBALD BROOMAN, at the MECHANICS' MAGAZINE Office, 166 Fleet-street, in the Parish of St. Dunstan's-in-the-West, in the County of Middlesex; and printed by JAMES JUDD and HENRY ALEXANDER GLASS, of 34 Holford-square, Pentonville, in the County of Middlesex, at their Office, 38A New Bridge-street, in the Parish of St. Anne's Blackfriars, in the City of London—Friday, December 31, 1858.

THE MUSEUM OF PRACTICAL GEOLOGY, Jermyn-street, is OPEN every day but Friday. Admission free. (42)

LECTURES TO WORKING MEN.—Government School of Mines, Jermyn Street.—The Second Course of Six Lectures on the Models which illustrate the Art of Mining, by WARRINGTON W. SMYTH, M.A., F.R.S., will be commenced on Monday, January 10th, at Eight o'clock. Tickets may be obtained by Working Men only, on Monday, January 3rd, from 10 to 4 o'clock, upon payment of a registration fee of 6d. Each applicant is requested to bring his name, address, and occupation written on a piece of paper, for which the ticket will be exchanged.
(27) TRENHAM REEKS, Secretary.

ROYAL INSTITUTION of GREAT BRITAIN, Albermarle-street.
The WEEKLY EVENING MEETINGS of the Members of the Royal Institution will commence for the season on Friday, the 28th of January, 1859, at half-past 8 o'clock, and will be continued on each succeeding Friday evening, at the same hour.
Arrangement of the Lectures before Easter.
Twelve Lectures on Fossil Mammals—By RICHARD OWEN, Esq., D.C.L., F.R.S., Fullerian Professor of Physiology, R.I. To commence on Tuesday, January 25, at 3 o'clock; and to be continued on each succeeding Tuesday, at the same hour.
Twelve Lectures on the Force of Gravity—By JOHN TYNDALL, Esq., F.R.S., Professor of Natural Philosophy, R.I. To commence on Thursday, January 27, at 3 o'clock; and to be continued on each succeeding Thursday, at the same hour.
Nine Lectures on Organic Chemistry—By W. A. MILLER, M.D., F.R.S., Professor of Chemistry at King's College, London. To commence on Saturday, January 29, at 3 o'clock; and to be continued on each succeeding Saturday, at the same hour.
Subscribers to the Lectures are admitted on payment of two guineas for the season, or one guinea for a single course. A Syllabus may be obtained at the Royal Institution. J. BARLOW, M.A., V.P., and Sec. R.I.
Dec. 25, 1858. (64)

TO PUBLIC COMPANIES, Carriage Builders, Pianoforte Makers, and others. Mr. Lerew is directed to LET or SELL, with immediate possession, those extensive MANUFACTURING PREMISES, near the Goods Station of the London and North-Western Railway, known as the Camden Works, elegibly situate at Hawley-crescent, Camden-town, on the banks of the Regent's Canal, with good lay-by, and excellent wharf; consisting of a spacious and lofty fire-proof hall, 120 ft. long by 40 ft. wide, two engine-houses, and stacks of very extensive workshops and store-rooms, admirably arranged and spacious airy offices. These most substantial and elegible works will be found worthy of the inspection of any manufacturers of extent. For further particulars and orders to view apply to Mr. Lerew, auctioneer, Cardington-street, Hampstead-road, near the Euston Station, N.W. (65

STEAM ENGINES FOR SALE.
PORTABLE STEAM ENGINES, from 6 to 12 horse power,
STATIONARY STEAM ENGINES, from 4 to 50 horse power,
TUBULAR BOILERS, from 4 to 50 horse power,
CORNISH BOILERS, from 4 to 50 horse power,
Are in hand, and can be despatched on eight days' notice. Prices moderate. Workmanship and Material of the best description.
Apply to R. THORNTON & Co., St. Leonard's Iron Works, Edinburgh. (60)

ENGINEERS' MACHINES AND TOOLS—
READY AND NEARLY READY FOR DELIVERY.—For Planing, Shaping, Drilling, Boring, Turning, Slotting, Bolt-screwing, Nut-shaping, Rivet and Spike-making, Boilerplate Bending, Punching and Shearing. Machines and Tools for other purposes made to order. Apply to JOHN TODD and Co., Kent Iron Works, Bridge-street, Greenwich. (71)

HART & SON, MALLEABLE IRON-FOUNDERS, 4 Vine-street, York-road, Lambeth.
Orders for Malleable Iron Castings executed within a week. (77)

TO MARINE ENGINEERS, OR SHIP-BUILDERS.
THE PROPRIETOR of a VALUABLE PATENT for Double-expansive Marine Engines (by which great economy of space and fuel are obtained) is desirous of entering into arrangements with a respectable firm for the construction of the same. An adequate portion of the patent-right would be assigned by the advertiser to any firm taking the matter up; and he would render all assistance in his power, either in London or elsewhere, amongst ship-owners (to many of whom he is well known), in obtaining contracts, &c. Unexceptionable references given. Address C. E., MECHANICS' MAGAZINE Office, 166, Fleet-street. (76)

MARINE ENGINE DRAUGHTSMAN.
WANTED, the Assistance of a THOROUGHLY COMPETENT MARINE ENGINE DRAUGHTSMAN, to prepare finished and working drawings of a newly patented marine engine. The drawings may be executed either at the applicant's own residence or at the offices of the advertiser. None need apply who are not well accustomed to designing marine engines, and thoroughly acquainted with their details as carried out by the best makers. Applications stating where employed, and the rate of remuneration required, to be addressed to X. Y. Z., MECHANICS' MAGAZINE Office, 166 Fleet-street. (74)

GLADSTONE & Co., CONTRACTORS and ENGINEERS.
2 John-Street, Minories, London, E.C.,
Are prepared to ESTIMATE FOR and CONSTRUCT BRIDGES, PIERS, JETTIES, &c., in Iron, Wood, or Stone. Also to supply Cranes, Girders, Turntables, and Railway Work and Plant generally. (81)

PARTNERSHIP in an Iron Manufactory in the Midland Counties. The services of any young man of business habits and experience, and having the command of £1,000, can be made available. The business is a very old one, and will give each partner from £400 to £500 per annum, Apply to Messrs. Lara & Walters, professional agents, 6 Pump-court, Middle Temple, E.C. (67)

ENGINEERING AND MECHANICAL DRAWING CLASSES.—Instruction given in Engineering and Mechanical Drawing, comprising the preparation of plans, elevations, and sections of marine and locomotive engines, with the detail and working drawings; also the method of delineating screws, bevel wheels, &c.; orthographical projection, and tinting, shading, and colouring taught.—For prospectuses of the Day and Evening Classes apply to Mr. T. J. HILL, at the offices, 15, Old-street, City-road. 73)

To Carpet Manufacturers and others.—In re Pardoe, Hoomans, and Pardoe, Kidderminster.
MESSRS. FULLER and HORSEY are instructed to SELL by AUCTION, at the Works Kidderminster, on Tuesday, February 1, and following days, at 11 for 12 precisely, in lots, the costly modern MACHINERY and UTENSILS of the CARPET MANUFACTORY; including 126 power looms (Crossley's patent, Halifax), 6 four-quarter for velvet or tapestry, 36 three-quarter for velvet pile, and 84 three-quarter for tapestry, wool-dyeing machine with 3 steam cylinders, a wool devil, card grinding machine, 1000 beams, 9 first-class carding engines, 6 drawing frames, 2 knot frames, 62 printing cylinders from 12 feet to 36 feet diameter, 15 starching frames, capable of starching to four-quarter wide, starch boilers, 4 pairs of washing rollers, whizzing machine, 2 Hoyle's centrifugal drying machines, willowing machine, 2 Gwynne's centrifugal pumps, 2 very superior steam drying machines, with 11 and 12 cylinders respectively 78 inches wide, by Mather, 4 Crossley's setting machines, 37 setting frames, with reeds and creels complete, 6 reeding-in machines, Mitchell's sewing machine, measuring and rolling machine, 5 double yarn winding machines, 36 bobbins each; 2 reeling machines, 50,000 bobbins; 2 linen yarn winding machines, 18 swifts each; 4 quill winding machines, fittings and racks in drying stoves; 4 costly wrought-iron steam chests for yarn, 10 trucks, iron tramway; colour plant, consisting of copper evaporating pan with false bottom; 2 copper extractors with evaporators (Bourras' patent), copper logwood boiler, 8 copper jacket steam pans, 1 open copper boiler, 2 copper steam boiling pans, 2 leaded cisterns, copper cochineal boiler, new orchil back, fittings in laboratory, wrough-iron orchil liquor cisterns, 1000 colour boxes, fittings in colour room, 200 seed trays, 5 soaking vats, two lined with lead, sifting or screening machine, 6 warping machines with creels, 3 four-quarter carpet shearing machines, 2 yarn winding machines, 16 swifts each; oblong oil tank, 3 orchil backs with covers, steam coils and pipes, force and lift pumps, 3-ton weighbridge, weighing machines and weights, an excellent 16-horse power condensing steam beam engine, a donkey pumping engine, 3 double-flue steam boilers, each 20 feet long, 7 feet diameter, fixed in 1857; wrought-iron expansion chest, wrought-iron water heater, 5000 feet cast and wrought-iron steam pipe up to 12 inches diameter; 3000 feet turned wrought-iron shafting with hangers, plummer blocks and couplings; 500 turned riggers and pulleys, 5000 feet leather and patent bands, 50 pair geared wheels, 1000 feet cast and wrought-iron water pipe, 10,000 feet gas pipe, all the burners and fittings; the fittings in millwrights', carpenters', and smiths' shops, 2 forges and bellows, anvils, top and bottom swages, vices and benches, heavy turning and boring lathe, four turning lathes (one self-acting), drilling machine, grind-stone, 5 tons useful machinery, castings, 5 tons rod and bar iron, circular saw bench, shuttle-making machine, fly press, eight-day clock, metal dinner-bell, hand trucks, baskets, and numerous other effects. To be viewed (the machinery in motion) three days prior to the sale. Catalogues (at 1s. each, without which no person will be admitted) may be had of Messrs. Druce and Sons, solicitors, Billiter-square, London, E.C.: of William Brinton, Esq., solicitor, Kidderminster; of Messrs. Robinson, solicitors, Dudley; and of Messrs. Fuller and Horsey, Billiter-street, London, E.C. (62)

Weekly sales by Auction, twice a day.—Notice.
MESSRS. BOOTH and Co., at the request of friends and customers, respectfully announce that in future their monthly SALE of WOOD and IRON GOODS, building materials, shop and other fittings, tools, implements, stock stoves, &c., of all kinds connected with mechanical trades, will be held weekly, on every Tuesday, at 1 for 2 o'clock, at the Builder's Sale Grounds, 23 and 24 Marylebone-road, W. And further notice, that evening sales are in preparation, to be held on the same dates for the sales of tools. Persons wishing to send in goods will be supplied with lotting forms, terms, and full information gratis, on application or by post with the builders' sales, plan, and catalogue of sale for two stamps. Direct to Booth and Co., at the premises as above, or the Building Trades' Registry office, 13, Eastcheap, London, E.C. (63)

J. HOPKINSON & Co., IMPROVERS and MANUFACTURERS of the STEAM-ENGINE INDICATOR of the largest and best description, price £4. 4s., including 7s. 6d. edition of "The Steam Engine explained."
HOPKINSON'S PATENT MERCURIAL STEAM-PRESSURE GUAGES, to indicate up to 30lb., 40s.; to 70lb., 63s.; to 80lb., 100lb., or 120lb., 84s., including quicksilver.
HOPKINSON'S PATENT COMPOUND SAFETY VALVES, for preventing Boiler Explosions.
Apply BRITANNIA WORKS, Huddersfield. (23)

TO STEAM SHIP OWNERS, ENGINEERS, AND OTHERS.

How's Patent Steam Engine Counters, can be read at sight.

These Counters register the number of revolutions made by an engine or other mechanism. They may be used for ascertaining the duty of Pumping Engines and Water-wheels; the revolutions on board a steam-vessel; to calculate the slip of the propeller; and in a locomotive to test the slip of the wheels.

How's Patent Salinometer, for Steam Boilers using Salt Water.

By these, the density of the water in the Boiler is at all times accurately shown, and a saving of boiler and fuel is effected. They are adopted by the Admiralty, the Honorable Trinity Corporation, and others. Copies of Testimonials from Messrs. Penn, Messrs. Maudslay, and others, will be forwarded on application.

How's Engine-Room Telegraph, for communicating between Captain and Engineer. Society of Arts Prize Medal, 1855.

This is a Mechanical Telegraph, and by its peculiar construction, error or misunderstanding is rendered impossible. It is now extensively adopted, and gives great satisfaction.

How's Patent Fresh Water Apparatus for Ships' Use.

This apparatus is designed for the distillation of Fresh from Salt Water; and on long voyages, and where the supply of water is scanty, it will be found invaluable. Testimonials may be seen.

Patent Steam Pump and Fire-Engine for Ships' Use.

This Steam-pump occupies but a small space; works perfectly noiselessly, and throws an immense volume of water. An Illustrated Circular of Fresh Water Apparatus and Steam-pump combined, free on application.

How's Patent Machine for Cutting Bolts, Rods, Spindles, Wire, &c.

Simple in construction, inexpensive, occupies but little space, and will not easily get out of order.

A Pamphlet Illustrative of the above, sent free by post, on application to

A. P. HOW, ENGINEER,
81 MARK LANE, LONDON.

EVERY DESCRIPTION OF ENGINEERS' TOOLS, ENGINE ROOM STORES, &c., &c., SUPPLIED. (38)

SCOTT'S
PATENT GRASS SEED SEPARATOR,

which entirely extracts the Seeds of "COUCH," "TWITCH," "SPEAR," or "HAIR" GRASS, and other impurities from

PERENNIAL AND ITALIAN RYE-GRASS, &c.,

AND

SCOTT'S PATENT CARROT SEED BEARDING

AND

CLOVER AND TREFOIL MILLING OR DRAWING MACHINE,

which effectually removes the beard from Carrot Seed, rendering it fit for sowing with facility by drill or otherwise, and by the separation of abortive or diseased grains vastly increases its vegetative per centage. By a slight modification it is applicable to the other purposes before mentioned.

These Machines were admittedly the most novel, and, at the same time, the most useful and important to the Farmer of any exhibited at the late SMITHFIELD CLUB SHOW.

They may be seen at work at the Establishment of the Manufacturer,

Mr. T. MIDDLETON, Engineer, Southwark.

Communications to be sent to the Patentee, J. SCOTT, 111 Drummond Street, Euston Square, London, N.W. (48.)

THE ROYAL AGRICULTURAL SOCIETY OF ENGLAND'S
FIRST PRIZE REAPER.

BURGESS & KEY, PATENTEES AND SOLE MAKERS, 95 NEWGATE STREET, LONDON.

MANUFACTORY, BRENTWOOD, ESSEX.

BURGESS & KEY'S extensive Manufactory is wholly occupied in the Manufacture of

REAPING MACHINES AND GRASS MOWING MACHINES,

upon which they have concentrated their efforts since the year 1851. Their practical experience enables them to produce a Reaping Machine which can be depended on by the Farmer.

Owing to the excessive demand for last season, many orders were left unexecuted. BURGESS & KEY therefore earnestly request that orders for next season (1859) be sent as soon as possible, otherwise they cannot guarantee to deliver in time.

Price £42 10s. Net Cash, at the Works, complete with Conical Screw Divider for long Grain; without the Conical Screw, £40. Extra Knife, £1 5s. If other extras are supplied they are charged for. A man sent to start the Machine, if required, on payment of his expenses.

BURGESS AND KEY'S GRASS-MOWING MACHINE
(ALLEN'S AMERICAN PATENT).

Before introducing this Machine to the English public, BURGESS & KEY determined to fully test its capabilities, and the all-important point—durability. One Machine cut, on the farm of Mr. C. Hall, Havering, Romford, Essex, 83 acres Grass; and the same Machine afterwards cut, on the farm of Mr. Tabrum, Bovis Hall, near Brentwood, Essex, 100 acres Grass, and 20 acres Clover. The work done was declared to be better and lower than the scythe, and at the rate of 1 acre per hour. Orders have been received from both those Gentlemen, and numerous others, for Machines for next Season. Price £30.

BURGESS & KEY'S Manufactory is entirely devoted to REAPING MACHINES and MOWING MACHINES.

95 NEWGATE STREET, LONDON.—MANUFACTORY, BRENTWOOD, ESSEX.

FURTHER PARTICULARS AND CATALOGUES SENT ON APPLICATION. (39)

GLENFIELD PATENT STARCH,
USED IN THE ROYAL LAUNDRY,

AND PRONOUNCED BY HER MAJESTY'S LAUNDRESS TO BE THE FINEST STARCH SHE EVER USED.

WHEN YOU ASK FOR

GLENFIELD PATENT STARCH,
SEE THAT YOU GET IT,

as Inferior kinds are often substituted.

Sold by all Chandlers, Grocers, &c., &c. (7)

RANSOME'S PATENT IMPERISHABLE SILICIOUS STONE.—Chimneypieces, Balustrades, Capitals, Trusses, Terminals, Fountains, and Vases; also, Enamelled Stone Chimneypieces, of great beauty and novelty, at reduced prices. Monumental or Mural Memorials, Grave Stones, Space Markers, and Inscriptions for Cemeteries, &c., of every description, at the lowest prices.

RANSOME'S PATENTED PROCESS FOR PRESERVING STONE.—Invaluable in its application to Public Edifices and Private Residences. By this process the softest and most friable stone can be rendered impervious and imperishable, and decay at once arrested and prevented.

RANSOME'S PATENT STONE FILTERS FILTERING SLABS.—Manufactured for every Private or Domestic purpose, for Manufactories, Public Companies, Shipping, &c. Several hundred thousand gallons of water are filtered daily by Ransome's Patent Stone Filtering Slabs, for the town of Southampton. They have also been adopted by the Admiralty, the Board of Ordnance, the Colonial Land and Emigration Commissioners, and other Public Bodies for several years; also in the City of Rotterdam, with the most perfect success.

For particulars, specimens, illustrations, and agencies, apply to

Mr. FREDERICK RANSOME,
WHITEHALL WHARF, CANNON ROW, WESTMINSTER;

OR PATENT STONE WORKS, IPSWICH.

A liberal discount allowed to the Trade or to Shippers. (4)

A NEW DISCOVERY IN WASHING HOUSEHOLD LINEN.

NO FAMILY SHOULD BE WITHOUT HANCOCK'S UNIVERSAL WASHING MACHINE, It effectually cleanses the Crevices of Baby-linen, Collars, Wristbands, &c., without the possibility of injuring the Linen or Collars. Received 500 Testimonials.

PRICES.

No. 2 Washes 9 Shirts in from 3 to 10 minutes; or 4 Sheets in 5 minutes	£5 5 0
No. 3 Washes 12 Shirts in from 3 to 10 minutes; or 6 Sheets in 5 minutes	7 11 0
No. 4 Washes 18 Shirts in from 3 to 10 minutes; or 12 Sheets in 5 minutes	12 12 0

And all other Articles in proportion.

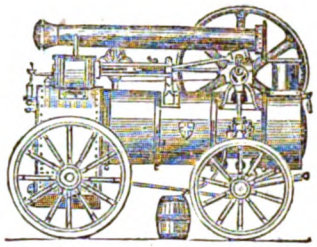
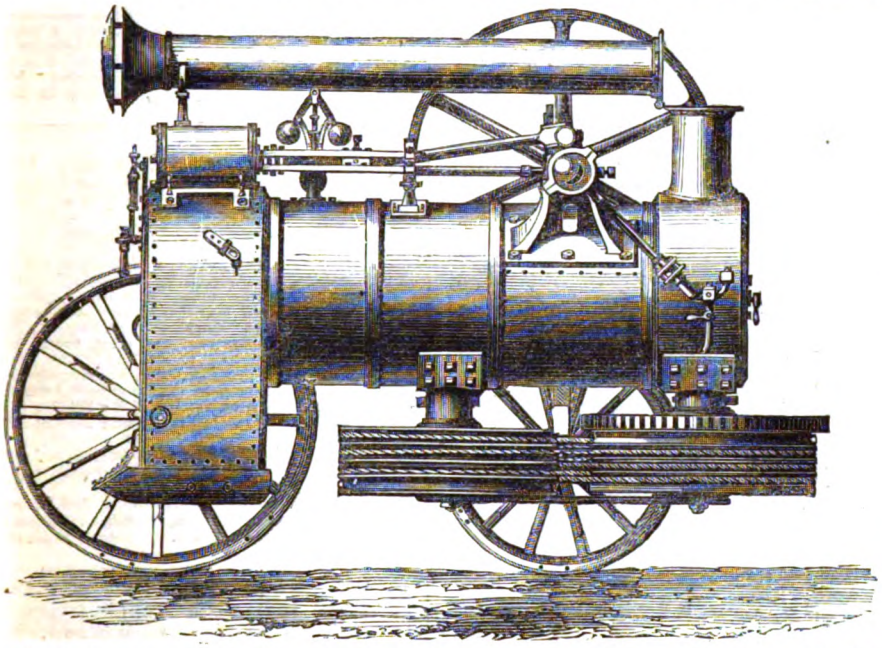
(34)



COLLINSON HALL'S PATENT WINDLASS AND STEAM PLOUGH AND IMPLEMENT GEAR.



The object of this mechanism is to render effective the WHOLE POWER of engines used in drawing ploughs or other implements in tilling land. This is accomplished by carrying the wire rope, in the form of the figure 8 round horizontal drums fixed (so as to be easily removable) under the engines. By this arrangement the evils arising from overlaying the coils of rope when wound upon the capstan principle are avoided, as also are those arising from an unequal wear of the ordinary horizontal pulleys. In the new arrangement the solid drum is constructed with several grooves, while the other is composed of as many independent pulleys as there are grooves in the drum. The upper or lower pulley, as the case may be, revolves in one direction, while the remaining ones revolve in the opposite direction. The solid drum only is driven directly by the engine, while the pulleys revolve by frictional contact.

The simplicity of this Gear is one of its chief recommendations, little or no framing being required. The axes being bolted to the bottom of the boiler, a simple rod or beam retains them in a vertical position. The Gear may be fitted and again unshipped from an engine (by means of keys through the axes, by which the Gear is retained in place) in less than ten minutes.

APPLICATIONS FOR LICENCES TO BE MADE TO

COLLINSON HALL, PRINCES GATE, ROMFORD, ESSEX.

TO BRASS-FOUNDERS, ENGINEERS, &c.

THE PATENT PLUMBAGO CRUCIBLE COMPANY having completed the enlargement of their premises, beg to call the attention of all users and shippers of Melting Pots to the great superiority of the PATENT CRUCIBLES, which have been used during the last three years by some of the largest melters in England and abroad. In addition to their capabilities of melting an average of from thirty-five to forty pourings; they are unaffected by change of temperature, never crack, but can be used till worn out, requiring only one annealing for several days' work, and become heated much more rapidly than ordinary pots, effecting thereby a saving of more than fifty ber cent. in time, labour, fuel, and waste. The Patent Plumbago Crucible Company also manufacture and import clay crucibles, muffles, portable furnaces, sublimate pans and covers, glass-pots, all descriptions of fire- standing goods, and every requisite for the assayer and dentists. For Lists, Testimonials, &c., apply to Battersea Works, London, &c. (43

JOHN DAVIS, 19 Percival-street, Clerkenwell, London, E.C. Established 1810.

DIE SINKER, SEAL ENGRAVER, METAL Stamper, Piercer, and Manufacturer of Metal Labels for Patent and other Articles, Tokens, &c.; Copying, Embossing, and Piercing Presses, Stamps, Punches, Press Tools, &c.

DAVIS'S PATENT SELF-INKING ENDORSING PRESSES, the most Complete and Useful yet made.

A Lever Embossing Press and Die, complete 15s. (51)

The Last Piece of Turnip cut.
J. MARTIN'S PATENT

CUTTING AND PULPING MACHINES, for TURNIPS, &c., from which the last piece cannot escape without being cut.

These Machines cut inside the barrel, are much easier to work than others, not so likely to get out of repair, the cylinder being made out of stout cast-iron; and the knives, fixing on outside, are easily replaced in the Field.

Price £5 5s. cash, at Llyn or Fakenham.

Orders, and applications for licences to make, to be apdressed to Mr. J. Martin, Barmer, Fakenham, Norfolk. (61)

FISHER'S PATENT TOBACCO PRESSING AND CUTTING MACHINES, with continuous sharp knives, is allowed to be the best and most complete Machines that ever could be invented to effect the three objects it is intended for, that is, Pressing, Cutting, and Sharping; all combined in one Machine. A man and a boy can cut six cuts per hour; any number of cuts from 20 to 100 in the inch can be given without stopping or changing a wheel or rigger.

Apply to Mr. FISHER, 12 Ranelagh-road, Thames-bank, London, S.W. (52)

HALKETT'S GUIDEWAY STEAM AGRICULTURE.—Every operation of the Farm performed by Steam, at a large reduction of cost, and a great improvement in the result upon the land. Early in February Mr. Halkett's Cultivator will again be exhibited in operation. Cards stating the days and place will be forwarded, with an Illustrated Pamphlet and a Paper read before the Society of Arts, upon receipt of two postage stamps. Office, 50 Chancery-lane, W.C. (72)

TO ENGINEERS' TOOL MAKERS, AND OTHERS.

THE ADVERTISER is desirous of meeting with an engagement as TOWN or DISTRICT AGENT for an Engineers' Tool Maker, or firm whose business lies amongst Engineers and practical men. He is an Engineer by profession, has for many years been engaged in bringing into operation several inventions, and can give unexceptionable references. A very moderate fixed salary only expected. Address M. C., MECHANICS' MAGAZINE Office, 166 Fleet-street. (75)

TAUNTON DISTRICT.—WANTED, by the Taunton Local Board of Health, a PERSON practically acquainted with levelling, drawing, general building and drainage works, repairs of roads, pavements, &c., to devote the whole of his time to the performance of the duties required by, and devolving on a Surveyor to said Local Board of Health. Salary £120. For any other particulars apply to the clerk, to whom all applications are to be sent on or before the 26th day of January next. References as to competency and integrity of character will be required. WM. MARWOOD, Clerk.
East-street, Taunton, 30th December, 1858. (68)

ENGINEERING PUPIL.—A good opportunity now presents itself in the office of a Civil Engineer to advance the interests of a young gentleman with a taste for the profession. Premium moderate. Address C. E. Reid's, Stationer, 15 Charing-cross, S.W. (69)

TO ENGINEERS, &c.—Partnership.—There is an opportunity for a gentleman of business habits, with £5,000, to succeed a retiring partner in a large and flourishing business in London. Time for bringing in the capital may be partially deferred or arranged in such a way as to accommodate the incoming partner. Address, personally, to S. N. Driver, Esq., solicitor, 13 Birchin-lane, Lombard-street, E.C. (70)

PUMPING MACHINERY.

GWYNNE AND Co., Engineers, London, manufacture and supply the following Machinery, of the most approved construction and with all the latest improvements:—Portable and Fixed Steam-Engines and Boilers of every description; Waterwheels, Windmills, Horse and Hand-power Machines; Pumping Machinery for the Supply of Towns, Cities, and Districts, and for the Irrigation of Coffee, Cotton, Indigo, Sugar-cane, and Rice Estates, for pumping out Coffer-dams, Canals, Dry Docks, Reservoirs, &c. They also manufacture and supply the Pumping and other Machinery for Paper, Pulp, and Fulling Mills, Breweries, Distilleries, Tanneries, Starch Works, Bleaching, Dyeing, and Calico Printing Works, Chemical Works, Silk, Cotton, and Flax Mills, and Manufactories in general. All Letters not paid will be refused. Illustrated Price Lists forwarded on receipt of Six Postage Stamps.—GWYNNE AND Co., Hydraulic and Mechanical Engineers, Essex-wharf, Strand, London.

For Exportation.—The above can be obtained through British Merchants, Shippers, and Colonial Agents. (24)

VITRIFIED BLUE BRICKS are delivered at the Nine Elms Station, London, at 80s. per 1,000.—Address, G. H. OGSTON, J. M. Paine's Silica Works, Farnham, Surrey. (56)

BY HER MAJESTY'S ROYAL LETTERS PATENT.

PATENT SPHERICAL SELF-ADJUSTING BEARINGS, which do not heat in work. The advantages possessed by these Bearings are:—

1st. They are Self-adjusting; and, consequently, can be put down by the most ordinary Mechanic.

2nd. They are not liable to heat, even at high speeds.

3rd. They remain constantly parellel to the Spindle; and, therefore, wear equally all across the Bearing.

4th. They require only a very small quantity of oil.

Engravings and Prices forwarded on application to the Patentees.

WALLIS & HASLAM,
Engineers and Iron Founders, North Hants Iron Works, Basingstoke. (11)

FOR SALE a SISSON ACHROMATIC EQUATORIAL, by Troughton and Simms, London. Object glass 5¼ inches clear aperture, 7ft. 8 inches focal length, polar axis 11ft. 3 inches long by 11 inches square; wheels brass, 2 feet diameter. The telescope has a micrometer and a large battery of eye-pieces, and a great variety of diaphragams. A very superior 8¼ feet Munich Telescope, by Merz and Sons, with or without its stand; tube mahogany object glass, 6¾ inches clear aperture, with micrometer by Dollond, and a large battery of eye-pieces. A heavy Iron Mortar Equatorial, suitable for a tube of from 10 to 15 feet, with declination and right ascension circles; this style of equatorial is remarkable for its stability and freedom from tremor. For particulars apply to Mr. How Miller, Ochtertyre, Crieff, N.B. (47)

BRICK AND TILE WORKS.

TO BE LET, on Lease or otherwise, with Plant and Clayton's Machine complete, and with immediate possession.

The ground is situated on the east side of London; it contains very superior materials for Bricks and Drainage Tiles, and a good supply of water without the cost of pumping. Hack-ground and Drying-sheds spacious and well situated. A railway-siding into the ground, with ample accomodation for making three or four millions per annum. For particulars, apply by letter to C. W., 166 Fleet-street, London, E.C. (17)

LIST OF MISCELLANEOUS TENDERS INVITED, AND ENGAGEMENTS OPEN.

RAILWAY WORKS.—The directors of the Fortpatrick Railway are prepared to receive tenders for the following works.— First, a viaduct over the Ken, adjacent to the ferry, at Boat of Rhone, about seven miles north from Castle Douglas, to consist of three large and four small spans. In addition to the masonry, it will require about 200 tons of wrought iron in girders, and 90 tons of cast iron. Second, a portion of the railway to be called the "Glenluce Contract," extending from a point a cut half a mile west of Kirkcowan, and terminating at a point about three-quarters of a mile west of Glenluce, in length upwards of nine miles Third, a portion of the railway to be called the "Stranrear contract," extending from the termination of the Glenluce contract to a point about 400 yards beyond Stranrear, in length upwards of eight miles. Separate tenders for each contract. The rails to be supplied by the company. Drawings and specifications at the offices of the engineers, Messrs. H. and E. Blyth, 135 George-street, Edinburgh, on and after 21st January, from which day the draft of a contract deed will lie at the secretary's office in Stranrear, or at that of the engineers in Edinburgh. Forms of tenders to be had of either the secretary or the engineer. Date of return to the secretary February 5. To be determined upon at one o'clock on the 8th February, at the County Hotel, Carlisle, when intending contractors or their agents must be present. The assistant engineer will be at the Castle Arms Inn, Castle Douglas, at 11 on the 25th January, to go to the site of the viaduct, will leave the Galloway Arms, Newton Stewart, at 9 on the following day, and arrive at 10 at the commencement of the contract near Kirkcowan, for the Glenluce contract; and on the 27th at 9 will leave the King's Arms, Glenluce, for the Stranraer contract, remaining at Glenluce on the 28th.

RAILWAY, *London and North-Western.*—The directors solicit tenders for the construction of the Shropshire Canal Conversion, being from a point on the Shropshire Canal, near the turnpike road from Wellington to Shiffnall, in the parish of Wombridge, to the terminus at Coalport, on the river Severn, being a distance of about 5¾ miles. Plans, &c., ready for inspection on and after Monday, 10th January, at the office of the engineers, Messrs. Locke and Errington, 13 Duke-st., Westminster. Tenders, marked "Tender for works, Shropshire Canal Conversion," to be delivered not later than February 7, addressed to the secretary (Mr. C. E Stewart) at the Euston Station.

RAILS.—The directors of the Manchester, Sheffield, and Lincolnshire Railway are prepared to receive tenders for 1,200 tons of rails, 72lbs. to the yard; also 200 tons of bracket chairs to patterns, to be furnished on application to the company's engineer at Manchester. Tenders to be sent in to Edward Ross, Secretary, London-road Station, not later than Thursday, January 13.

RAILS.—The directors of the Edinburgh and Glasgow Railway Company require tenders for 1,300 tons of 75-lb. rails, to be delivered at any station on their line (Queen-street excepted), one-half before 1st March, the other half before 1st of April next. The rails are to be of the best quality and make. Specifications may be had at the office of Mr. Adie, the Company's engineer. Tenders on or before 17th of Jan. inst.

RAILWAY CHAIRS.—The directors of the Edinburgh and Glasgow Railway Company are prepared to receive tenders for the supply of about 436 tons railway chairs, good sound castings of No. 2 pig iron, to be delivered at any station on their line (Queen-street excepted) one-half before 1st March, the other half before the 1st of April next. Tenders to be lodged on or before 17th of January inst. Edinburgh and Glasgow Railway Engineer's Office.

RAILWAY SLEEPERS.—The directors of the Edinburgh and Glasgow Railway Company are prepared to receive tenders for the supply of about 20,000 sleepers, one-sixth of the quantity to be 9 feet long × 10 × 5, and the remainder 9 feet long × 9 × 4½. To be delivered at any station on their line (Queen-street excepted) on or before 1st of March next. Offers may be for one-half the quantity to be of Scotch larch and the other half to be of Scotch fir. Specifications to be had of Mr. Adie, Company's Engineer. Tenders to be lodged on or before 17th of January inst.

PLATE IRON, *East India Board.*—On the 14th instant the Finance, Home, and Public Works Committee of the India Council will be ready to receive proposals in writing for the supply of best plate and sheet iron; also British iron. The conditions of these two contracts may be had on application at the Secretariat office where the proposals must be left before eleven in the forenoon of the 14th.

WROUGHT IRON BRIDGE, *Victoria.*—Plans have been on view only since Monday last, at the offices of Mr. Carr, 4 Victoria-street, Westminster Abbey, London, and tenders must be sent in to Mr. W. L. Stoney, care of Mr. Carr, before noon to-morrow (January 8), for the construction of a lattice girder bridge, of three openings, in all about 300 feet, for the river Yarra, Victoria, to be shipped at London or Liverpool.

RAILWAY WAGGONS.—The Waterford and Limerick Railway Company are in immediate want of from sixty to seventy goods and cattle trucks. Tenders received to the 18th January. Specifications at the offices of the company, the Mall, Waterford. Mr. Thos. Ainsworth, the secretary, will be glad to hear from parties having waggons ready for immediate delivery.

COLLIERY STORES.—The owners of the Backworth and West Cramlington Collieries invite tenders for their year's supply of bar, bolt, nut, and hoop iron; rails and chairs (say 50 tons) forgings; sand and loam castings; Memel, Norway, and other timber; nails, shovels, and other hardware goods; hempen and wire-rope; spunyarn, hemp, and oakum; bucket leather, strap hides, and saddlery goods; waggon soles, sheths, and coverings; whale and pine oil; candles, tallow, grease, lamp cotton, and cotton waste; fire-bricks and lime. To be delivered, free of cost, either at Cramlington Station, Whitehill Point Staith, or the Colliery. Tenders, stating terms of payment, to be sent to the Backworth Colliery office, Backworth, on or before the 10th proximo.

GAS-PIPES.—GEELONG.—Tenders are wanted immediately for cast-iron pipes, bends, branches, syphons, &c., for the Geelong Gas Company, Victoria, Australia. Specifications at the office of Mr. J. Scoltock, inspecting engineer, 75 Old Broad-street, London, and at the Company's Agents', Messrs. John Warrack and Co, Leith, with whom tenders must be lodged on or before the 20th January.

IRON GASOMETER — CAST-IRON TANK. — The Great Coggeshall Gas and Coke Company require an iron gasometer and cast-iron tank to hold 5,000 or 8 000 feet of gas. Tenders to include carriage, fixing, and all the apparatus necessary for the perfect working, to be sent to Mr. Wm. Doubleday, secretary, Coggeshall, who will supply any further information required.

BRITISH OAK TIMBER—THICK STUFF AND PLANK—TREENAILS.—THE NAVY.—The Navy Commissioners give notice, that at two o'clock on the 25th inst, they will be ready to treat with such persons as may be willing to contract for supplying 26,000 loads of British oak timber; 9,500 loads of British oak, thick stuff, and plank; and 1,800,000 British oak treenails, to be delivered at her Majesty's dockyards, by the 31st of Dec., 1861, at prices including all carriage and other expenses. A tender may be made for the whole contract, but not for less than the quantity required at any one yard. Forms of tender and particulars at the office of the Storekeeper-General of the Navy, Somerset-place. Tenders to be presented by principals, or agents duly authorised in writing, addressed to the Secretary of the Admiralty; and having "Tender for British Oak" in the left-hand corner. They must be accompanied by a letter signed by two responsible persons engaging to become bond with the person tendering, in the sum of £20,000, for the due performance of the whole, or in a due proportion for a part only.

PUDDLED TIMBER COFFER DAM. — MERSEY DOCKS ESTATE.—The Mersey Docks and Harbour Board are prepared to receive tenders for the construction, maintenance, and removal of a puddled timber coffer dam, at the entrance to the intended deep low-water basin at Birkenhead. Plans, &c., of the engineer, at the Dock-yard, Cobourg-dock, Liverpool. Tenders to be duly endorsed, and addressed to the Chairman of the Committee of Works, and left at the office of the Secretary, Dock-office, Liverpool, not later than eleven o'clock on the forenoon of January 22. The Board will decline all the tenders if they deem it necessary.

FACTORY, &c.—The directors of the King's Cross Patent Wheel Company are prepared to enter into a contract for erecting a factory, buildings, offices, &c., at King's Cross. Plans, &c., from 12 till 3, till 17th January, at 23 Martin's-lane, Cannon street, City.

ECCLESIASTICAL EDIFICES.—The necessary particulars as to the time of inspecting the plans, delivery of tenders, &c., in connection with the rebuilding of the parish church of St. Michael, Farnsfield, Notts, may be had on or before the 1st of February. at the office of Messrs. Hine and Evans, architects, Nottingham.——The same in regard to tendering for works required to be done in the rebuilding of the parish church of St. Giles, Darlton, Notts.——The like respecting the erection of a tower and spire to the new church, Brackenfield near Alfreton, Derbyshire.——Similar in every respect to the three foregoing is the notice inviting tenders for the rebuilding of the parish church of St. Oswald, Dunham-upon-Trent, Notts—for all of which undertakings Messrs. Hine and Evans are the architects.

GRAMMAR SCHOOL, PREPARATORY SCHOOL, NEW-ROAD.—The trustees of the Bedford Charity ask for tenders for the enlargement of the Grammar School, the erection of a new Preparatory School, and the making of a new road. Plans, &c., at the offices of Mr. James Horsford, architect, Bedford. Separate tenders duly endorsed to be delivered at Mr. Horsford's office at or before 11 in the forenoon of January 24.

CHAPEL SCHOOL, *War Department.*—Newbridge Barracks, County Kildare. Information at the Commanding Royal Engineers' Office, Lower Castle-yard, Dublin, and at the Royal Engineers' offices at Curragh and Newbridge. Letters of tender endorsed "Tenders for Work at Newbridge," be sent by January 22, to "The Director of Contracts, War Office, Pall Mall, London."

MANAGER OF COPPER ROLLING MILLS. — At Llanelly, South Wales, a manager, with a practical knowledge of the rolling of copper and yellow metal, is required. Applications to C. W. Nevill, Esq., Copper Works, Llanelly, South Wales.

SCIENTIFIC BREWER.—A head brewer, possessing a thorough knowledge of chemistry and of the practice of brewing, is required in a large establishment. Z, care of Messrs. Wigan, White, and Wigan, Hibernia Chambers, London Bridge, Southwark.

MAY BE PURCHASED.—20,000 Scotch fir sleepers, from James Forbes, 45 High-street, Inverness, N.B.

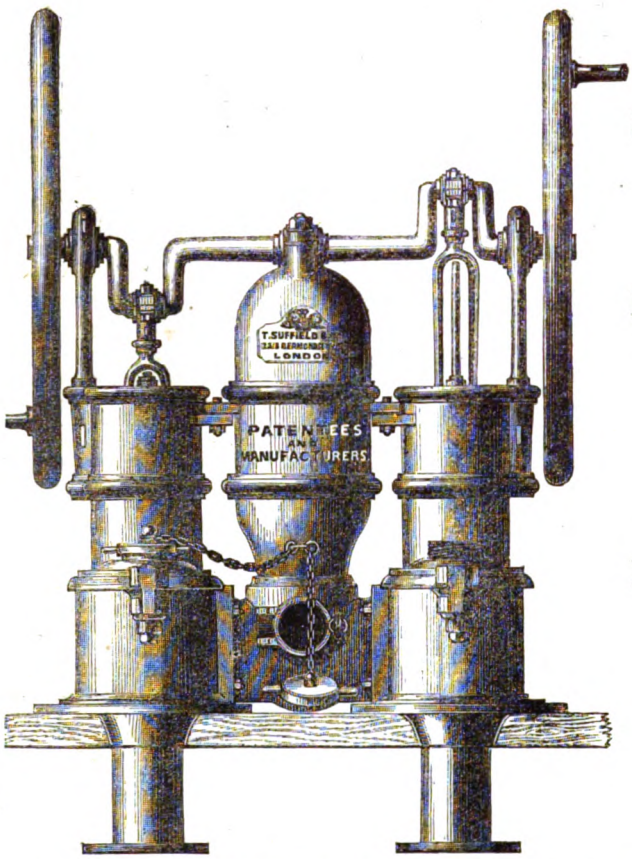
SHIP-OWNERS, SHIP-BUILDERS, AND COMMANDERS OF STEAM AND SAILING VESSELS,

to the Simple and Efficient Arrangements of their

PATENT PUMPS.



Ships' Pumps

AND

Fire Engines,

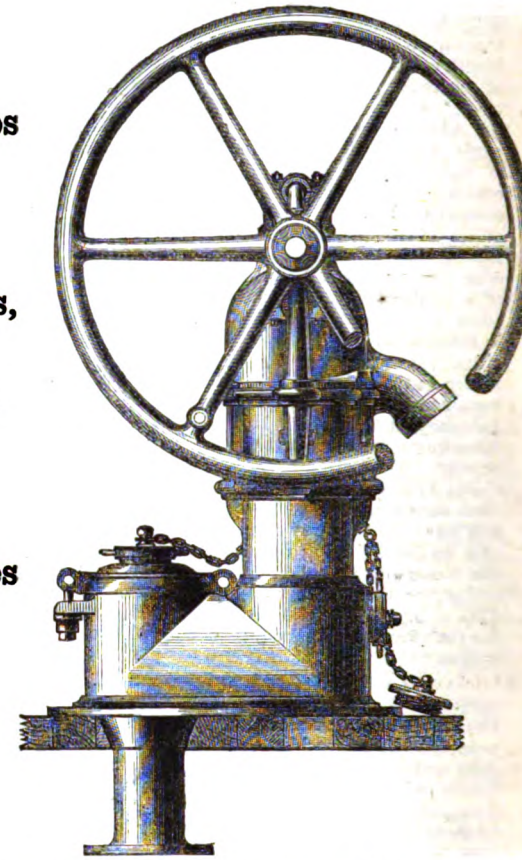
Fixed and Portable.

WITH

Patent Valves

AND OTHER

Improvements.



These Pumps are free from that liability to choke which is common to other Pumps, and their Working Parts are not susceptible of derangement either from wear or from being long out of use. They pass entirely through them, with ease, any substance that may enter the Suction Pipes. The Novelties in these Pumps are their adaptation to the varied duties of Ships' Pumps, the facilities they afford for Cleansing the Suction Pipes, and for Sounding or Examining the Valves; the readiness with which they may be used for Ventilating the Bilge, or for acting as a Syphon either for Watering the Ship, or for extinguishing Accidental Fires on board; the rapidity with which they can be converted into Fire Pumps, or be applied to the Washing of Decks; and their capability of Pumping from Several Compartments.

T. SUFFIELD AND CO.

Also respectfully solicit the attention of STEAM SHIP BUILDERS and OWNERS to their Large and Varied STOCK of

ASSORTED STORES FOR MARINE PURPOSES.

They keep a Large Stock of Goods, of their own Manufacture and from the Best Makers, constantly on view; so that by a visit to their Works or Depôt, much valuable time may be saved by Managers, Engineers, and other Gentlemen who may require such Stores, together with a further saving in the cost of such Articles.

CLAYTON, SHUTTLEWORTH, AND CO.,

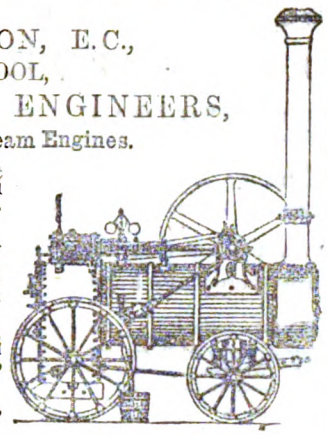
OF LINCOLN,

78 LOMBARD STREET, LONDON, E.C.,

AND 36 DALE STREET, LIVERPOOL,

AGRICULTURAL AND GENERAL ENGINEERS,

And Manufacturers of Portable and Fixed Steam Engines.



Combined Threshing Machines, which dress the corn ready for market at one operation. Grinding Mills, Saw Benches, Pumps for Irrigation and Mining purposes, with all necessary gearing for being driven by steam power. Full particulars and estimates given on application to the above address.

C. S. and Co.'s PORTABLE STEAM ENGINES are adapted for every purpose to which steam-power can be applied. When intended for winding, they are fitted with reversible link motion and winding gear. They are easy of removal, as may be seen by the engraving, and can be set to work immediately on arrival.

C. S. and Co. are now doing an extensive foreign and colonial business, and are prepared to send off engines and machinery of the before-mentioned kinds in a few days from the date of order. They would also call attention to the important *reduction in prices* made for the new year.

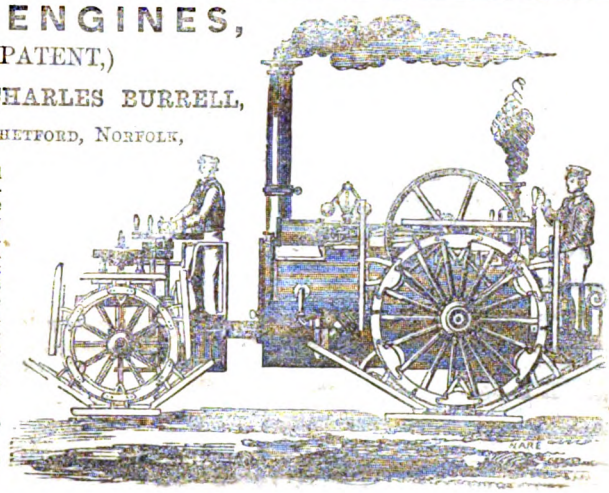
For Exportation.---The above can be obtained through British Merchants, Shippers, and Colonial Agents. (23)

TRACTION ENGINES,

(BOYDELL'S PATENT,)

MANUFACTURED BY CHARLES BURRELL,

ST. NICHOLAS WORKS, THETFORD, NORFOLK,



And ordered for India, Australia, and South America, may now be seen, complete and in course of construction at the above works. BOYDELL'S TRACTION ENGINES AND ENDLESS RAILWAY will draw heavier loads over good roads than any other traction engine, and on soft and bad roads will draw heavy loads where no other traction engine can move itself. All objection to the wear and tear of these Engines is entirely removed by the use of Charles Burrell's improved patent Wrought Iron Wheels, fitted with Rails and Tyre, as well as all the wearing parts, of Steel.

Apply also to Mr. Hemming, 47 Mark Lane, E.C.

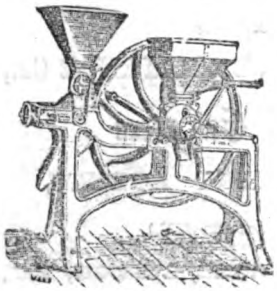
E. R. & F. TURNER,

ST. PETER'S IRON WORKS, IPSWICH,

PRIZE CORN AND SEED CRUSHING MILLS.



THESE MILLS obtained the First Prizes of the Royal Agricultural Society at the Norwich, Gloucester, Lincoln, and Carlisle Shows;

The Prizes of the Bath and West of England Society, at the Annual Meetings' 1854, 1855, 1857, and 1858;

The Gold Medal and Prize of 150 Francs at the French Universal Exhibition of Agriculture, 1856;

Large Silver Medal at the Austrian Imperial Agricultural Exhibition, 1857;

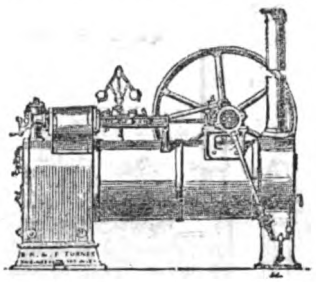
The Highland Agricultural Society's Prize for the Best Linseed Crusher, at Aberdeen, 1858;

And numerous Prizes from Local Societies.

For Crushing Oats, Linseed, Barley, Malt, &c., and Grinding Beans and Peas, these Mills are unrivalled. Numerous varieties are made, adapted for the requirements of all who use crushed corn or seed.

E. R. & F. TURNER'S TWO-HORSE POWER STEAM ENGINES

Are of superior design and first-class workmanship, and have proved themselves to be highly efficient, economical, and durable. They are applicable for working Thrashing Machines, Chaff Cutters, Crushing Mills, Pumps, Brick and Tile Machines, &c., and may be had as fixtures on Iron Pedestals, as here represented, or made Portable, on Wood or Iron Wheels. Combined Thrashing Machines are made expressly adapted for these Engines.



E. R. & F. TURNER also claim attention to the following Articles of their manufacture, each of which they can confidently recommend:—

PATENT CRUSHING AND GRINDING MILL—a combination of Crushing Rollers and Mill Stones, capable of either crushing or grinding to meal every description of corn, pulse, or seed.
GRINDING MILLS—with French or Derbyshire Stones, from 18in. to 3 ft. diameter, compactly fitted upon strong iron frames.
CHAFF CUTTERS—for Hand or Power, with iron frames and concave knives, cutting various lengths.
OILCAKE BREAKERS—made entirely of iron, and capable of breaking all description of cake for sheep and beasts.
HORSE GEARS—with intermediate motions, all of iron, suitable for small Thrashing Machines, Chaff Cutters, Crushing Mills, &c.
CIRCULAR SAW TABLES—with improved adjusting guide fence, and with or without boring apparatus.
THRASHING MACHINES—for 2, 3, and 4 Horse, suitable for exportation.
PORTABLE STEAM ENGINES—from 2 Horse Power, and upwards.
COMBINED THRASHING and WINNOWING MACHINES.
FIXED STEAM ENGINES—from 4 Horse Power.

Illustrated Catalogues, with Prices and full particulars, sent free on application. (59)

IMPROVED MACHINERY FOR AGRICULTURISTS.

RICHARD GARRETT & SONS,

LEISTON WORKS, SAXMUNDHAM, SUFFOLK,

(ESTABLISHED A.D. 1778),

EARNESTLY solicit the continued support of their numerous Friends, Agriculturists, Shippers, and others; the additions made to their Works during the present year, in the erection of new sets of Workshops, fitted with the best mechanical appliances for producing Machinery of the most improved construction, expeditiously and economically, justifies their soliciting increased support, while their leading reputation as Inventors and Manufacturers of FIRST CLASS Agricultural Machinery, is a sufficient guarantee that every Machine supplied from Leiston Works will prove to the entire satisfaction of the purchaser.

R. G. & S. are now manufacturing the following Machines and Implements, which they guarantee to be thoroughly efficient in every respect:—

PORTABLE AND FIXED STEAM ENGINES. } From 4 to 40 Horse Power, suited for every kind of work
SELF-PROPELLING AND TRACTION ENGINES. } to which Steam Power is applied.
STONE GRINDING MILLS.
MORTAR AND PUG MILLS.
MILLWRIGHTS' WORK of all kinds.
SAWING MACHINERY, from 4 fo 20 Horse Power.
BRICK AND TILE MACHINES.

IMPROVED SETS OF FARM MACHINERY, for Large Occupations.
PORTABLE AND FIXED MACHINERY, for Thrashing and Dressing Corn.
THE PRIZE BOLTING AND OPEN-DRUM HORSE-POWER THRASHING MACHINES.
CORN DRESSING MACHINES, for Hand, Horse, Water, and Steam Power.
BARLEY AVELLING MACHINES.
CHAFF CUTTERS, for Hand, Horse, Water, and Steam Power.
PATENT TURNIP CUTTING AND PULPING MACHINES.

THE PRIZE CORN AND SEED DRILLS.
PRIZE CORN AND SEED DRILLS WITH MANURE APPARATUS.
PRIZE SEED AND MANURE DRILLS.
LIQUID, SEED, AND MANURE DROP DRILLS.
CHAMBER'S PATENT BROADCAST MANURE DISTRIBUTOR.
GARRETT'S PATENT HORSE HOE for all Crops.
PATENT REVOLVING HOES for Root Crops.
IMPROVED PLOUGHS AND REAPING MACHINES.
&c. &c. &c.

Of which full detailed particulars will be found in R. G. & SONS' ILLUSTRATED CATALOGUE, sent postage free to any address, in English, French, or German; and any of the above Machines will be shown in operation at R. G. & Sons' Farm, near the Works, on their receiving a few days' notice.

A Copy of R. G. & SONS' new COLONIAL LIST will be forwarded free to any of the Colonies, and Shippers will be supplied with these lists, with their names and addresses printed on, free of charge, by making application for the same.

ADDRESS—R. GARRETT & SONS, LEISTON WORKS, SAXMUNDHAM, SUFFOLK. (57)

WATER POISONED BY LEADEN PIPES.

"The above engraving represents accurately a section of a leaden pipe, which was employed for a short time in conveying water from a well on the grounds of Mr. Dick, of Bonchurch, Isle of Wight. The water has cut these deep pits almost through the pipe, and not only upon the portion which we have illustrated, but has formed similar chasms throughout the centire length."—*Expositor.*

Poisoned Water Preventable.

BY THE USE OF GUTTA PERCHA TUBING.

The Gutta Percha Company have been favoured with the following letter,

From Dr. MURRAY, Hull.

"It is impossible to conceive of anything more injurious, or destructive to the health of the community than the use of *leaden pipes* for the conveyance of water. The poisonous salts of lead thereby communicated are most insidious and subtle. I hail with gratitude the substitution of Gutta Percha Tubing. I have had the leaden pipe of my own house removed, and its place supplied with one of Gutta Percha. Nothing can be better. I have also recommended it to others, who have adopted the expedient.

Resistance of Frost.

The Gutta Percha Company have been favoured with the following Letters in reference to the non-conducting properties of Gutta Percha Tubing, in the resistance of Frost.

From J. ARMSTRONG, Esq., M.D., Gravesend.

"My private house, which was supplied with your Gutta Percha Tubing some five or six years ago, has never required the slightest attention; and previously, there was no winter passed that we were not deluged in consequence of the bursting of the leaden pipes."

From HENRY BROWN and SONS, Western Works, 108 Rockingham-street, Sheffield.

"We have now a positive proof of the frost-resisting properties of the Gutta Percha Piping. On our premises we have a leaden Pipe and a Gutta Percha one lying side by side. The leaden one has been completely frozen up at least ten days, and the Gutta Percha one is still unaffected.

STEAM ENGINES FOR SALE.

PORTABLE STEAM ENGINES, from 6 to 12 horse power,
STATIONARY STEAM ENGINES, from 4 to 50 horse power,
TUBULAR BOILERS, from 4 to 50 horse power,
CORNISH BOILERS, from 4 to 50 horse power,

Are in hand, and can be despatched on eight days' notice. Prices moderate. Workmanship and Material of the best description.

Apply to R. THORNTON & Co., St. Leonard's Iron Works, Edinburgh. (60)

GLADSTONE & Co., CONTRACTORS and ENGINEERS.

2 John-Street, Minories, London, E.C.,

Are prepared to ESTIMATE FOR and CONSTRUCT BRIDGES, PIERS, JETTIES, &c., in Iron, Wood, or Stone. Also to supply Cranes, Girders, Turntables, and Railway Work and Plant generally. (81)

ENGINEERING AND MECHANICAL DRAWING CLASSES.—Instruction given in Engineering and Mechanical Drawing, comprising the preparation of plans, elevations, and sections of marine and locomotive engines, with the detail and working drawings; also the method of delineating screws, bevel wheels, &c.; orthographical projection, and tinting, shading, and colouring taught.—For prospectuses of the Day and Evening Classes apply to Mr. T. J. HILL, at the offices, 15, Old-street, City-road. 73)

ENGINEERS' MACHINE TOOLS ready for delivery, and in progress: for Planing, Slotting, Shaping, Boring, Drilling, Screwcutting, Parallel and Cross-surface Turning; Wheel Cutting, Bolt and Nut Screwing; Nut Shaping, Washer Making, Rivet and Railway Spike Making, Boiler-plate Bending, Shearing, Punching, and Rivetting.

MACHINE TOOLS for other purposes made to order.

JOHN TODD & Co.,
Kent Iron Works, Bridge-street, Greenwich (92)

NOTICE OF DIVIDEND.

BANK OF DEPOSIT, No. 3 PALL-MALL EAST, LONDON, S.W.—The Warrants for the Half-yearly Interest, at the rate of 5 per Cent. per Annum, on Deposit Accounts, to the 31st December, are ready for delivery, and payable daily between the hours of ten and four.

PETER MORRISON, Managing Director.

10th January, 1859.

Prospectuses and Forms sent free on application. (91)

TO MARINE ENGINEERS, OR SHIP-BUILDERS.

THE PROPRIETOR of a VALUABLE PATENT for Double-expansive Marine Engines (by which great economy of space and fuel is obtained) is desirous of entering into arrangements with a respectable firm for the construction of the same. An adequate portion of the patent-right would be assigned by the advertiser to any firm taking the matter up; and he would render all assistance in his power, either in London or elsewhere, amongst ship-owners (to many of whom he is well known), in obtaining contracts, &c. Unexceptionable references given. Address C. E., MECHANICS' MAGAZINE Office, 166, Fleet-street. (76)

MARINE ENGINE DRAUGHTSMAN.

WANTED, the Assistance of a THOROUGHLY COMPETENT MARINE ENGINE DRAUGHTSMAN, to prepare finished and working drawings of a newly patented marine engine. The drawings may be executed either at the applicant's own residence or at the offices of the advertiser. None need apply who are not well accustomed to designing marine engines, and thoroughly acquainted with their details as carried out by the best makers. Applications stating where employed, and the rate of remuneration required, to be addressed to X. Y. Z., MECHANICS' MAGAZINE Office, 166 Fleet-street. (74)

J. HOPKINSON & Co., IMPROVERS and MANUFACTURERS of the STEAM-ENGINE INDICATOR of the largest and best description, price £4. 4s., including 7s. 6d. edition of "The Steam Engine explained."

HOPKINSON'S PATENT MERCURIAL STEAM-PRESSURE GUAGES, to indicate up to 30lb., 40s.; to 70lb., 63s.; to 80lb., 100lb., or 120lb., 84s., including quicksilver.

HOPKINSON'S PATENT COMPOUND SAFETY VALVES, for preventing Boiler Explosions.

Apply BRITANNIA WORKS, Huddersfield. (33)

EDWIN JEWITT, ENGRAVER ON WOOD AND DRAFTSMAN, 1 Pickett-place, Strand, near Temple-bar. Engineering, Scientific, and Mechanical Designs accurately engraved. Manufacturers and Tradesmen's Catalogues Illustrated. W.C. (84)

TO ENGINEERS, ARCHITECTS, PATENT AGENTS, &c.

PHOTOGRAPHS OF THE HIGHEST CLASS and of any size, taken and reproduced at a most moderate rate of charge. Reproductions of faultless accuracy, of Machinery, Models, Drawings, &c. Orders attended to in town and country. Estimates forwarded.

SPENCER, READ, & Co., 4 Agar-street, Strand. W.C. (92)

FURNACE DOORS AND BARS.—Steam increased, fuel saved, and smoke prevented, by the PATENT REGULATING AIR-DOORS. Great economy from using the "Doubly-durable" fire bars.

J. LEE STEVENS, 1 Fish-street-hill, E.C. (87)

FIRE BRICKS.—THE FARNHAM INDESTRUCTIBLE SILICIOUS FIRE BRICKS have been greatly REDUCED in PRICE, and will be delivered at the Nine Elms Station, London, at 90s. per 1,000.—Address, G. H. OGSTON, J. M., Paine's Silica Works, Farnham, Surrey. (35)

HART & SON, MALLEABLE IRON-FOUNDERS, 4 Vine-street, York-road, Lambeth.

Orders for Malleable Iron Castings executed within a week. (77)

HALKETT'S GUIDEWAY STEAM AGRICULTURE.—Every operation of the Farm performed by Steam, at a large reduction of cost, and a great improvement in the result upon the land. Early in February Mr. Halkett's Cultivator will again be exhibited in operation. Cards stating the days and place will be forwarded, with an Illustrated Pamphlet and a Paper read before the Society of Arts, upon receipt of two postage stamps. Office, 80 Chancery-lane, W.C. (72)

WANTED, BY AN ESTABLISHED MANUFACTURER of SELF-ACTING ENGINEERS' TOOLS, a person to be regularly amongst the trade in London and the South of England soliciting orders. No one need apply who is not thoroughly acquainted with the business and the engineers, &c., of the district, and who cannot give unexceptional reference and security.—Apply by letter, post paid, to A 1, "Mechanics' Magazine" Office, Fleet-street. (29)

FISHER'S PATENT TOBACCO PRESSING AND CUTTING MACHINES, with continuous sharp knives, is allowed to be the best and most complete Machines that ever could be invented to effect the three objects it is intended for, that is, Pressing, Cutting, and Sharping; all combined in one Machine. A man and a boy can cut six cwt. per hour; any number of cuts from 20 to 100 in the inch can be given without stopping or changing a wheel or rigger.

Apply to Mr. FISHER, 12 Ranelagh-road, Thames-bank, London, S.W. (52)

RAILWAY AXLE-BOXES.

WHEREAS on the 14th December instant, a Verdict was given for the Plaintiff in the action of "Bruff v. Marshall and others," tried before the Lord Chief Justice and a Special Jury at Guildhall, whereby the Patents of the Railway Axle-Box Company were substantiated. NOTICE IS HEREBY GIVEN, that legal proceedings will be instituted against all Manufacturers and others adopting or using any of the Company's Patents, including those of Adams and Richardson, Wrighton, Normanville, Vigurs, McConnell, and Miller, without the Company's express licence in writing. Terms of licences and other particulars may be obtained from the Manager, Mr. P. M. Parsons, 9 Arthur-street West, London-bridge, E.C.

Dated 22nd December, 1858.

(Signed) E. BENHAM, 18 Essex-street, Strand.
J. HENRY JOHNSON, 47 Lincolns-Inn-Fields.
Joint Solicitors to the Railway Axle-Box Company. (7)

BRICK AND TILE WORKS.

TO BE LET, on Lease or otherwise, with Plant and Clayton's Machine complete, and with immediate possession.

The ground is situated on the east side of London; it contains very superior materials for Bricks and Draining Tiles, and a good supply of water without the cost of pumping. Hack-ground and Drying-sheds spacious and well situated. A railway-siding into the ground, with ample accomodation for making three or four millions per annum. For particulars, apply by letter to C. W., 166 Fleet-street, London, E.C. (17)

Weekly sales by Auction, twice a day.—Notice.

MESSRS. BOOTH and Co., at the request of friends and customers, respectfully announce that in future their monthly SALE of WOOD and IRON GOODS, building materials, shop and other fittings, tools, implements, stock stoves, &c., of all kinds connected with mechanical trades, will be held weekly, on every Tuesday, at 1 for 2 o'clock, at the Builder's Sale Grounds, 23 and 24 Marylebone-road, W. And further notice, that evening sales are in preparation, to be held on the same dates for the sales of tools. Persons wishing to send in goods will be supplied with lotting forms, terms, and full information gratis, on application or by post with the builders' sales, plan, and catalogue of sale for two stamps. Direct to Booth and Co., at the premises as above, or the Building Trades' Registry office, 13, Eastcheap, London, E.C. (93)

TO STEAM SHIP OWNERS, ENGINEERS, AND OTHERS.

How's Patent Steam Engine Counters, can be read at sight.

These Counters register the number of revolutions made by an engine or other mechanism. They may be used for ascertaining the duty of Pumping Engines and Water-wheels; the revolutions on board a steam-vessel; to calculate the slip of the propeller; and in a locomotive to test the slip of the wheels.

How's Patent Salinometer, for Steam Boilers using Salt Water.

By these, the density of the water in the Boiler is at all times accurately shown, and a saving of boiler and fuel is effected. They are adopted by the Admiralty, the Honorable Trinity Corporation, and others. Copies of Testimonials from Messrs. Penn, Messrs. Maudslay, and others, will be forwarded on application.

How's Engine-Room Telegraph, for communicating between Captain and Engineer. Society of Arts Prize Medal, 1855.

This is a Mechanical Telegraph, and by its peculiar construction, error or misunderstanding is rendered impossible. It is now extensively adopted, and gives great satisfaction.

How's Patent Fresh Water Apparatus for Ships' Use.

This apparatus is designed for the distillation of Fresh from Salt Water; and on long voyages, and where the supply of water is scanty, it will be found invaluable. Testimonials may be seen.

Patent Steam Pump and Fire-Engine for Ships' Use.

This Steam-pump occupies but a small space; works perfectly noiselessly, and throws an immense volume of water. An Illustrated Circular of Fresh Water Apparatus and Steam-pump combined, free on application.

How's Patent Machine for Cutting Bolts, Rods, Spindles, Wire, &c.

Simple in construction, inexpensive, occupies but little space, and will not easily get out of order.

A Pamphlet Illustrative of the above, sent free by post, on application to

A. P. HOW, ENGINEER,

81 MARK LANE, LONDON.

EVERY DESCRIPTION OF ENGINEERS' TOOLS, ENGINE ROOM STORES, &c., &c., SUPPLIED. (38)

SCOTT'S

PATENT GRASS SEED SEPARATOR,

which entirely extracts the Seeds of "COUCH," "TWITCH," "SPEAR," or "HAIR" GRASS, and other impurities from

PERENNIAL AND ITALIAN RYE-GRASS, &c.,

AND

SCOTT'S PATENT CARROT SEED BEARDING

AND

CLOVER AND TREFOIL MILLING OR DRAWING MACHINE,

which effectually removes the beard from Carrot Seed, rendering it fit for sowing with facility by drill or otherwise, and by the separation of abortive or diseased grains vastly increases its vegetative per centage. By a slight modification it is applicable to the other purposes before mentioned.

These Machines were admittedly the most novel, and, at the same time, the most useful and important to the Farmer of any exhibited at the late SMITHFIELD CLUB SHOW.

They may be seen at work at the Establishment of the Manufacturer,

Mr. T. MIDDLETON, Engineer, Southwark.

Communications to be sent to the Patentee, J. SCOTT, 111 Drummond Street, Euston Square, London, N.W. (43.)

THE ROYAL AGRICULTURAL SOCIETY OF ENGLAND'S FIRST PRIZE REAPER.

BURGESS & KEY, PATENTEES AND SOLE MAKERS, 95 NEWGATE STREET, LONDON.

MANUFACTORY, BRENTWOOD, ESSEX.

BURGESS & KEY'S extensive Manufactory is wholly occupied in the Manufacture of

REAPING MACHINES AND GRASS MOWING MACHINES,

upon which they have concentrated their efforts since the year 1851. Their practical experience enables them to produce a Reaping Machine which can be depended on by the Farmer.

Owing to the excessive demand for last season, many orders were left unexecuted. BURGESS & KEY therefore earnestly request that orders for next season (1859) be sent as soon as possible, otherwise they cannot guarantee to deliver in time.

Price £12 10s. Net Cash, at the Works, complete with Conical Screw Divider for long Grain; without the Conical Screw, £40. Extra Knife, £1 5s. If other extras are supplied they are charged for. A man sent to start the Machine, if required, on payment of his expenses.

BURGESS AND KEY'S GRASS-MOWING MACHINE

(ALLEN'S AMERICAN PATENT).

Before introducing this Machine to the English public, BURGESS & KEY determined to fully test its capabilities, and the all-important point—durability. One Machine cut, on the farm of Mr. C. Hall, Havering, Romford, Essex, 83 acres Grass; and the same Machine afterwards cut, on the farm of Mr. Tabrum, Bovis Hall, near Brentwood, Essex, 100 acres Grass, and 20 acres Clover. The work done was declared to be better and lower than the scythe, and at the rate of 1 acre per hour. Orders have been received from both those Gentlemen, and numerous others, for Machines for next season. Price £30.

BURGESS & KEY'S Manufactory is entirely devoted to REAPING MACHINES and MOWING MACHINES.

95 NEWGATE STREET, LONDON.—MANUFACTORY, BRENTWOOD, ESSEX.

FURTHER PARTICULARS AND CATALOGUES SENT ON APPLICATION. (39)

Under the Patronage of the Board of Admiralty.

SHIPS' PUMPS OF HER MAJESTY'S NAVY.

JOSIAH STONE,

SOLE MANUFACTURER OF

DOWNTON'S WELL-KNOWN AND MUCH APPROVED

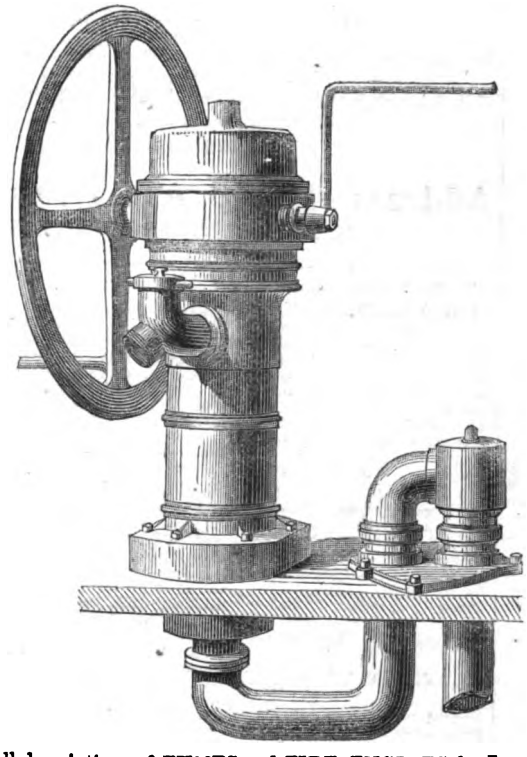
Ships' Pumps,

Which have been used in preference to all others on board the vessels

OF HER MAJESTY'S NAVY,

For upwards of thirty years, and have given the greatest satisfaction, effectually answering all the purposes required of any Ships' Pumps, and capable of throwing most powerful jets of water in case of fire.

These Pumps have also been most extensively used on board merchant vessels, both at home and abroad, and have been supplied to the Royal Navies of France, Prussia, Holland, Russia, Spain, and Turkey. The Pumps are portable, as they may be easily removed from the ship and put to work in a boat alongside in a few minutes. Each pump is fitted with a large foot valve plate (which may be placed in any part of the vessel most convenient), and from which communication is made to any number of distinct compartments in the vessel. In case of any of these pipes fouling, the water, by an almost momentary attachment, may be forced from the Pump downwards, so as to clear all obstructions, preventing any possibility of stoppage. The valves are of the simplest description, and being faced with ordinary leather discs, the latter may be renewed in a few minutes by the most inexperienced hands. By the peculiar construction of these Pumps, a most perfect and uninterrupted flow of water may be maintained; so uniform as to be undistinguishable from that proceeding from a cistern. The Pumps are made of several sizes, those of 7, 9, and 12 inches bore being most generally used. They may, however, be ordered of any dimensions required, and may be fitted either with one or two fly wheels. A standard, &c., is also supplied with these Pumps, to enable them, when necessary, to be used as ordinary hand-lever pumps.



JOSIAH STONE, Engineer, Manufacturer of all descriptions of PUMPS and FIRE ENGINES for Land and Ships' Use; Brass and Iron Founder and Finisher, Nail and Rivet Maker, &c.

CONTRACTORS FOR FIRE-ENGINES, ETC., TO THE WAR DEPARTMENT,

RAILWAY STATION, DEPTFORD, AND 12 GARLICK HILL, CITY, E.C.

ARTESIAN WELLS, BORING TOOLS, PUMPS, &c. Engineers, Architects, Surveyors, Builders or others requiring a good supply of Water may have any quantity procured by W. SPELLER, 14 York-street, Blackfriars'-road, London, where may be had any quantity of Tools for Sinking or Boring, from 2 to 20 inches diameter, and from 100 to 2,000 feet depth; also Men and Tools to bore for Railroads, Minerals, &c., in any part of the world. Boring Tools and suitable Pipes for exportation, with full instructions for their use.

Builders, Contractors, Brickmakers, Barge and Ship Builders, and others, can be supplied with Wrought or Cast Iron Pumps, Double or Single, for excavation of Deep Wells, from 3 to 14 inches in the bore, and from 6 to 130 feet in length, to work by Hand or Steam Power.

Hot-water Apparatus for Conservatories, &c., on the most economical and improved principles.

THE CONSTRUCTION OF WROUGHT IRON BRIDGES; embracing the Practical Application of the Principles of Mechanics to Wrought Iron Girder Work. By JOHN HERBERT LATHAM, M.A., Civil Engineer, Fellow of Clare College, Cambridge.
Cambridge: MACMILLAN & Co., and 23 Henrietta-street, Covent-garden, London.
From the DERBY MERCURY.
"A very valuable and interesting work. . . . . The practical and scientific man will be able to judge of its importance when we say that the promises held out in the preface are fulfilled in the most painstaking, clear, and accurate manner. To the professional man we should imagine Mr. Latham will have rendered valuable service by this book, which is not without scraps of information interesting to the most uninitiated of readers. . . . . We have no hesitation in saying that it is a work of the greatest value, not only to professional men, as an aid to practice, but to the world at large, as tending to reduce the science to mathematical accuracy, and so lessen the chance of accident." (88)

HOBBS'S LOCKS.

The attention of Architects and Builders is respectfully invited to
HOBBS'S NEW MORTISE LOCKS,
Which are now manufactured by PATENT STEAM MACHINERY, and, while superior to any other locks in the market, are sold at a price which defies competition. The Plates are made of number "Twelve Gauge" Iron, and being so thick, the pins cannot be loosened by the constant jarring of the door. The security consists in four double-acting levers, while, to secure unusual freedom of motion and prevent the wear of the parts,
HOBBS'S PATENT FRICTIONLESS FOLLOWER
Is also applied. The retail price of these Locks is 10s., from which a liberal discount is allowed to the trade.
HOBBS'S NEW MORTISE LOCKING LATCHES FOR STREET DOORS,
Price 18s. And
HOBBS'S NIGHT LATCHES, RIM OR FLUSH, PRICE 10s.,
Are also recommended, together with every description of Lock required for house and cabinet work. Lists of Prices will be forwarded on application, post free.
N.B.—A complete Assortment of FIRE and BURGLAR-PROOF SAFES (Milner's Patent), fitted with HOBBS'S PATENT PROTECTOR LOCK, POWDER-PROOF.
ALSO, STRONG-ROOM DOORS, CASH AND DEED BOXES, ETC.
Address—Hobbs, Ashley, and Co., 76 Cheapside, E.C.
MANUFACTORY, ARLINGTON STREET, NEW NORTH ROAD.
(86)

TO ENGINEERS' TOOL MAKERS, AND OTHERS.

THE ADVERTISER is desirous of meeting with an engagement as TOWN or DISTRICT AGENT for an Engineers' Tool Maker, or firm whose business lies amongst Engineers and practical men. He is an Engineer by profession, has for many years been engaged in bringing into operation several inventions, and can give unexceptionable references. A very moderate fixed salary only expected. Address M. C., MECHANICS' MAGAZINE Office, 166 Fleet-street. (78)

PUMPING MACHINERY.

GWYNNE AND Co., Engineers, London, manufacture and supply the following Machinery, of the most approved construction and with all the latest improvements:—Portable and Fixed Steam-Engines and Boilers of every description; Waterwheels, Windmills, Horse and Hand-power Machines; Pumping Machinery for the Supply of Towns, Cities, and Districts, and for the Irrigation of Coffee, Cotton, Indigo, Sugar-cane, and Rice Estates, for pumping out Coffer-dams, Canals, Dry Docks, Reservoirs, &c. They also manufacture and supply the Pumping and other Machinery for Paper, Pulp, and Fulling Mills, Breweries, Distilleries, Tanneries, Starch Works, Bleaching, Dyeing, and Calico Printing Works, Chemical Works, Silk, Cotton, and Flax Mills, and Manufactories in general. All Letters not paid will be refused. Illustrated Price Lists forwarded on receipt of Six Postage Stamps. —GWYNNE AND Co., Hydraulic and Mechanical Engineers, Essex-wharf, Strand, London.
For Exportation.—The above can be obtained through British Merchants, Shippers, and Colonial Agents. (24

HIGH-PRESSURE VALVE-COCKS, LAMBERT'S PATENT.

Equilibrium Ball Valve. Cottage Closet Valve.

The Equilibrium Ball-Valve is simple and certain in its action, and is cheaper than the common cocks now in use.
The Cottage Valves are suitable for application to any kind of basin; and, as they shut against the pressure, no concussion in the pipes can possibly occur.
These cocks have been extensively and most successfully used in many towns, under continuous high pressure, varying from 100 to 350 feet; their efficiency and durability is, by experience, established.
THOMAS LAMBERT and SON,
Brass Founders, Short-street, New-cut, Lambeth. (80)

TO BRASS-FOUNDERS, ENGINEERS, &c.

THE PATENT PLUMBAGO CRUCIBLE COMPANY having completed the enlargement of their premises, beg to call the attention of all users and shippers of Melting Pots to the great superiority of the PATENT CRUCIBLES, which have been used during the last three years by some of the largest melters in England and abroad. In addition to their capabilities of melting an average of from thirty-five to forty pourings; they are unaffected by change of temperature, never crack, but can be used till worn out, requiring only one annealing for several days' work, and become heated much more rapidly than ordinary pots, effecting thereby a saving of more than fifty per cent. in time, labour, fuel, and waste. The Patent Plumbago Crucible Company also manufacture and import clay crucibles, muffles, portable furnaces, sublimate pans and covers, glass-pots, all descriptions of fire-standing goods, and every requisite for the assayer and dentists. For Lists, Testimonials, &c., apply to Battersea Works, London, &c. (43

LIST OF MISCELLANEOUS TENDERS INVITED, AND ENGAGEMENTS OPEN.

RAILWAY WORKS, *Limerick and Castle Connell Railway.*—The directors of this Company advertise for tenders for the construction of their line from Castle Connell to Killaloe. Plans, &c., at the Engineer's office, 51 George-street, Limerick. Mr. E. W. Maunsell, the Secretary of the Company, will receive sealed tenders at 1 Upper Hartstoye-street, Limerick, on or before the 1st of Feb.

DOCK AND RAILWAY, *Penarth.*—The Penarth Harbour, Dock and Railway Directors solicit tenders for the construction of the Dock at Penarth, and a portion of railway leading thereto. Plans, &c., on and after Jan. 24, at Mr. Hawkshaw's office, 33 Great George-street, Westminster. The directors will meet at their offices in Cardiff at ten on Feb. 12, to receive the tenders. Secretary, Mr. Booth Bacon.

ERECTION OF A JETTY, *War Department.*—Up to the 17th inst. tenders will be received at the office of the Director of Contracts, War Department, Pall-mall, for the erection of a jetty at the Powder Magazine, Bull Point, Plymouth. Drawings, &c., at the War Office, Whitehall, or at the Royal Engineer Office, Devonport.

DRAINAGE PLANS, *Bicester.*—The Local Board for the parish of Bicester, in Oxfordshire, are ready to receive tenders for preparing the necessary plans and estimating the cost of drainage of the town of Bicester. The tenders, with references to the competency and experience of the persons making them to be delivered on or before Feb. 5, to Mr. George Cannold, Clerk to the Board.

MARINE WORKS, *Swansea.*—Specifications and plans for the construction of a battery and other buildings on the Light House Island, Mumbles, in the Swansea Bay, may be seen at the Royal Engineers' Office, Pembroke Dock, by whom tenders will be received to the 20th January.

ROADS, *Hull.*—Tenders are invited for the repairs of the roads and footways within the borough of Hull, from March, 1859, to June 30, 1860. Specification on application to Mr. R. A. Sharliker, Surveyor, 73 Lowgate-st. Hull.

NEW PUBLIC BATHS, *Birmingham.*—The Baths and Parks Committee of the Birmingham Town Council are prepared to receive tenders for the erection of baths in Woodcock-street in that town. Drawings, &c., at the office of the architect, Mr. Edward Holmes, 25 Temple-row, Birmingham, to whom builders wishing to compete were requested to send their names by the 12th inst. Tenders to be sent to the Town Clerk (Thos. Stanbridge, Esq.), on or before the 29th inst., and to be accompanied with the names of two sureties for at least one-fourth of the tender.

BUILDINGS, &c., *Bishopstone.*—Tenders are requested for the new buildings and works on the estate of the Ecclesiastical Commissioners at Bishopstone, Wilts, near Shrivenham, on the line of the Great Western Railway. The works will be commenced so soon as the weather permits. Two sureties will be required for three-fourths of the tender. Drawings, &c., at the offices of Messrs. R. J. and H. Cluton, 9 Whitehall-place, Westminster, or at the residence, at Bishopstone, of Mr. Hodge. Tenders to Messrs. Cluton, on or before Feb. 5.

VICARAGE AND SCHOOLS, *Portsmouth.*—Mr. C. E. Davis, F.S.A., of 3 Westgate Buildings, Bath; or the Rev. Thos. Baugh, vicar of Catherington, near Portsmouth, Hants, will both show the plans and quantities necessary to the erection of a vicarage house and other buildings at Catherington; and Horndian Church of England Schools, also in the parish of Catherington, for each of which separate erection tenders are invited, that must be delivered at 3 Westgate-buildings, Bath, not later than January 20.

RAGGED SCHOOLS, *Nottingham.*—Tenders are invited until Feb. 4 for the erection and complete finishing of Ragged Schools in Nottingham. Drawings, &c., at the office of Mr. Charles Wright Edwards, 4 St. James's-terrace, Camden-town, London.

COPPER, *Navy.*—The Board of Admiralty invite tenders to Jan. 18 for the supply of 100 tons of tough-cake copper at Chatham Dockyard.

CONSTRUCTION OF AN EMBANKMENT.—*River Shannon.*—Tenders are wanted from persons willing to construct an embankment on the foreshore of the river Shannon, adjoining the lands of Shannon Grove, the estate of C. Brinsley Marlay, Esq., in the parish of Ardkenney, Barony of Kenry and county of Limerick, according to plans and specifications to be seen at the office of Mr. W. F. Irwin, Land Improvement Department, Custom House, Dublin, and at Mr. Cruise's Hotel, Limerick. The contractor must give two solvent securities to the amount of £2,500, for the due fulfilment of the contract within such time as may be agreed upon. Application to be made, and proposals forwarded to Mr. Wm. Featherstonhaugh, Carrick, Mullingar, up to the 1st of February.

COALS, *Navy.*—The Admiralty Commissioners will be ready at two o'clock on the 8th February, to treat with such persons as may be willing to contract for supplying and delivering into store at Ascension, 3,500 tons of South Wales coals, fit for the service of Her Majesty's steam vessels. Conditions and a form of tender to be had at the office of the Storekeeper General of the Navy, Somerset Place. No tenders after two o'clock on the day named; and principals or agents to be present. Every tender to be addressed to the Secretary of the Admiralty, to have "Tender for Coals" in the left-hand corner, be delivered at Somerset Place, and be accompanied by a letter signed by two responsible persons engaging to become bound with the person tendering for £3,000.

SWINGING LAMPS AND MESS UTENSILS, *Navy.*—At half-past one o'clock on the 18th instant, the Admiralty Commissioners will be ready to treat with persons willing to contract for supplying and delivering into Her Majesty's Transport Stores at Deptford, all such quantities of swinging lamps, knives, forks, spoons, bowls, plates, dishes, &c., as shall from time to time be demanded under a contract 12 months' certain, and afterwards, until the expiration of three months' warning. Patterns of the articles and the conditions of the revised contract at the Office, in Somerset Place, of the Comptroller for Victualling and Transport service. All tenders must be on the printed form to be supplied, and must be delivered by the hour named, at Somerset Place, addressed to the Secretary of the Admiralty, and have on the left hand corner "Tender for Swinging Lamps and Mess Utensils."

ELM TIMBER, *Navy.*—The Admiralty Commissioners will be ready on the 1st of February, at two o'clock, to treat with persons willing to contract for supplying Her Majesty's Dockyards with 4,000 loads of English Elm Timber, felled between the middle of November last and the end of February next, and to be delivered (at prices including all carriage and other expenses) by the 30th November, 1859. Tenders may be made for supplying of one or any more of the yards, or for the whole of them. A form of tender showing the distribution and conditions of the contract may be obtained at the Office of the Storekeeper General of the Navy, Somerset Place. No tender will be received after the hour named, and principals or agents duly authorised in writing must attend. Tenders must be addressed to the Secretary of the Admiralty, be duly endorsed, and to be accompanied with the engagement of two persons willing to be bound with the person tendering to the extent of £1 a load.

STEAM ENGINE.—The Bristol Water Works Company are desirous to obtain a new or second-hand steam engine, horizontal or cross-head, of 25 to 35 horse power, intended for pumping. Price and particulars to be forwarded to the Secretary, Mr. Chas. Wm. Bragge, at the Bristol Water Works Office.

ROAD SURVEYORS.—The Stow and Moreton United Trust of Turnpike Roads want a general superintending surveyor, who will be required to keep a horse and reside at Stow-on-the-Wold, Gloucestershire. Salary, £150; to undertake no other business. Qualifications and testimonials to be sent in to Mr. Brookes, the Clerk to the Trustees, at Stow-on-the-Wold, on or before the 20th of January. The candidates to attend at the Unicorn Inn, Stow-on-the-Wold, at 12 at noon, on the 27th inst., when the appointment will be made.

VILLAS, *Upper Norwood.*—Persons are solicited to contract for the building and finishing complete of two semi-detached villas at Upper Norwood, each house to contain six rooms 17 ft. by 16 ft., with attic; hall, 8 ft. 10 in.; elevation, 9, 11, and 10 ft. Bricks are provided but to be carted by the contractor, from the Jolly Sailor, Norwood. Payment to be taken in two London leasehold houses, one let at £40 lease from the Trinity Corporation, at £3 ground rent, having about seventy years to run. The other let at £28 per annum, in the best part of the Grange-road, Bermondsey, under lease at £5 ground rent, having about 80 years to run. Both houses to be finished by September, 1852. Application by prepaid letter to Mr. Hopcroft, printer, 1 Mincing-lane, with initials in left hand corner, "J. J. B."

SCAVENGING, *Paddington.*—The Vestry of Paddington invite tenders for carting away the street slop, from Lady-day, 1859, to Lady-day, 1860. Tenders are also invited for watering the parish roads twice a day (except Sundays), from the 1st of March next to the 15th of October following, the Vestry to find the water. Tenders may apply either to the whole parish or to two divisions, to be addressed to "The Vestry," at the Vestry-hall, Harrow-road, on or before the 31st January; and all persons tendering to be there at ten on the following morning prepared with the names of two sureties, or their proposals will not be considered. Particulars of the roads, with printed forms of tender, which are indispensable, on and after the 17th inst., at the Vestry-clerk's office, between 10 and 4. The expenses of the contracts and bonds to be paid by the contractors.

BUILDING ADDITIONS AND ALTERATIONS, *Galway.*—Tenders are sought from persons willing to make additions and alterations to Rychill House, near Monivea, in the county of Galway, according to plans and specifications which may be seen on application to Stephen Roche, Esq., Rychill, Monivea; or at the office of J. F. Kempster, Esq., Architect, Ballinasloe. Tenders to be sent to Mr. Roche on or before the 1st of February.

GAS WORKS, *Dublin.*—The directors of the Government Independent Gas Consumers' Company are desirous of receiving tenders for the erection of Retort Houses, Coal Stores, Purifying House and other buildings, upon their works, 74 Sir John Rogerson's Quay, according to drawings and specifications to be seen at the office, No. 5 Dame-street, on and after Monday, January 17th. Tenders to be forwarded to Mr. George Flintoff, secretary to the Company, not later than January 27th, at noon.

FIFTY COTTAGES, *Blyth.*—The proprietors of Cowpen Colliery, Blyth, are willing to let the building of fifty cottages at that colliery. Plans and specifications at the office of the colliery.

PAVING WORKS, *Tynemouth.*—The Tynemouth Local Board of Health invite tenders for paving works required within the Borough during the present year. Specimens may be seen and information obtained at the office of the Borough Surveyor, Norfolk-street. Tenders will be seen at the Town Clerk's Office, Howard-street, not later than the 19th inst.

CANVAS FOR PACKING, *East India Board.*—The India Finance Home and General Works Committee, give notice that they will be ready on or before the 25th inst., to receive proposals from persons willing to supply canvas for packing; and that the conditions of the contract may be had at the Secretariat Office, where the proposals are to be left any time before 11 in the forenoon of the 25th of January, after which no tenders will be received.

GOODS AND STORES, *Port of Sunderland.*—The Commissioners of the River Wear are prepared to receive tenders for the ensuing year's supply of malleable and cast iron, brass casts, nails, oils, tallow, white lead and paints, hempen rope (tarred and white) and coir warps and tawlings.

GAS PIPES, *Walsall.*—The Walsall Improvement Commissioners are ready to receive tenders for a further supply of 3, 4, 5, and 6-inch cast-iron turned and bored socket pipes, delivered at their gas works. Sealed tenders, marked "Tenders for gas-pipes," stating the price and weight per yard, to be sent to the Commissioners' Clerk's office, on or before Thursday, the 20th of January instant.

CAST STEEL FILES, &c., *India Board.*—The Finance, Home, and Public Works Committee give notice that the will be ready, on or before Friday, the 21st instant, to receive proposals in writing, sealed up, from such persons as may be willing to supply cast steel files, rasps, and rubbers; and that the conditions of the said contract may be had on application at the Secretariat Office, where the proposals are to be left any time before eleven o'clock in the forenoon of the said 21st day of January, 1859, after which hour no tender will be received.

STONE AND BRICKS, *Wolverhampton.*—The Wolverhampton town council are prepared to receive tenders for supplying them with rowley rag and other stone and bricks, for one year, to be delivered at their wharf in the borough, the tenders to be in the following form:—Rough stone, broken rag stone, randoms, six-inch squares, four and five-inch squares, three-inch squares, all at per ton, delivered; bricks—best common blue, plain barn floor, chequered ditto, all at per 1000, delivered. The tender for bricks must be accompanied by samples. The town council do not bind themselves to accept the lowest or any tender. Tenders must be sent to Mr. Parnell, borough surveyor, on or before Saturday, January 22, 1859, marked "Tender for stone and bricks."

ARCHITECTS' COMPETITIONS. *Cemetery Chapels.*—Detailed plans and elevations are required by the Burial Board of Oakham, in the county of Rutland, accompanied by specifications and estimates for erecting two chapels, connected externally as one building, and also an entrance lodge with board-room in it; the plans are also to include entrance gates, boundary fencing, and the draining and the laying out of the grounds, 4½ acres in extent. A premium of £30 will be given for the approved designs, which the board will keep, returning the unsuccessful; but the board do not bind themselves to employ the architect of the approved plan to carry out the works, nor do they undertake to accept any plan. Information will be given by Mr. Alfred Ellingworth, the clerk to the board, to whom the plans must be sent on or before Feb. 8.——*Monuments.*—Designs for a monument to be erected in the Mowbray Park, Sunderland, to the late General Sir Henry Havelock, at a cost exceeding £1,600, are solicited by the committee appointed by the promoters of the movement. Further information will be given by the Hon. Secs. Messrs. E. T. Gourley and Wm. Snowball; and the designs must be sent to the Mayor of Sunderland, on or before the 7th of Feb.——A monument upon which it is hoped by the promoters that they will be able to expend from £400 to £500, and towards which £345 has been already subscribed, is proposed to be erected on Hatherleigh Moor, Devonshire, to the memory of the late Lieut.-Col. Harris, C.B. The erection committee invite designs or models to be delivered for them before Thursday, Jan. 20, to the care of Mr. Pearse, Solicitor, Hatherleigh. On that day, at one o'clock, the committee will meet at the Subscription Rooms, Hatherleigh, to decide upon the designs or models sent in, for none of which, however, are they to be held liable to pay.——The Police Committee of the Loughborough Magistrates are prepared to spend not more than £1,600 on a Police Station there. The proposed site contains an area of 1,011 square yards, belongs to the Town Hall Directors, has a frontage to Wood Gate, and extends thence back to the Town Hall, and lies within a few yards of the Market-place, whence to the new building there will be access by a road to be secured. The building must comprise a police station with eight cells; house for superintendent; house for serjeant of police; a room for stamping weights and measures; and a cart-house and stable. Also a room for magistrates' meetings, 40ft. by 20ft., with retiring room, clerk's office, and room for witnesses in attendance. A plan of the ground, &c., may be inspected at the office of the Clerk of the Peace, New street, Leicester, and at the Magistrate's Clerk's Office, Loughborough; to which latter place plans must be sent by the 24th January.——Premiums of £50, £30, and £20 respectively are offered for plans or models of a new Tabernacle for the congregation of the Rev. C. H. Spurgeon, on land situated near the Elephant and Castle, Newington. Every cost, including architect's commission, to be about £16,000. Gothic designs will not be accepted, and the plan of the Surrey Music Hall, because of its acoustic excellence, decidedly preferred. The drawings to show a plan of each floor and gallery—longitudinal and transverse sections—and elevations drawn to a scale of eight feet to the inch, and tinted in light brown Indian ink. One perspective view tinted in like manner may accompany each design; but bird's-eye perspective views and drawings in frames (other than straining frames) and glasses, will not be received. The building to contain, on the basement floor (which is to be five feet below the level of the footway), school-rooms, 12ft. high, for boys and girls, and lecture-hall, to seat 800 persons. The chapel above to seat 3,000 persons, and standing room for not less than 1,000, and with not more than two tiers of galleries; each sitting to be not less than 2ft. 6in. by 1ft. 7in. Provision to be made for baptistry, six vestries, water-closets, urinals, &c. Each architect to state the commission he will require on outlay—such commission to include all expenses for measuring, superintendence, &c. The architects who compete will be requested to be the judges of the plans, and to award the first and third premiums. For this purpose the committee will require the name and address of each competitor to be forwarded to them by post on the 1st day of February. No architect will be allowed to select his own design. The designs must be sent in by Jan. 31.

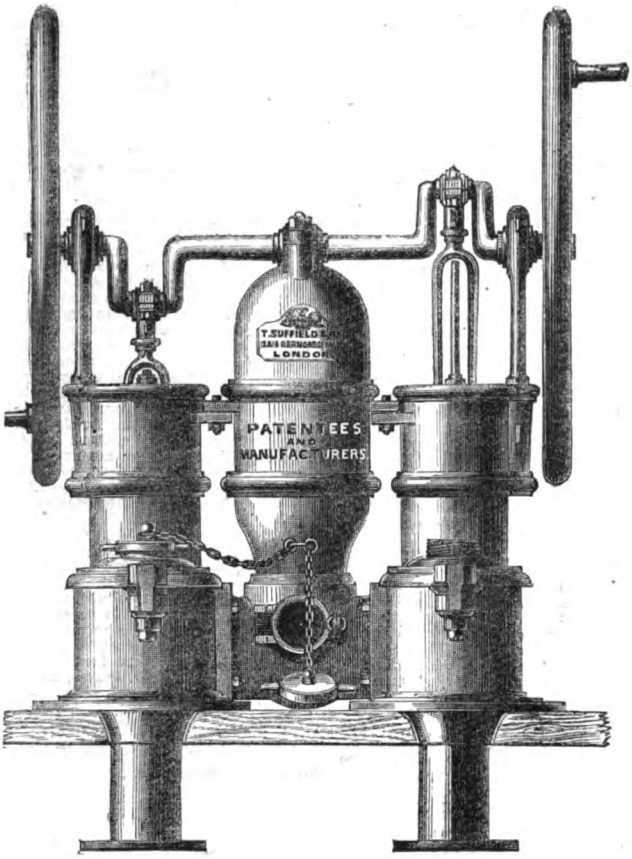
T. SUFFIELD AND CO.

Call the particular attention of

SHIP-OWNERS, SHIP-BUILDERS, AND COMMANDERS OF STEAM AND SAILING VESSELS,

to the Simple and Efficient Arrangements of their

PATENT PUMPS.



Ships' Pumps

AND

Fire Engines,

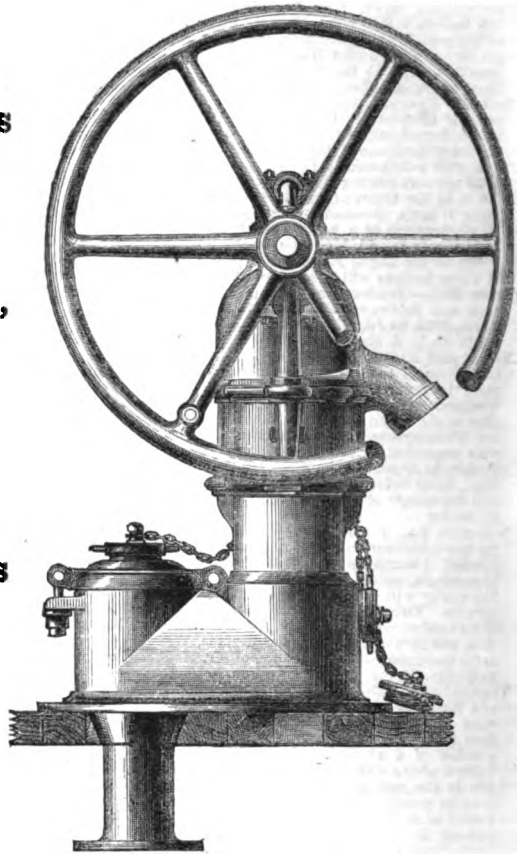
Fixed and Portable.

WITH

Patent Valves

AND OTHER

Improvements.



These Pumps are free from that liability to choke which is common to other Pumps, and their Working Parts are not susceptible of derangement either from wear or from being long out of use. They pass entirely through them, with ease, any substance that may enter the Suction Pipes. The Novelties in these Pumps are their adaptation to the varied duties of Ships' Pumps, the facilities they afford for Cleansing the Suction Pipes, and for Sounding or Examining the Valves; the readiness with which they may be used for Ventilating the Bilge, or for acting as a Syphon either for Watering the Ship, or for extinguishing Accidental Fires on board; the rapidity with which they can be converted into Fire Pumps, or be applied to the Washing of Decks; and their capability of Pumping from Several Compartments.

T. SUFFIELD AND CO.

Also respectfully solicit the attention of STEAM SHIP BUILDERS and OWNERS to their Large and Varied STOCK of

ASSORTED STORES FOR MARINE PURPOSES.

They keep a Large Stock of Goods, of their own Manufacture and from the Best Makers, constantly on view; so that by a visit to their Works or Depôt, much valuable time may be saved by Managers, Engineers, and other Gentlemen who may require such Stores, together with a further saving in the cost of such Articles.

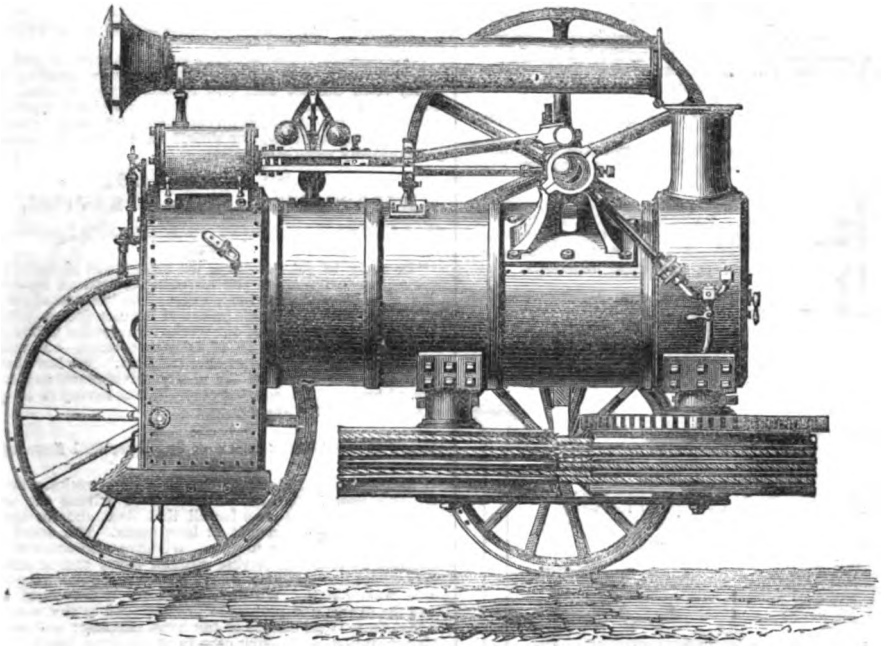
COLLINSON HALL'S PATENT WINDLASS

AND

STEAM PLOUGH AND IMPLEMENT GEAR.



The object of this mechanism is to render effective the WHOLE POWER of engines used in drawing ploughs or other implements in tilling land. This is accomplished by carrying the wire rope, in the form of the figure 8 round horizontal drums fixed (so as to be easily removable) under the engines. By this arrangement the evils arising from overlaying the coils of rope when wound upon the capstan principle are avoided, as also are those arising from an unequal wear of the ordinary horizontal pulleys. In the new arrangement the solid drum is constructed with several grooves, while the other is composed of as many independent pulleys as there are grooves in the drum. The upper or lower pulley, as the case may be, revolves in one direction, while the remaining ones revolve in the opposite direction. The solid drum only is driven directly by the engine, while the pulleys revolve by frictional contact, and thus all slipping is avoided.

The simplicity of this Gear is one of its chief recommendations, little or no framing being required. The axes being bolted to the bottom of the boiler, a simple rod or beam retains them in a vertical position. The Gear may be fitted and again unshipped from an engine (by means of keys through the axes, by which the Gear is retained in place) in less than ten minutes.

APPLICATIONS FOR LICENCES TO BE MADE TO

COLLINSON HALL, PRINCES GATE, ROMFORD, ESSEX.

THE LONDON

WARMING AND VENTILATING COMPANY,

(LIMITED,)

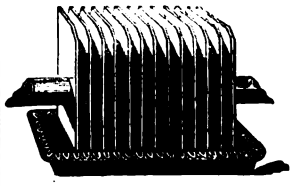
36 GREAT GEORGE STREET, Westminster, S.W.

(MANAGER—Mr. WOODCOCK.)

Churches, Greenhouses, Offices, and Buildings of every description warmed by means of a modification of the plan successfully used during the last five years by Mr. Goldsworthy Gurney in both Houses of Parliament.

Steam, Hot-water, Gas, and in open or enclosed fireplaces, Coal and Coke are equally available for the process.

The cost is less and the effect greater than that of any other known means.



The Horticulturist will find herein an instrument of new and important powers.

The apparatus may be seen in ST. PAUL'S CATHEDRAL, the various offices of the "Department of Science and Art," and in many churches and other buildings.

Particulars and Testimonials forwarded on application.

CLAYTON, SHUTTLEWORTH, AND CO.,

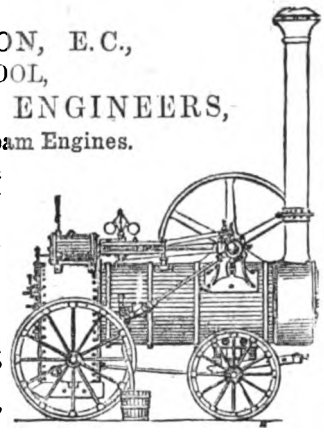
OF LINCOLN,

78 LOMBARD STREET, LONDON, E.C.,

AND 36 DALE STREET, LIVERPOOL,

AGRICULTURAL AND GENERAL ENGINEERS,

And Manufacturers of Portable and Fixed Steam Engines.



Combined Threshing Machines, which dress the corn ready for market at one operation. Grinding Mills, Saw Benches, Pumps for Irrigation and Mining purposes, with all necessary gearing for being driven by steam power. Full particulars and estimates given on application to the above address.

C. S. and Co.'s PORTABLE STEAM ENGINES are adapted for every purpose to which steam-power can be applied. When intended for winding, they are fitted with reversible link motion and winding gear. They are easy of removal, as may be seen by the engraving, and can be set to work immediately on arrival.

C. S. and Co. are now doing an extensive foreign and colonial business, and are prepared to send off engines and machinery of the before-mentioned kinds in a few days from the date of order. They would also call attention to the important *reduction in prices* made for the new year.

For Exportation.—The above can be obtained through British Merchants, Shippers, and Colonial Agents. (23)

IMPROVED MACHINERY FOR AGRICULTURISTS.

RICHARD GARRETT & SONS,

LEISTON WORKS, SAXMUNDHAM, SUFFOLK,

(ESTABLISHED A.D. 1778),

EARNESTLY solicit the continued support of their numerous Friends, Agriculturists, Shippers, and others; the additions made to their Works during the present year, in the erection of new sets of Workshops, fitted with the best mechanical appliances for producing Machinery of the most improved construction, expeditiously and economically, justifies their soliciting increased support, while their leading reputation as Inventors and Manufacturers of FIRST CLASS Agricultural Machinery, is a sufficient guarantee that every Machine supplied from Leiston Works will prove to the entire satisfaction of the purchaser.

R. G. & S. are now manufacturing the following Machines and Implements, which they guarantee to be thoroughly efficient in every respect:—

PORTABLE AND FIXED STEAM ENGINES. } From 4 to 40 Horse Power, suited for every kind of work
SELF-PROPELLING AND TRACTION ENGINES. } to which Steam Power is applied.
STONE GRINDING MILLS.
MORTAR AND PUG MILLS.
MILLWRIGHTS' WORK of all kinds.
SAWING MACHINERY, from 4 to 20 Horse Power.
BRICK AND TILE MACHINES.

IMPROVED SETS OF FARM MACHINERY, for Large Occupations.
PORTABLE AND FIXED MACHINERY, for Thrashing and Dressing Corn.
THE PRIZE BOLTING AND OPEN-DRUM HORSE-POWER THRASHING MACHINES.
CORN DRESSING MACHINES, for Hand, Horse, Water, and Steam Power.
BARLEY AVELLING MACHINES.
CHAFF CUTTERS, for Hand, Horse, Water, and Steam Power.
PATENT TURNIP CUTTING AND PULPING MACHINES.

THE PRIZE CORN AND SEED DRILLS.
PRIZE CORN AND SEED DRILLS WITH MANURE APPARATUS.
PRIZE SEED AND MANURE DRILLS.
LIQUID, SEED, AND MANURE DROP DRILLS.
CHAMBER'S PATENT BROADCAST MANURE DISTRIBUTOR.
GARRETT'S PATENT HORSE HOE for all Crops.
PATENT REVOLVING HOES for Root Crops.
IMPROVED PLOUGHS AND REAPING MACHINES.
&c. &c. &c.

Of which full detailed particulars will be found in R. G. & SONS' ILLUSTRATED CATALOGUE, sent postage free to any address, in English, French, or German; and any of the above Machines will be shown in operation at R. G. & Sons' Farm, near the Works, on their receiving a few days' notice.

A Copy of R. G. & SONS' new COLONIAL LIST will be forwarded free to any of the Colonies, and Shippers will be supplied with these lists, with their names and addresses printed on, free of charge, by making application for the same.

ADDRESS—R. GARRETT & SONS, LEISTON WORKS, SAXMUNDHAM, SUFFOLK. (57)

IMPORTANT TO MANUFACTURERS MILL OWNERS, &c.

GUTTA PERCHA MILL BANDS.

THE GUTTA PERCHA COMPANY beg to state that the increasing demand for the Gutta Percha Strapping for Driving-bands, Lathe-straps, &c., fully justifies the strong recommendations they have everywhere received.

Their durability and strength—permanent contractability and uniformity of substance—their non-susceptibility of injury from contact with oils, grease, acids, alkalies, or water—and the facility with which the only joint required can be made in bands of from 200 to 300 feet long—render them superior to leather for almost all working purposes, and decidedly more economical.

TESTIMONIALS.

IMPORTANT ANNUAL SAVING.

From TRUMAN, HANBURY, BUXTON, & Co., Brewery, London.

"In reply to your inquiry, we have much pleasure in bearing our testimony to the advantages, both as regards economy and saving of time, effected by the use of your Patent Gutta Percha Bands in lieu of Leather Straps. The stoppage of one portion of our works through the failing of the leather strap used to be of daily occurrence—but with this annoyance we are now never troubled. We have had these straps in operation for nearly three years, and are assured by our Engineer that *they effect a saving to us of at least* THIRTY POUNDS *a year*."

From JAMES ABERNETHY & Co., Fury Hill Foundry Aberdeen.

"We have now had Gutta Percha Bands working here *for three years*. One of them has been driving the fan blast for our smith's shop for all that time, and for anything we see, may drive it as long again. The speed of the fan is but 1,200 per minute. We have used them with complete satisfaction, driving circular saws, and in some cases where leather bands would have been quite inapplicable from damp. We have uniformly endeavoured to have the drums and pulleys so proportioned to the strain, as that there is no chance of the band slipping; and with this precaution, and taking care in using *cross bands that they do not rub*, we are quite satisfied that they are superior in every respect to leather—stronger at the same weight, and keeping quite straight in working—requiring no lacings, and very seldom any repairs."

WATER POISONED BY LEADEN PIPES.

The above engraving represents accurately a section of a leaden pipe, which was employed for a short time in conveying water from a well on the grounds of Mr. Dick, of Bonchurch, Isle of Wight.

POISONED WATER PREVENTABLE

BY THE USE OF GUTTA PERCHA TUBING.

The Gutta Percha Company have been favoured with the following letter,

From Dr. MURRAY, Hull.

"It is impossible to conceive of anything more injurious or destructive to the health of the community than the use of *leaden pipes* for the conveyance of water. The poisonous salts of lead thereby communicated are most insidious and subtle. I hail with gratitude the substitution of Gutta Percha Tubing. I have had the leaden pipe of my own house removed, and its place supplied with one of Gutta Percha Tubing. Nothing can be better. I have also recommended it to others, who have adopted the expedient."

A variety of Gutta Percha Articles, such as Mill Bands, Tubing, Sheet, Soles, Pump Buckets, Bosses, Union Joints, Bottles, Bowls, Flasks, Curtain and Cornice Rings, Solid Frames, Galvanic Batteries, &c., &c.

Are prepared to ESTIMATE FOR and CONSTRUCT BRIDGES, PIERS, JETTIES, &c., in Iron, Wood, or Stone. Also to supply Cranes, Girders, Turntables, and Railway Work and Plant generally. (56)

ENGINEERING AND MECHANICAL DRAWING CLASSES.—Instruction given in Engineering and Mechanical Drawing, comprising the preparation of plans, elevations, and sections of marine and locomotive engines, with the detail and working drawings; also the method of delineating screws, bevel wheels, &c.; orthographical projection, and tinting, shading, and colouring taught.—For prospectuses of the Day and Evening Classes apply to Mr. T. J. HILL, at the offices, 15, Old-street, City-road. (73)

EDWIN JEWITT, ENGRAVER ON WOOD AND DRAFTSMAN, 1 Pickett-place, Strand, near Temple-bar. Engineering, Scientific, and Mechanical Designs accurately engraved. Manufacturers and Tradesmen's Catalogues Illustrated. W.C. (84)

HART & SON, MALLEABLE IRON-FOUNDERS, 4 Vine-street, York-road, Lambeth.

Orders for Malleable Iron Castings executed within a week. (77)

TO MARINE ENGINEERS, OR SHIP-BUILDERS.

THE PROPRIETOR of a VALUABLE PATENT for Double-expansive Marine Engines (by which great economy of space and fuel is obtained) is desirous of entering into arrangements with a respectable firm for the construction of the same. An adequate portion of the patent-right would be assigned by the advertiser to any firm taking the matter up; and he would render all assistance in his power, either in London or elsewhere, amongst ship-owners (to many of whom he is well known), in obtaining contracts, &c. Unexceptionable references given. Address C. E., MECHANICS' MAGAZINE Office, 166, Fleet-street. (76)

NOTICE OF DIVIDEND.

BANK OF DEPOSIT, No. 3 PALL-MALL EAST, LONDON, S.W.—The Warrants for the Half-yearly Interest, at the rate of 5 per Cent. per Annum, on Deposit Accounts, to the 31st December, are ready for delivery, and payable daily between the hours of ten and four.

PETER MORRISON, Managing Director.

10th January, 1859.

Prospectuses and Forms sent free on application. (91)

HALKETT'S GUIDEWAY STEAM AGRICULTURE will be Exhibited at Canning-place, Kensington Toll Gate, South of Kensington Gardens, on Wednesdays, the 9th, 16th, and 23rd of February, and to private view upon previous appointment. By this system, every operation of the Farm is performed by Steam Power, the land largely increased in value, and the cost of cultivation greatly reduced. A paper read before the Society of Arts, illustrations, &c., will be forwarded upon application to the Office, 80 Chancery-lane, W.C. (104)

TO ENGINEERS, ARCHITECTS, PATENT AGENTS, &c.

PHOTOGRAPHS OF THE HIGHEST CLASS and of any size, taken and reproduced at a most moderate rate of charge. Reproductions of faultless accuracy, of Machinery, Models, Drawings, &c. Orders attended to in town and country. Estimates forwarded.

SPENCER, READ, & Co., 4 Agar-street, Strand. W.C. (90)

FURNACE DOORS AND BARS.—Steam increased, fuel saved, and smoke prevented, by the PATENT REGULATING AIR-DOORS. Great economy from using the "Doubly-durable" fire bars.

J. LEE STEVENS, 1 Fish-street-hill, E.C. (87)

FIRE BRICKS.—THE FARNHAM INDESTRUCTIBLE SILICIOUS FIRE BRICKS have been greatly REDUCED in PRICE, and will be delivered at the Nine Elms Station, London, at 90s. per 1,000.—Address, G. H. OGSTON, J. M., Paine's Silica Works, Farnham, Surrey. (35)

VITRIFIED BLUE BRICKS are delivered at the Nine Elms Station, London, at 80s. per 1,000.—Address, G. H. OGSTON, J. M. Paine's Silica Works, Farnham, Surrey. (36)

RAILWAY AXLE-BOXES.

WHEREAS on the 14th December instant, a Verdict was given for the Plaintiff in the action of "Bruff v. Marshall and others," tried before the Lord Chief Justice and a Special Jury at Guildhall, whereby the Patents of the Railway Axle-Box Company were substantiated. NOTICE IS HEREBY GIVEN, that legal proceedings will be instituted against all Manufacturers and others adopting or using any of the Company's Patents, including those of Adams and Richardson, Wrighton, Normanville, Vigurs, McConnell, and Miller, without the Company's express licence in writing. Terms of licenses and other particulars may be obtained from the Manager, Mr. P. M. Parsons, 9 Arthur-street West, London-bridge, E.C.

Dated 22nd December, 1858.

(Signed) E. BENHAM, 18 Essex-street, Strand.
J. HENRY JOHNSON, 47 Lincolns-Inn-Fields.
Joint Solicitors to the Railway Axle-Box Company. (7)

TO ENGINEERS, INVENTORS, AND OTHERS.

WANTED, occasional employment by an expeditious Mechanical Draughtman, who has had considerable experience in assisting inventors in carrying out their plans, and afterwards introducing them to the notice of those willing to take them up. Or the Advertiser would not object to take the charge of a small machine shop or railway work.—Apply to J. J., 171 Strand. (99)

A PRACTICAL ENGINEER is in want of a Situation. Salary or class of employment not so much an object as the probability of a permanency if satisfactory. He is a good Draughtsman, and can produce references.

Address A. B., Albion-chambers, 69A Dean-street, Soho-square, London. (102)

TO ENGINEERS' TOOL MAKERS, AND OTHERS.

THE ADVERTISER is desirous of meeting with an engagement as TOWN or DISTRICT AGENT for an Engineers' Tool Maker, or firm whose business lies amongst Engineers and practical men. He is an Engineer by profession, has for many years been engaged in bringing into operation several inventions, and can give unexceptionable references. A very moderate fixed salary only expected. Address M. C., MECHANICS' MAGAZINE Office, 166 Fleet-street. (78)

SCHOOL FOR MECHANICAL ENGINEERING and SCIENTIFIC EDUCATION, at the College, Chester.

In Addition to English and Mathematics, all the Pupils are taught Drawing suitable for the Architect or Engineer, and in the Laboratory the Principles as well as the Practice of Chemistry.

The use of Tools, the Construction of Machinery, and the Principles of Mechanism may be studied in the various Workshops of the School.

French and German are taught to all who desire it without any extra charge.

Chemical Analyses undertaken, Steam Engines and Machinery examined and reported upon, and Mechanism designed for special purposes. For further particulars apply to the Rev. ARTHUR RIGG, Chester. (95)

WATER GAUGES—WATER GAUGES.—Sir,—We find your German Gauge Tube superior to any other, and strongly recommend it. We were compelled to abandon the use of our water gauge until applying your glass tube.

WILCOX and Co., Millwall Pottery Company.

These Tubes are superior to all others; being a clear white, no mistake can arise in working. Guaranteed to stand a pressure of 500 lb.

Extensively used on all the principal lines.

To be had only of E. MOORE, 55 Upper Marylebone-street, W.; and 72 Great Titchfield-street, W.

*** Price List of Gauge Fittings, &c., on application. (98)

PUMPING MACHINERY.

GWYNNE AND Co., Engineers, London, manufacture and supply the following Machinery, of the most approved construction and with all the latest improvements:—Portable and Fixed Steam-Engines and Boilers of every description; Waterwheels, Windmills, Horse and Hand-power Machines; Pumping Machinery for the Supply of Towns, Cities, and Districts, and for the Irrigation of Coffee, Cotton, Indigo, Sugar-cane, and Rice Estates, for pumping out Coffer-dams, Canals, Dry Docks, Reservoirs, &c. They also manufacture and supply the Pumping and other Machinery for Paper, Pulp, and Fulling Mills, Breweries, Distilleries, Tanneries, Starch Works, Bleaching, Dyeing, and Calico Printing Works, Chemical Works, Silk, Cotton, and Flax Mills, and Manufactories in general. All Letters not paid will be refused. Illustrated Price Lists forwarded on receipt of Six Postage Stamps.—GWYNNE AND Co., Hydraulic and Mechanical Engineers, Essex-wharf, Strand, London.

For Exportation.—The above can be obtained through British Merchants, Shippers, and Colonial Agents. (24

BRICK AND TILE WORKS.

TO BE LET, on Lease or otherwise, with Plant and Clayton's Machine complete, and with immediate possession.

The ground is situated on the east side of London; it contains very superior materials for Bricks and Draining Tiles, and a good supply of water without the cost of pumping. Hack-ground and Drying-sheds spacious and well situated. A railway-siding into the ground, with ample accomodation for making three or four millions per annum. For particulars, apply by letter to C. W., 166 Fleet-street, London, E.C. (17)

TO STEAM SHIP OWNERS, ENGINEERS, AND OTHERS.

How's Patent Steam Engine Counters, can be read at sight.

These Counters register the number of revolutions made by an engine or other mechanism. They may be used for ascertaining the duty of Pumping Engines and Water-wheels; the revolutions on board a steam-vessel; to calculate the slip of the propeller; and in a locomotive to test the slip of the wheels.

How's Patent Salinometer, for Steam Boilers using Salt Water.

By these, the density of the water in the Boiler is at all times accurately shown, and a saving of boiler and fuel is effected. They are adopted by the Admiralty, the Honorable Trinity Corporation, and others. Copies of Testimonials from Messrs. Penn, Messrs. Maudslay, and others, will be forwarded on application.

How's Engine-Room Telegraph, for communicating between Captain and Engineer. Society of Arts Prize Medal, 1855.

This is a Mechanical Telegraph, and by its peculiar construction, error or misunderstanding is rendered impossible. It is now extensively adopted, and gives great satisfaction.

How's Patent Fresh Water Apparatus for Ships' Use.

This apparatus is designed for the distillation of Fresh from Salt Water; and on long voyages, and where the supply of water is scanty, it will be found invaluable. Testimonials may be seen.

Patent Steam Pump and Fire-Engine for Ships' Use.

This Steam-pump occupies but a small space; works perfectly noiselessly, and throws an immense volume of water. An Illustrated Circular of Fresh Water Apparatus and Steam-pump combined, free on application.

How's Patent Machine for Cutting Bolts, Rods, Spindles, Wire, &c.

Simple in construction, inexpensive, occupies but little space, and will not easily get out of order.

A Pamphlet Illustrative of the above, sent free by post, on application to

A. P. HOW, ENGINEER,

81 MARK LANE, LONDON.

EVERY DESCRIPTION OF ENGINEERS' TOOLS, ENGINE ROOM STORES, &c., &c., SUPPLIED. 38)

SCOTT'S

PATENT GRASS SEED SEPARATOR,

which entirely extracts the Seeds of "COUCH," "TWITCH," "SPEAR," or "HAIR" GRASS, and other impurities from

PERENNIAL AND ITALIAN RYE-GRASS, &c.,

AND

SCOTT'S PATENT CARROT SEED BEARDING

AND

CLOVER AND TREFOIL MILLING OR DRAWING MACHINE,

which effectually removes the beard from Carrot Seed, rendering it fit for sowing with facility by drill or otherwise, and by the separation of abortive or diseased grains vastly increases its vegetative per centage. By a slight modification it is applicable to the other purposes before mentioned.

These Machines were admittedly the most novel, and, at the same time, the most useful and important to the Farmer of any exhibited at the late SMITHFIELD CLUB SHOW.

They may be seen at work at the Establishment of the Manufacturer,

Mr. T. MIDDLETON, Engineer, Southwark.

Communications to be sent to the Patentee, J. SCOTT, 111 Drummond Street, Euston Square, London, N.W. (48.)

THE ROYAL AGRICULTURAL SOCIETY OF ENGLAND'S

FIRST PRIZE REAPER.

BURGESS & KEY, PATENTEES AND SOLE MAKERS, 95 NEWGATE STREET, LONDON.

MANUFACTORY, BRENTWOOD, ESSEX.

BURGESS & KEY'S extensive Manufactory is wholly occupied in the Manufacture of

REAPING MACHINES AND GRASS MOWING MACHINES,

upon which they have concentrated their efforts since the year 1851. Their practical experience enables them to produce Reaping Machine which can be depended on by the Farmer.

Owing to the excessive demand for last season, many orders were left unexecuted. BURGESS & KEY therefore earnestly request that orders for next season (1859) be sent as soon as possible, otherwise they cannot guarantee to deliver in time.

Price £42 10s. Net Cash, at the Works, complete with Conical Screw Divider for long Grain; without the Conical Screw, £40. Extra Knife, £1 5s. If other extras are supplied they are charged for. A man sent to start the Machine, if required, on payment of his expenses.

BURGESS AND KEY'S GRASS-MOWING MACHINE

(ALLEN'S AMERICAN PATENT).

Before introducing this Machine to the English public, BURGESS & KEY determined to fully test its capabilities, and the all-important point—durability. One Machine cut, on the farm of Mr. C. Hall, Havering, Romford, Essex, 83 acres Grass: and the same Machine afterwards cut, on the farm of Mr. Tabrum, Bovis Hall, near Brentwood, Essex, 100 acres Grass, and 20 acres Clover. The work done was declared to be better and lower than the scythe, and at the rate of 1 acre per hour. Orders have been received from both those Gentlemen, and numerous others, for Machines for next season. Price £30.

BURGESS & KEY'S Manufactory is entirely devoted to REAPING MACHINES and MOWING MACHINES.

95 NEWGATE STREET, LONDON.—MANUFACTORY, BRENTWOOD, ESSEX.

FURTHER PARTICULARS AND CATALOGUES SENT ON APPLICATION. (39)

By Her Majesty's Royal Letters Patent.

Sold by all Chandlers, Grocers, &c., &c. (7)

RANSOME'S PATENT IMPERISHABLE SILICIOUS STONE.—Chimneypieces, Balustrades, Capitals, Trusses, Terminals, Fountains, and Vases; also, Enamelled Stone Chimneypieces, of great beauty and novelty, at reduced prices. Monumental or Mural Memorials, Grave Stones, Space Markers, and Indicators for Cemeteries, &c., of every description, at the lowest price.

RANSOME'S PATENTED PROCESS FOR PRESERVING STONE.—Invaluable in its application to Public Edifices and Private Residences. By this process the softest and most friable stone can be rendered impervious and imperishable, and decay at once arrested and prevented.

RANSOME'S PATENT STONE FILTERS FILTERING SLABS.—Manufactured for every Private or Domestic purpose, for Manufactories, Public Companies, Shipping, &c. Several hundred thousand gallons of water are filtered daily by Ransome's Patent Stone Filtering Slabs, for the town of Southampton. They have also been adopted by the Admiralty, the Board of Ordnance, the Colonial Land and Emigration Commissioners, and other Public Bodies for several years; also in the City of Rotterdam, with the most perfect success.

For particulars, specimens, illustrations, and agencies, apply to

Mr. FREDERICK RANSOME,

WHITEHALL WHARF, CANNON ROW, WESTMINSTER;

OR PATENT STONE WORKS, IPSWICH.

A liberal discount allowed to the Trade or to Shippers. (14.

A NEW DISCOVERY IN WASHING HOUSEHOLD LINEN.

NO FAMILY SHOULD BE WITHOUT HANCOCK'S UNIVERSAL WASHING MACHINE. It effectually cleanses the Crevices of Baby-linen, Collars, Wristbands, &c., without the possibility of injuring the Linen or Collars. Received 500 Testimonials.

PRICES.

No. 2 Washes 9 Shirts in from 3 to 10 minutes; or 4 Sheets in 5 minutes	£5 5 0
No. 3 Washes 12 Shirts in from 3 to 10 minutes; or 6 Sheets in 5 minutes	7 11 0
No. 4 Washes 18 Shirts in from 3 to 10 minutes; or 12 Sheets in 5 minutes	12 12 0

And all other Articles in proportion.

J. L. HANCOCK, Sole Manufacturer and Patentee, 62 Pentonville-road, London. (37)

CHUBB'S LOCKS, FIREPROOF SAFES, CASH AND DEED BOXES.

Complete lists of sizes and prices may be had on application.

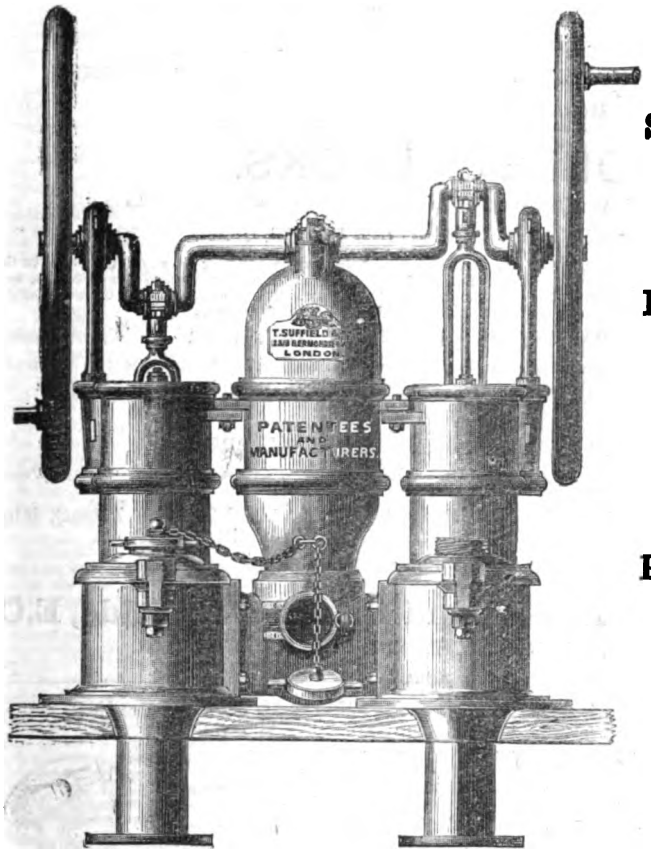
T. SUFFIELD AND CO.

Call the particular attention of

SHIP-OWNERS, SHIP-BUILDERS, AND COMMANDERS OF STEAM AND SAILING VESSELS,

to the Simple and Efficient Arrangements of their

PATENT PUMPS.



Ships' Pumps

AND

Fire Engines,

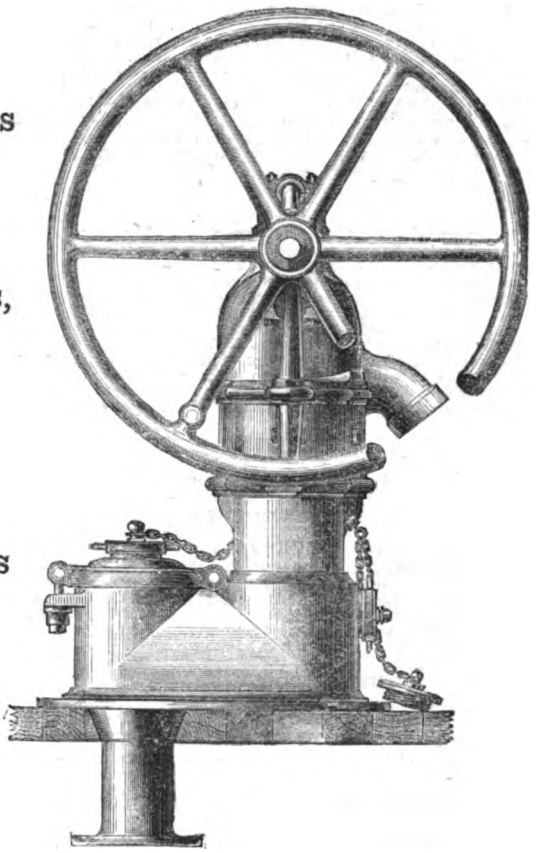
Fixed and Portable.

WITH

Patent Valves

AND OTHER

Improvements.



These Pumps are free from that liability to choke which is common to other Pumps, and their Working Parts are not susceptible of derangement either from wear or from being long out of use. They pass entirely through them, with ease, any substance that may enter the Suction Pipes. The Novelties in these Pumps are their adaptation to the varied duties of Ships' Pumps; the facilities they afford for Cleansing the Suction Pipes, and for Sounding or Examining the Valves; the readiness with which they may be used for Ventilating the Bilge, or for acting as a Syphon either for Watering the Ship, or for extinguishing Accidental Fires on board; the rapidity with which they can be converted into Fire Pumps, or be applied to the Washing of Decks; and their capability of Pumping from Several Compartments.

T. SUFFIELD AND CO.

Also respectfully solicit the attention of STEAM SHIP BUILDERS and OWNERS to their Large and Varied STOCK of

ASSORTED STORES FOR MARINE PURPOSES.

They keep a Large Stock of Goods, of their own Manufacture and from the Best Makers, constantly on view; so that by a visit to their Works or Depôt, much valuable time may be saved by Managers, Engineers, and other Gentlemen who may require such Stores, together with a further saving in the cost of such Articles.

DEPOT, 116 FENCHURCH STREET, E.,

THE CONSTRUCTION OF WROUGHT IRON BRIDGES; embracing the Practical Application of the Principles of Mechanics to Wrought Iron Girder Work. By JOHN HERBERT LATHAM, M.A., Civil Engineer, Fellow of Clare College, Cambridge.

Cambridge: MACMILLAN & Co., and 23 Henrietta-street, Covent-garden, London.

From the DERBY MERCURY.

"A very valuable and interesting work. . . . . The practical and scientific man will be able to judge of its importance when we say that the promises held out in the preface are fulfilled in the most painstaking, clear, and accurate manner. To the professional man we should imagine Mr. Latham will have rendered valuable service by this book, which is not without scraps of information interesting to the most uninitiated of readers. . . . . We have no hesitation in saying that it is a work of the greatest value, not only to professional men, as an aid to practice, but to the world at large, as tending to reduce the science to mathematical accuracy, and so lessen the chance of accident." (88)

HOBBS'S LOCKS.

The attention of Architects and Builders is respectfully invited to

HOBBS'S NEW MORTISE LOCKS,

Which are now manufactured by PATENT STEAM MACHINERY, and, while superior to any other locks in the market, are sold at a price which defies competition. The Plates are made of number "Twelve Gauge" Iron, and being so thick, the pins cannot be loosened by the constant jarring of the door. The security consists in four double-acting levers, while, to secure unusual freedom of motion and prevent the wear of the parts,

HOBBS'S PATENT FRICTIONLESS FOLLOWER

Is also applied. The retail price of these Locks is 10s., from which a liberal discount is allowed to the trade.

HOBBS'S NEW MORTISE LOCKING LATCHES FOR STREET DOORS,

Price 18s. And

HOBBS'S NIGHT LATCHES, RIM OR FLUSH, PRICE 10s.,

Are also recommended, together with every description of Lock required for house and cabinet work. Lists of Prices will be forwarded on application, post free.

N.B.—A complete Assortment of FIRE and BURGLAR-PROOF SAFES (Milner's Patent), fitted with HOBBS'S PATENT PROTECTOR LOCK, POWDER-PROOF.

ALSO, STRONG-ROOM DOORS, CASH AND DEED BOXES, ETC.

Address—Hobbs, Ashley, and Co., 76 Cheapside, E.C.

MANUFACTORY, ARLINGTON STREET, NEW NORTH ROAD.

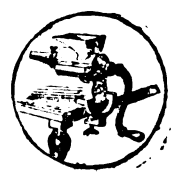
(86)

These Machines are admirably adapted for cutting up Food for Poultry.

A FIRST-CLASS SILVER MEDAL

Has been awarded to Messrs. NYE & Co., at the Paris Universal Exhibition, 1855, for their Improved Patent

SAUSAGE MAKING
AND GENERAL
MINCING MACHINE,



FOR PRIVATE FAMILIES, HOTEL KEEPERS, PASTRYCOOKS, PORK BUTCHERS, ETC.

THE Press throughout the country have spoken in the highest praise of this little Machine. From among them we select the opinions of the two principal Journals.

"Among other objects in the show worthy of special notice, we may mention the very ingenious Mincing Machine, exhibited by NYE & Co.; it is extremely clever, and, for the mechanical skill which it displays, is eclipsed by nothing in the whole show."—*Times*, July 14th, 1853.

"On Stand 12, we met with one of the gems of the yard, invented and manufactured by NYE & Co., of Wardour-street, Soho, London. This Machine is for making Sausages, &c., mincing up, mixing, and at the same time forcing the meat into the skins; it will mince 8lbs. of meat in four minutes; it will also cut suet, vegetables for soup, &c. It may likewise be used for various other purposes. It is made of metal, very strong, durable, and compact, and is particularly adapted for private families. Price £2 2s. This is a little thing every husband ought to carry home to his wife, who, we are satisfied, will turn it to the best account, and save the price."—*Mark Lane Express*, Aug. 15, 1854.

This Machine will mince, mix the seasoning, and force into the skins at the same time. It cuts all kinds of Cooked Meat, Forced Meats, Suet, &c. It will also cut Vegetables for Soups, Fruit for Mincemeat; and it will be found useful in Mixing and Mincing for many other purposes, and, being all metal, does not absorb the juices of the meat, and is easily cleaned with boiling water. Price £1 10s., £2 2s., and £3 3s.

Also a small

MINCER FOR THE DINNER TABLE, TO ASSIST DIGESTION,

Loss of Teeth, &c. Price 30s.

By Her Majesty's Royal Letters Patent.

S. Nye's Patent Improved Coffee Mill.

PRICE TEN SHILLINGS.

The large and rapidly increasing sale of these Mills, and the many Testimonials which have been received, is a guarantee that they only require to be known to secure their general adoption.

S. NYE, INVENTOR, PATENTEE, AND MANUFACTURER,
79 WARDOUR STREET, SOHO, LONDON, W.

The above Machines will be carefully booked to any address, on receipt of Post Office Order for the amount, payable to Samuel Nye, Post Office, Coventry-street, Soho.

Plans, &c., at Mr. E. Filliter's, C. E., Borough Surveyor, Town-hall, Leeds. Tenders to 10 a.m. 4th Feb.

GAS, *Devonport.*—The Commissrs. ask tenders for lighting Devonport with gas. Apply to Surv. of Devonport and Stoke-Damerel, Devon, to Jan. 27.

STEAM-ENGINE, PUMP, &c., *Bury St. Edmunds.*—The Paving Comms. ask tenders for a 3-H.P. high-pressure steam-engine for raising water; a deep Well-Pump for raising 4,000 galls. per hour; a circular iron-tank, 15 ft. diameter and 10 ft. deep; and about 3,500 yds. of water-pipe, diam. 8 in. by 2 in. inclusive. Tenders to Mr. Sparke, Clerk to Board, on or before Feb. 2. Mr Sparke will supply further particulars. No tender necessarily received.

SCAVENGING, *Oxford.*—Tenders received to Jan. 31, by Mr. Galpin, Surveyor to the Oxford Comms., Town Hall-yard, (where speci. may be seen), for sweeping, cleansing, and watering streets; also, for carting materials for repairs of roads, &c.

CHURCH, *Shropshire.*—To rebuild parish church of Bishop's Castle, Salop, for seating 700 on ground-floor. Mr. Nicholson, diocesan architect, Hereford, gives further informn., or plans be seen at the Six Bells, Bishop's Castle. Tenders sent to architect by 14th Feb.

CEMETERY CHAPEL AND LODGE, *Sudbury.*—Burial Board of St. Peter and St. Gregory, All Saints, and Ballingdoncum, Brundon, Sudbury (Suffolk and Essex), will enter into contract for two Cemetery Chapels and Lodge. Plans and specifications have been adopted by the Board, may be seen at the Town Hall, Sudbury, Durdon, to Mr. R. Ransom, Clerk, by noon, 1st February. The Board decides at 7 same evening.

HOUSES AND SCHOOLS, *England.*—Trustees of Sutton St. James's Charities, Lincolnshire, will erect two School-rooms and a master's house, at Sutton St. James's. Plans and specs. seen at Mr. J. P. Sturton's, Solicitor, Holbeach; to whom tenders must be sent on or before 29th inst.——Tenders for erection of a residence at Hartford, Cheshire, near the Railway Station, for F. H. Firth, Esq. Plans and Specs. at his present residence, Hartfort House, to-morrow, Sat., must be sent in to Mr. Firth, by Mon. Jan. 24. No tender necessarily accepted. Mr. J. Douglas, jun., of Sandiway, is architect.

HOUSES AND SCHOOLS, *Scotland.*—A house on the lands of Pitfodels, plans at Messrs. A. & W. Reid, and Mackenzie's, architects, until 27 inst. Tenders to following day.—Dwelling house and steading of office on the farm of Rogiehill, Skene. Plans with Overseer, at Kirkville. Tenders to Jan 29.——Converting the buildings of the Old Flesh Market, at Old Meldrum, into houses for the poor. Plans &c. from Mr. W. Don, Inspector of Poor, Old Meldrum. Tenders to Jan. 29.—For additions and repairs to the School and Schoolmaster's house at Cartly. Specs. on application to Mr. M'Pherson, Gibsson. Tenders to Jan. 27; the premises shown by schoolmaster.——School and schoolhouse, in the village of Old Deer. Plans &c. with Mr. Clarke, architect, Strichen. Tenders to Jan. 24th.

BOUNDARY WALL, *Birmingham.*—The guardians of the Birmingham Poor will receive tenders for erection of a Boundary Wall at the Workhouse. Specs. &c. seen on application at Parish Offices, Paradise-st., where printed forms of tender may be had. Sealed tenders at Parish Offices, 1st Feb. Each proposal must contain names of two persons to become sureties for performance to a moiety of tender. No tender necessarily accepted. Works to commence 1st March, and completed in three months.

ROAD MATERIALS, *Staffordshire.*—Willenhall Local Board of Health will receive Tenders for 600 Tons of Pebbles, during the present year, 50 tons per month, in any part of the parish. Tenders stating price per cub. yard, by Sat. 29th inst. to Clerk, Board of Health, Willenhall.

Winchester.—The Commissioners of Winchester Pavement ask for Tenders (to be sent to their Surveyor, Mr. H. Newman, Jewry-st., that city), up to Jan. 28th, for supplying 400 cubic yards of flints (broken or unbroken) for carriage roads. To be paid for within a month.

IRON WORKS, *Wanted.*—A Small Forge and Rolling Mill required in Lancashire, Cheshire, or neighbourhood, with about 6 Puddling Furnaces, or convenience for them, and plant for turning out about 50 tons of bar iron per week. Address to J. H., *Engineer* Office, 163 Strand, London.

RAILWAY STORES, *Ireland.*—The Directors of the Waterford and Limerick Railway will receive Tenders during the half-year commencing Feb. 1, for English bar and plate iron, for fire bars, nails, steel files, tools, boiler tubes for engines, wheel tyers, chains (joints and middle), sleepers, keys, trenails, and screws; timber (American oak and elm, red pine, deals, &c.), turf, carriage trimmings, glass, door-handles, &c., canvas and leather, brushes and brooms; oils, best Colza, refined rape, boiled, palm, &c.; paints, turpentine and varnishes, tallow, wick and cotton waste, and waggon sheets. Particulars, &c., on application to the Solicitor, Mr. T. Ainsworth, The Mall, Waterford. Parties applying are to state the articles for which they propose tendering. Offers addressed to the Directors till the 25th inst.

EMBANKMENT, *Ireland.*—Quantities for the Shannon Grove Embankment Company, Limerick, can be had from Mr. H. Townlow, C.E., 67 Amiens-street, Dublin.

CHURCHES, *Ireland.*—The Ecclesiastical Commissioners for Ireland, on or before the 5th Feb., will receive proposals for rebuilding the Church of St. James, Dublin; for fitting up interior of the Church of Rathcunnell, co. Westmeath; and for repairing and painting externally the churches of Dunmore, Moylough, co. Galway; Fenagh, co. Leitrim; Kicoleman, co. Mayo; Strut, co. Westmeath. Specs. in the hands of resident ministers of the parishes. No tender necessarily accepted. Sealed tenders to be addressed, "The Ecclesiastical Commissioners for Ireland."

CHAPEL SCHOOLS, *Dublin.*—The quantities for Newbridge Chapel School can be obtained from Mr. F. Regan, 55 Bolton-street, Dublin.

HOUSES, *Dublin.*—Tenders will be received for making alterations in houses 5 & 6 Lower Bridge-street. Plans, &c. with Mr. J. S. Butler, architect, 16 Hume-street, Dublin. Proposals on or before 27th inst. No tender necessarily accepted.

TIMBER FENCING, *Scotland.*—The Directors of the Caledonian Railway will receive tenders for about 20,000 rails of Larch Fencing. Particulars from Mr. G. Graham, Engineers Office, Buchanan-street Station, Glasgow, till 2 th inst, on which day offers must be lodged with Secretary, 85 Renfield-street. No tender necessarily accepted.

WIRE FENCING, *Scotland.*—Tenders are wanted to erect about 2,400 lineal yards of wire fencing, on the line of march between the lands of Kidlan, on Newton Estate, and Strobshiel, six miles north of Haddington. Specs. in hands of Mr. Dalgleish, W.S., 14 Rutland-square, Edinburgh. Tenders lodged by Feb. 9th.

DRYSTONE DYKES, *Scotland.*—Tenders are wanted for the erection of several thousand yards of Drystone Dykes on the farms of Airdrie Mains, Frithfield and Drumrack, on the Estate of Airdrie, Crail. Specs. in hands of respective tenants, who will cart materials. Tenders sent to Mr. Dalgleish, 14 Rutland-square, Edinburgh, by the 9th Feb.

HAVELOCK MONUMENT, *Sunderland.*—The Committee will receive designs and estimates for the erection of a bronze Colossal Statue, in the Mowbray-park, figure not to exceed 9ft., and pedestal 10 to 12 feet; models, 2 to 3 feet, to be forwarded to the Mayor of Sunderland, by 1st March. The monument on a prominent eminence, having a front of rock about 40 feet in height.

OLD RAILS, *London.*—The Directors of the South-Eastern Railway Company will receive tenders for a quantity of old rails, at Angerssein Wharf, Thames. Terms, &c. on application to Storekeeper. Tenders addressed to Mr. S. Smiles, Sec., London-bridge Terminus, by 26th inst.

RAILWAY ACCOUNTANT, *India.*—The Bombay, Baroda, and Central India Railway Company will engage an experienced accountant for India. Preference given to one who has held a similar appointment in a railway undertaking in working operations. Candidates to address to the Sec., Mr. C. H. Kennedy, 10 Liverpool-street, New Broad-street, London, E.C. (with testimonials), by Feb. 1. Salary £600 per an. Successful canditate to proceed to India forthwith.

Now ready, price 2s. 6d.,

THE LITERARY AND

EDUCATIONAL YEAR BOOK

FOR 1859.

THE LITERARY AND EDUCATIONAL YEAR B contains a Catalogue of the Books published in 1858, the name of the author, price, size, binding, and publi of each book. Also the names and addresses of the London Publishers.

THE LITERARY AND EDUCATIONAL YEAR BOOK contains a list of the principal American and Foreign Books published in 1858, with the name of the author, price, size, binding, and publisher of each book.

THE LITERARY AND EDUCATIONAL YEAR BOOK contains a list of the works printed by order of the Commissioners of Patents for Inventions, including chronological indices and classified abridgements of all specifications of patented inventions and the Free Libraries and Institutions where new works, including 1,000 volumes, may be consulted.

THE LITERARY AND EDUCATIONAL YEAR BOOK contains lists of the new Maps and Prints published during 1858, with the size, price, and publisher of each.

THE LITERARY AND EDUCATIONAL YEAR BOOK contains lists of all the Metropolitan and Provincial News papers, stating where each paper is published, when it wa established, its peculiar politics or principles, day of publication, and price.

THE LITERARY AND EDUCATIONAL YEAR BOOK contains the names and addresses of all the principal Newspapers in all the great towns and cities of the Continent; also those published in the British Colonies and the United States of America.

THE LITERARY AND EDUCATIONAL YEAR BOOK contains lists of all the Weekly, Monthly, and Quarterly Publications of the Metropolis and the Provinces, stating when and where each is published, and price.

THE LITERARY AND EDUCATIONAL YEAR BOOK contains the Learned, Philosophic, and Artistic Societies of the Metropolis, stating the nature and object of each Society, with the names of the Officers of each, the papers read before each in 1858, and all the necessary information about conditions of membership, entrance fees and annual subscriptions, days of meetings, &c.

THE LITERARY AND EDUCATIONAL YEAR BOOK contains the Public Metropolitan Libraries and Museums, and Lists of the Metropolitan and Provincial Schools of Art and Science, with the names of the principal promoters and teachers of each school.

THE LITERARY AND EDUCATIONAL YEAR BOOK contains a List of the Mechanics' and Literary Institutions Working Men's Colleges, and Mutual Improvement Societies; also a List of the Young Men's Christian Associations of the country.

THE LITERARY AND EDUCATIONAL YEAR BOOK contains Lists of Public Libraries, Penny News Rooms, and Clubs in the Metropolis; and Book Hawking Societies, Itinerary Libraries, and County Associations in the Provinces.

THE LITERARY AND EDUCATIONAL YEAR BOOK contains the names of the Universities of the country, with the Professors, Masters, Tutors, Examiners, Moderators, Officers, &c.; and the Principal Grammar Schools and Dissenting Colleges, with the Names of Head Masters, Tutors, &c.

THE LITERARY AND EDUCATIONAL YEAR BOOK contains the names of all who graduated at the London University during 1858, arranged in alphebatical order under their respective divisions.

THE LITERARY AND EDUCATIONAL YEAR BOOK contains the names of all the Successful Candidates of the Middle-Class Examination for 1858, with the Name, Address, Age, Place of Examination, and Local School of each Candidate. Also all the requisite information, including Regulations and Particulars, for the final Examination in June, 1859.

THE LITERARY AND EDUCATIONAL YEAR BOOK contains all the Prizes and First-Class Certificates awarded at the Final Examination of the Society of Arts Union of Institutes for 1858. Also the Subjects for Final Examinations in 1859, including Regulations for Candidates, with the names of Books of Reference recommended by the Council. Also the Names of the Examiners for 1859, and the Prizes offered.

THE LITERARY AND EDUCATIONAL YEAR BOOK contains the Names of Paid and Gratuitous Lecturers of the country, with their addresses, and General Subjects by each person.

THE LITERARY AND EDUCATIONAL YEAR BOOK contains a variety of other information on the Copyright and International Copyright Laws, Statistics of Public Libraries, Hints on the best mode of Establishing and sustaining Educational Institutions for the People, Female Education, Hints on Printing, Publishing, Advertising, &c.

THE LITERARY AND EDUCATIONAL YEAR BOOK contains upwards of 25,000 facts appertaining to Literature, Art, Science, and Education.

NEW PERIODICAL.

On the first of March next will be published, price 6d., No. 1 of the LITERARY RECORD, a new monthly periodical, to be conducted on a new principle, and which will differ from every existing periodical as much as chalk from cheese! The LITERARY RECORD will, to all intents and purposes, supply a want, and will be found a *vade mecum* for Authors, Editors, Journalists, Artists, and the whole Book-making, Book-selling, and Book-reading public. If the proprietor's idea be realised—and there is no reason why it should not—then the LITERARY RECORD will become the constant companion of every public Reading-room, Editor's-desk, and Bookseller's-counter in the country.

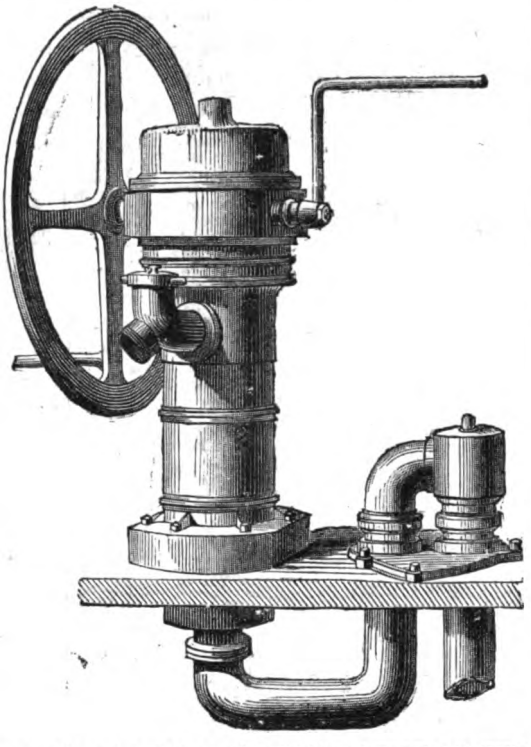
Under the Patronage of the Board of Admiralty.

SHIPS' PUMPS OF HER MAJESTY'S NAVY.

JOSIAH STONE,

Sole Manufacturer of DOWNTON'S well-known and much approved SHIPS' PUMPS, which have been used in preference to all others on board the vessels of Her Majesty's Navy, for upwards of thirty years, and have given the greatest satisfaction, effectually answering all the purposes required of any Ships' Pumps, and capable of throwing most powerful jets of water in case of fire.

These Pumps have also been most extensively used on board merchant vessels, both at home and abroad, and have been supplied to the Royal Navies of France, Prussia, Holland, Russia, Spain, and Turkey. The Pumps are portable, as they may be easily removed from the ship and put to work in a boat alongside in a few minutes. Each pump is fitted with a large foot valve plate (which may be placed in any part of the vessel most convenient), and from which communication is made to any number of distinct compartments in the vessel. In case of any of these pipes fouling, the water, by an almost momentary attachment, may be forced from the Pump downwards, so as to clear all obstructions, preventing any possibility of stoppage. The valves are of the simplest description, and being faced with ordinary leather discs, the latter may be renewed in a few minutes by the most inexperienced hands. By the peculiar construction of these Pumps, a most perfect and uninterrupted flow of water may be maintained; so uniform as to be undistinguishable from that proceeding from a cistern. The Pumps are made of several sizes, those of 7, 9, and 12 inches bore being most generally used. They may, however, be ordered of any dimensions required, and may be fitted either with one or two fly wheels. A standard, &c., is also supplied with these Pumps, to enable them, when necessary, to be used as ordinary hand-lever pumps.



JOSIAH STONE, Engineer, Manufacturer of all descriptions of PUMPS and FIRE ENGINES for Land and Ships' Use; Brass and Iron Founder and Finisher, Nail and Rivet Maker, &c.

CONTRACTORS FOR FIRE-ENGINES, ETC., TO THE WAR DEPARTMENT,

RAILWAY STATION, DEPTFORD, AND 12 GARLICK HILL, CITY, E.C.

(82)

ARTESIAN WELLS, BORING TOOLS, PUMPS, &c. Engineers, Architects, Surveyors, Builders or others requiring a good supply of Water may have any quantity procured by W. SPELLER, 14 York-street, Blackfriars'-road, London, where may be had any quantity of Tools for Sinking or Boring, from 2 to 20 inches diameter, and from 100 to 2,000 feet depth; also Men and Tools to bore for Railroads, Minerals, &c., in any part of the world. Boring Tools and suitable Pipes for exportation, with full instructions for their use.

Builders, Contractors, Brickmakers, Barge and Ship Builders, and others, can be supplied with Wrought or Cast Iron Pumps, Double or Single, for excavation of Deep Wells, from 3 to 14 inches in the bore, and from 6 to 130 feet in length, to work by Hand or Steam Power.

Hot-water Apparatus for Conservatories, &c., on the most economical and improved principles.

Also Manufactory for Captain John Grant's much improved Cooking Apparatus. (44)

TO BRASS-FOUNDERS, ENGINEERS, &c.

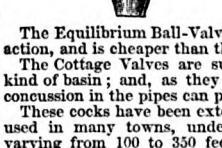
THE PATENT PLUMBAGO CRUCIBLE COMPANY having completed the enlargement of their premises, beg to call the attention of all users and shippers of Melting Pots to the great superiority of the PATENT CRUCIBLES, which have been used during the last three years by some of the largest melters in England and abroad. In addition to their capabilities of melting an average of from thirty-five to forty pourings; they are unaffected by change of temperature, never crack, but can be used till worn out, requiring only one annealing for several days' work, and become heated much more rapidly than ordinary pots, effecting thereby a saving of more than fifty per cent. in time, labour, fuel, and waste. The Patent Plumbago Crucible Company also manufacture and import clay crucibles, muffles, portable furnaces, sublimate pans and covers, glass-pots, all descriptions of fire-standing goods, and every requisite for the assayer and dentists. For Lists, Testimonials, &c., apply to Battersea Works, London, &c. (43

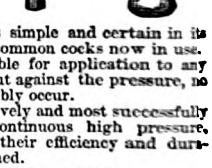
PUMPS
FOWLER & Co.
WHITEFRIARS STREET,
FLEET STREET,
— LONDON. —

HYDRAULIC MACHINERY OF EVERY DESCRIPTION, FOR HOME USE OR EXPORT, UPON THE LARGEST, OR SMALLEST SCALE, MANUFACTURED, FIXED, OR LENT ON HIRE: AN EXTENSIVE STOCK KEPT READY FOR GENERAL PURPOSES.

HIGH-PRESSURE VALVE-COCKS, LAMBERT'S PATENT.

Equilibrium Ball Valve. Cottage Closet Valve.





The Equilibrium Ball-Valve is simple and certain in its action, and is cheaper than the common cocks now in use.

The Cottage Valves are suitable for application to any kind of basin; and, as they shut against the pressure, no concussion in the pipes can possibly occur.

These cocks have been extensively and most successfully used in many towns, under continuous high pressure, varying from 100 to 350 feet; their efficiency and durability is, by experience, established.

THOMAS LAMBERT and SON,
Brass Founders, Short-street, New-cut, Lambeth.

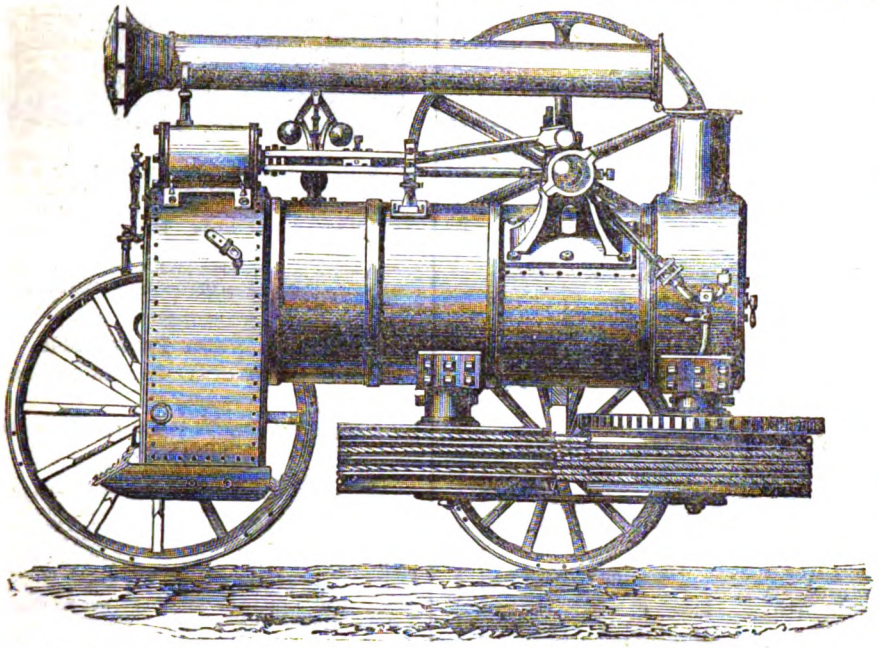
COLLINSON HALL'S PATENT WINDLASS
AND
STEAM PLOUGH AND IMPLEMENT GEAR.



The object of this mechanism is to render effective the WHOLE POWER of engines used in drawing ploughs or other implements in tilling land. This is accomplished by carrying the wire rope, in the form of the figure 8 round horizontal drums fixed (so as to be easily removable) under the engines. By this arrangement the evils arising from overlaying the coils of rope when wound upon the capstan principle are avoided, as also are those arising from an unequal wear of the ordinary horizontal pulleys. In the new arrangement the solid drum is constructed with several grooves, while the other is composed of as many independent pulleys as there are grooves in the drum. The upper or lower pulley, as the case may be, revolves in one direction, while the remaining ones revolve in the opposite direction. The solid drum only is driven directly by the engine, while the pulleys revolve by frictional contact, and thus all slipping is avoided.

The simplicity of this Gear is one of its chief recommendations, little or no framing being required. The axes being bolted to the bottom of the boiler, a simple rod or beam retains them in a vertical position. The Gear may be fitted and again unshipped from an engine (by means of keys through the axes, by which the Gear is retained in place) in less than ten minutes.

APPLICATIONS FOR LICENCES TO BE MADE TO

COLLINSON HALL, PRINCES GATE, ROMFORD, ESSEX.

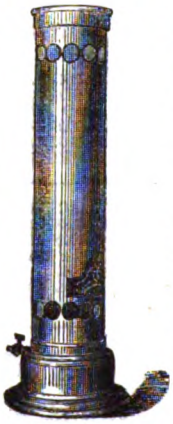
VENTILATION WITHOUT FLUE.

KUKLA'S PATENT STOVES, at 18s., £1 5s., and £2 10s.



KUKLA'S newly-invented Deflagrator—the first and only perfect GAS STOVE. Guaranteed to burn without flue — without dust, smell, or smoke, producing a great and pure heat with the least expenditure of Gas.—*Vide Society of Arts' Journal.*

Patronised by the English and French Government.

Scientific in Principle,
Simple in Construction,
Healthy and efficient in use.

The Deflagrator Stove is cheap, portable, and suited for every situation; and from the principle on which it is constructed, viz., expanding to a sixfold volume the gas used, is capable of warming any given space both more quickly and more thoroughly than any other means; while its addition forms a sure remedy for any ill-warmed or ill-ventilated apartments.

The £1 5s. Deflagrator warms a room of 2,000 cubic feet at a cost of 3d. per day.

The £2 10s. Deflagrator warms 5 to 6,000 cubic feet at a cost of 6d. per day (twelve hours). The Greenhouse Stove at 18s.

Patentee and sole Manufacturer, F. X. KUKLA, 194 Pentonville-road, London.

Country orders promptly attended to. Carriage free to any Railway in London. Post-office Orders should be made payable to FRANCIS XAVIER KUKLA, General Office.

N.B.—Every Stove separately tested before sent out.

The NEW GAS COOKING STOVE for 10 persons, price £3.

CLAYTON, SHUTTLEWORTH, AND CO.,

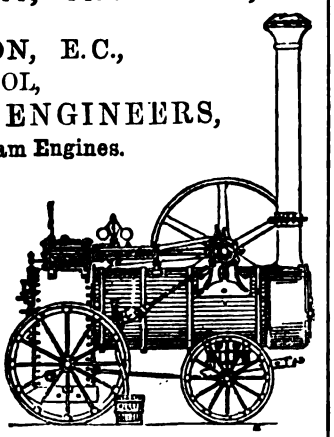
OF LINCOLN,

78 LOMBARD STREET, LONDON, E.C.,

AND 36 DALE STREET, LIVERPOOL,

AGRICULTURAL AND GENERAL ENGINEERS,

And Manufacturers of Portable and Fixed Steam Engines.



Combined Threshing Machines, which dress the corn ready for market at one operation. Grinding Mills, Saw Benches, Pumps for Irrigation and Mining purposes, with all necessary gearing for being driven by steam power. Full particulars and estimates given on application to the above address.

C. S. and Co.'s PORTABLE STEAM ENGINES are adapted for every purpose to which steam-power can be applied. When intended for winding, they are fitted with reversible link motion and winding gear. They are easy of removal, as may be seen by the engraving, and can be set to work immediately on arrival.

C. S. and Co. are now doing an extensive foreign and colonial business, and are prepared to send off engines and machinery of the before-mentioned kinds in a few days from the date of order. They would also call attention to the important *reduction in prices* made for the new year.

For Exportation.---The above can be obtained through British Merchants, Shippers, and Colonial Agents. (23)

IMPROVED MACHINERY FOR AGRICULTURISTS.

RICHARD GARRETT & SONS,

LEISTON WORKS, SAXMUNDHAM, SUFFOLK,

(ESTABLISHED A.D. 1778),

EARNESTLY solicit the continued support of their numerous Friends, Agriculturists, Shippers, and others; the additions made to their Works during the present year, in the erection of new sets of Workshops, fitted with the best mechanical appliances for producing Machinery of the most improved construction, expeditiously and economically, justifies their soliciting increased support, while their leading reputation as Inventors and Manufacturers of FIRST CLASS Agricultural Machinery, is a sufficient guarantee that every Machine supplied from Leiston Works will prove to the entire satisfaction of the purchaser.

R. G. & S. are now manufacturing the following Machines and Implements, which they guarantee to be thoroughly efficient in every respect:—

PORTABLE AND FIXED STEAM ENGINES. } From 4 to 40 Horse Power, suited for every kind of work
SELF-PROPELLING AND TRACTION ENGINES. } to which Steam Power is applied.
STONE GRINDING MILLS.
MORTAR AND PUG MILLS.
MILLWRIGHTS' WORK of all kinds.
SAWING MACHINERY, from 4 fo 20 Horse Power.
BRICK AND TILE MACHINES.

IMPROVED SETS OF FARM MACHINERY, for Large Occupations.
PORTABLE AND FIXED MACHINERY, for Thrashing and Dressing Corn.
THE PRIZE BOLTING AND OPEN-DRUM HORSE-POWER THRASHING MACHINES.
CORN DRESSING MACHINES, for Hand, Horse, Water, and Steam Power.
BARLEY AVELLING MACHINES.
CHAFF CUTTERS, for Hand, Horse, Water, and Steam Power.
PATENT TURNIP CUTTING AND PULPING MACHINES.

THE PRIZE CORN AND SEED DRILLS.
PRIZE CORN AND SEED DRILLS WITH MANURE APPARATUS.
PRIZE SEED AND MANURE DRILLS.
LIQUID, SEED, AND MANURE DROP DRILLS.
CHAMBER'S PATENT BROADCAST MANURE DISTRIBUTOR.
GARRETT'S PATENT HORSE HOE for all Crops.
PATENT REVOLVING HOES for Root Crops.
IMPROVED PLOUGHS AND REAPING MACHINES.
&c. &c. &c.

which full detailed particulars will be found in R. G. & SONS' ILLUSTRATED CATALOGUE, sent postage free to any address, in English, French, or German; and any of the above Machines will be shown in operation at R. G. & Sons' Farm, near the Works, on their receiving a few days' notice.

A Copy of R. G. & SONS' new COLONIAL LIST will be forwarded free to any of the Colonies, and Shippers will be supplied with these lists, with their names and addresses printed on, free of charge, by making application for the same.

ADDRESS—R. GARRETT & SONS, LEISTON WORKS, SAXMUNDHAM, SUFFOLK. (57)

WATER POISONED BY LEADEN PIPES.

"The above engraving represents accurately a section of a leaden pipe, which was employed for a short time in conveying water from a well on the grounds of Mr. Dick, of Bonchurch, Isle of Wight. The water has cut these deep pits almost through the pipe, and not only upon the portion which we have illustrated, but has formed similar chasms throughout the centire length."—*Expositor.*

Poisoned Water Preventable.

BY THE USE OF GUTTA PERCHA TUBING.

The Gutta Percha Company have been favoured with the following letter,

From Dr. MURRAY, Hull.

"It is impossible to conceive of anything more injurious, or destructive to the health of the community than the use of *leaden pipes* for the conveyance of water. The poisonous salts of lead thereby communicated are most insidious and subtle. I hail with gratitude the substitution of Gutta Percha Tubing. I have had the leaden pipe of my own house removed, and its place supplied with one of Gutta Percha. Nothing can be better. I have also recommended it to others, who have adopted the expedient.

Resistance for Frost.

The Gutta Percha Company have been favoured with the following Letters in reference to the non-conducting properties of Gutta Percha Tubing, in the resistance of Frost.

From J. ARMSTRONG, Esq., M.D., Gravesend.

"My private house, which was supplied with your Gutta Percha Tubing some five or six years ago, has never required the slightest attention; and previously, there was no winter passed that we were not deluged in consequence of the bursting of the leaden pipes."

From HENRY BROWN and SONS, Western Works, 108 Rockingham-street, Sheffield.

"We have now a positive proof of the frost-resisting properties of the Gutta Percha Piping. On our premises we have a leaden Pipe and a Gutta Percha one lying side by side. The leaden one has been completely frozen up at least ten days, and the Gutta Percha one is still unaffected.

Every Variety for Gutta Percha Articles.

AND

Journal of Engineering, Agricultural Machinery, Manufactures, and Shipbuilding.

(Registered for transmission abroad.)

[EDITED BY R. A. BROOMAN AND E. J. REED.]

VOL. 1.—NO. 5. [NEW SERIES.]

LONDON: FRIDAY EVENING, JANUARY 28, 1859.

PRICE FOURPENCE. BY POST 5d.

PRINCIPAL CONTENTS.

	PAGE.
LEADERS:—	
Specifications of Patents for Inventions	69
The Silver Coinage	69
Laying-off; or, the Geometry of Shipbuilding	70
Shipping Statistics	71
Literature	72
Captain Raymond's Life Rafts	73
Johnson and Varley's Improved Pressure and Vacuum Gauges	74
The Conservation of Force	75
Whiteley's Apparatus for Making Millboard and for Cutting Millboard and Paper	76
Wood's Patent Stable Fittings	76
Normandy's Patent Marine Freshwater Apparatus	77
Manchester Literary and Philosophical Society	78
Baggs' Improved Electrical Apparatus	78
The National Life-Boat Institution	79
List of New Books	79
Indian Items	79
Exploration of Australia by Balloons	79
Metal and Coal Trades, &c.	79
Notes from the South West	80
Notes from the Eastern Districts	80
Current Events in the Centres of the Iron, Coal, Machine, and Shipping Trades	81
Provisional Protections	81
Notices of Intention to proceed with Patents	82
Patents on which the Third Year's Stamp Duty has been Paid	82
List of Sealed Patents	82
List of Specifications, &c.	82
List of Designs for Articles of Utility Registered	82
Abridged Specifications of Patents	82
Prices Current of Metals	84
List of Miscellaneous Tenders Invited, and Engagements open	84

ENGINEERS' MACHINE TOOLS ready for delivery, and in progress: for Planing, Slotting, Shaping, Boring, Drilling, Screwcutting, Parallel and Cross-surface Turning; Wheel Cutting, Bolt and Nut Screwing; Nut Shaping, Washer Making, Rivet and Railway Spike Making, Boiler-plate Bending, Punching and Shearing.

MACHINE TOOLS for other purposes made to order.

JOHN TODD & Co.,
Kent Iron Works, Bridge-street, Greenwich (92)

STEAM ENGINES FOR SALE.

PORTABLE STEAM ENGINES, from 6 to 12 horse power,
STATIONARY STEAM ENGINES, from 4 to 50 horse power,
TUBULAR BOILERS, from 4 to 50 horse power,
CORNISH BOILERS, from 4 to 50 horse power,

Are in hand, and can be despatched on eight days' notice. Prices moderate. Workmanship and Material of the best description.

Apply to R. THORNTON & Co., St. Leonard's Iron Works, Edinburgh. (60)

GLADSTONE & Co., CONTRACTORS and ENGINEERS.

2 John-Street, Minories, London, E.C.,

Are prepared to ESTIMATE FOR and CONSTRUCT BRIDGES, PIERS, JETTIES, &c., in Iron, Wood, or Stone. Also to supply Cranes, Girders, Turntables, and Railway Work and Plant generally. (56)

ENGINEERING AND MECHANICAL DRAWING CLASSES.—Instruction given in Engineering and Mechanical Drawing, comprising the preparation of plans, elevations, and sections of marine and locomotive engines, with the detail and working drawings; also the method of delineating screws, bevel wheels, &c.; orthographical projection, and tinting, shading, and colouring taught.—For prospectuses of the Day and Evening Classes apply to Mr. T. J. HILL, at the offices, 15, Old-street, City-road. (73)

EDWIN JEWITT, ENGRAVER ON WOOD AND DRAFTSMAN, 1 Pickett-place, Strand, near Temple-bar. Engineering, Scientific, and Mechanical Designs accurately engraved. Manufacturers and Tradesmen's Catalogues illustrated. W.C. (84)

HART & SON, MALLEABLE IRON FOUNDERS, 4 Vine-street, York-road, Lambeth. Orders for Malleable Iron Castings executed within a week. (77)

CHUBB'S LOCKS, FIREPROOF SAFES, CASH AND DEED BOXES.

Complete lists of sizes and prices may be had on application.

CHUBB AND SON,
57 ST. PAUL'S CHURCHYARD, LONDON;
28 Lord-street, Liverpool; 16 Market-place, Manchester and Wolverhampton. (4)

TO WIRE ROPE MAKERS.—ARCHIBALD SMITH is now prepared to GRANT LICENCES for the use of his PATENT ROPE MACHINERY, guaranteed to work at six times the speed of any other, and to save upwards of fifty per cent. in the cost of making. It is used by the most eminent makers, and was also in the manufacture of the Atlantic Cable.—Apply to 69 Princes-street, Leicester-square, W. (8)

TO MARINE ENGINEERS, OR SHIP-BUILDERS.

THE PROPRIETOR of a VALUABLE PATENT for Double-expansive Marine Engines (by which great economy of space and fuel is obtained) is desirous of entering into arrangements with a respectable firm for the construction of the same. An adequate portion of the patent-right would be assigned by the advertiser to any firm taking the matter up; and he would render all assistance in his power, either in London or elsewhere, amongst ship-owners (to many of whom he is well known), in obtaining contracts, &c. Unexceptionable references given. Address C. E., MECHANICS' MAGAZINE Office, 166, Fleet-street. (76)

NOTICE OF DIVIDEND.

BANK OF DEPOSIT, No. 3 PALL-MALL EAST, LONDON, S.W.—The Warrants for the Half-yearly Interest, at the rate of 5 per Cent. per Annum, on Deposit Accounts, to the 31st December, are ready for delivery, and payable daily between the hours of ten and four.

PETER MORRISON, Managing Director.

10th January, 1859.

Prospectuses and Forms sent free on application. (91)

HALKETT'S GUIDEWAY STEAM AGRICULTURE will be Exhibited at Canning-place, Kensington Toll Gate, South of Kensington Gardens, on Wednesdays, the 9th, 16th, and 23rd of February, and to private view upon previous appointment. By this system, every operation of the Farm is performed by Steam Power, the land largely increased in value, and the cost of cultivation greatly reduced. A paper read before the Society of Arts, illustrations, &c., will be forwarded upon application to the Office, 80 Chancery-lane, W.C. (104)

TO ENGINEERS, ARCHITECTS, PATENT AGENTS, &c.

PHOTOGRAPHS OF THE HIGHEST CLASS and of any size, taken and reproduced at a most moderate rate of charge. Reproductions of faultless accuracy, of Machinery, Models, Drawings, &c. Orders attended to in town and country. Estimates forwarded.

SPENCER, READ, & Co., 4 Agar-street, Strand. W.C. (90)

FURNACE DOORS AND BARS.—Steam increased, fuel saved, and smoke prevented, by the PATENT REGULATING AIR-DOORS. Great economy from using the "Doubly-durable" fire bars.

J. LEE STEVENS, 1 Fish-street-hill, E.C. (87)

FIRE BRICKS.—THE FARNHAM INDESTRUCTIBLE SILICIOUS FIRE BRICKS have been greatly REDUCED in PRICE, and will be delivered at the Nine Elms Station, London, at 90s. per 1,000.—Address, G. H. OGSTON, J. M., Paine's Silica Works, Farnham, Surrey. (35)

VITRIFIED BLUE BRICKS are delivered at the Nine Elms Station, London, at 80s. per 1,000.—Address, G. H. OGSTON, J. M. Paine's Silica Works, Farnham, Surrey. (36)

ENGINEERS' TOOLS.

FOR SALE, a Self-acting Slide LATHE, 11-inch Centres, and Bed 12 feet long, complete; and TWO PORTABLE PUNCHING and CUTTING MACHINES, one suitable for ½-inch plates, and the other for ¾-inch plates, both adapted for steam or hand power.

Apply to Messrs. PAGE & CAMERON, Auctioneers and Valuers, 64 Old Broad Street, E.C. (117)

STEAM ENGINES.

FOR SALE, a New High-pressure HORIZONTAL ENGINE, of 14-horse power, 14-inch Cylinder, and 2-feet Stroke; and one of 30-horse power, 20-inch Cylinder, and 3-feet Stroke.

Apply to Messrs. PAGE & CAMERON, Auctioneers and Valuers, 64 Old Broad Street, E.C. (116)

TO ENGINEERS, INVENTORS, AND OTHERS.

WANTED, occasional employment by an expeditious Mechanical Draughtman, who has had considerable experience in assisting inventors in carrying out their plans, and afterwards introducing them to the notice of those willing to take them up. Or the Advertiser would not object to take the charge of a small machine shop or railway work.—Apply to J. J., 171 Strand. (99)

TO ENGINEERS' TOOL MAKERS, AND OTHERS.

THE ADVERTISER is desirous of meeting with an engagement as TOWN or DISTRICT AGENT for an Engineers' Tool Maker, or firm whose business lies amongst Engineers and practical men. He is an Engineer by profession, has for many years been engaged in bringing into operation several inventions, and can give unexceptionable references. A very moderate fixed salary only expected. Address M. C., MECHANICS' MAGAZINE Office, 166 Fleet-street. (78)

SCHOOL FOR MECHANICAL ENGINEERING and SCIENTIFIC EDUCATION, at the College, Chester.

In Addition to English and Mathematics, all the Pupils are taught Drawing suitable for the Architect or Engineer, and in the Laboratory the Principles as well as the Practice of Chemistry.

The use of Tools, the Construction of Machinery, and the Principles of Mechanism may be studied in the various Workshops of the School.

French and German are taught to all who desire it without any extra charge.

Chemical Analyses undertaken, Steam Engines and Machinery examined and reported upon, and Mechanism designed for special purposes. For further particulars apply to the Rev. ARTHUR RIGG, Chester. (95)

WATER GAUGES—WATER GAUGES.—Sir,—We find your German Gauge Tube superior to any other, and strongly recommend it. We were compelled to abandon the use of our water gauge until applying your glass tube.

WILCOX and Co., Millwall Pottery Company.

These Tubes are superior to all others; being a clear white, no mistake can arise in working. Guaranteed to stand a pressure of 500 lb.

Extensively used on all the principal lines.

To be had only of E. MOORE, 55 Upper Marylebone-street, W.; and 72 Great Titchfield-street, W.

*** Price List of Gauge Fittings, &c., on application. (98)

PUMPING MACHINERY.

GWYNNE AND Co., Engineers, London, manufacture and supply the following Machinery, of the most approved construction and with all the latest improvements:—Portable and Fixed Steam-Engines and Boilers of every description; Waterwheels, Windmills, Horse and Hand-power Machines; Pumping Machinery for the Supply of Towns, Cities, and Districts, and for the Irrigation of Coffee, Cotton, Indigo, Sugar-cane, and Rice Estates, for pumping out Coffer-dams, Canals, Dry Docks, Reservoirs, &c. They also manufacture and supply the Pumping and other Machinery for Paper, Pulp, and Fulling Mills, Breweries, Distilleries, Tanneries, Starch Works, Bleaching, Dyeing, and Calico Printing Works, Chemical Works, Silk, Cotton, and Flax Mills, and Manufactories in general. All Letters not paid will be refused. Illustrated Price Lists forwarded on receipt of Six Postage Stamps.—GWYNNE AND Co., Hydraulic and Mechanical Engineers, Essex-wharf, Strand, London.

For Exportation.—The above can be obtained through British Merchants, Shippers, and Colonial Agents. (34)

Digitized by Google

TO STEAM SHIP OWNERS, ENGINEERS, AND OTHERS.

How's Patent Steam Engine Counters, can be read at sight.

These Counters register the number of revolutions made by an engine or other mechanism. They may be used for ascertaining the duty of Pumping Engines and Water-wheels; the revolutions on board a steam-vessel; to calculate the slip of the propeller; and in a locomotive to test the slip of the wheels.

How's Patent Salinometer, for Steam Boilers using Salt Water.

By these, the density of the water in the Boiler is at all times accurately shown, and a saving of boiler and fuel is effected. They are adopted by the Admiralty, the Honorable Trinity Corporation, and others. Copies of Testimonials from Messrs. Penn, Messrs. Maudslay, and others, will be forwarded on application.

How's Engine-Room Telegraph, for communicating between Captain and Engineer. Society of Arts Prize Medal, 1855.

This is a Mechanical Telegraph, and by its peculiar construction, error or misunderstanding is rendered impossible. It is now extensively adopted, and gives great satisfaction.

How's Patent Fresh Water Apparatus for Ships' Use.

This apparatus is designed for the distillation of Fresh from Salt Water; and on long voyages, and where the supply of water is scanty, it will be found invaluable. Testimonials may be seen.

Patent Steam Pump and Fire-Engine for Ships' Use.

This Steam-pump occupies but a small space; works perfectly noiselessly, and throws an immense volume of water. An Illustrated Circular of Fresh Water Apparatus and Steam-pump combined, free on application.

How's Patent Machine for Cutting Bolts, Rods, Spindles, Wire, &c.

Simple in construction, inexpensive, occupies but little space, and will not easily get out of order.

A Pamphlet Illustrative of the above, sent free by post, on application to

A. P. HOW, ENGINEER,
81 MARK LANE, LONDON.

EVERY DESCRIPTION OF ENGINEERS' TOOLS, ENGINE ROOM STORES, &c., &c., SUPPLIED.
(80)

SCOTT'S
PATENT GRASS SEED SEPARATOR,

which entirely extracts the Seeds of "COUCH," "TWITCH," "SPEAR," or "HAIR" GRASS, and other impurities from

PERENNIAL AND ITALIAN RYE-GRASS, &c.,

AND

SCOTT'S PATENT CARROT SEED BEARDING

AND

CLVER AND TREFOIL MILLING OR DRAWING MACHINE,

which effectually removes the beard from Carrot Seed, rendering it fit for sowing with facility by drill or otherwise, and by the separation of abortive or diseased grains vastly increases its vegetative per centage. By a slight modification it is applicable to the other purposes before mentioned.

These Machines were admittedly the most novel, and, at the same time, the most useful and important to the Farmer of any exhibited at the late SMITHFIELD CLUB SHOW.

They may be seen at work at the Establishment of the Manufacturer,

Mr. T. MIDDLETON, Engineer, Southwark.

Communications to be sent to the Patentee, J. SCOTT, 111 Drummond Street, Euston Square, London, N.W.
(18.)

THE ROYAL AGRICULTURAL SOCIETY OF ENGLAND'S
FIRST PRIZE REAPER.

BURGESS & KEY, PATENTEES AND SOLE MAKERS, 95 NEWGATE STREET, LONDON.

MANUFACTORY, BRENTWOOD, ESSEX.

BURGESS & KEY'S extensive Manufactory is wholly occupied in the Manufacture of

REAPING MACHINES AND GRASS MOWING MACHINES,

upon which they have concentrated their efforts since the year 1851. Their practical experience enables them to produce Reaping Machine which can be depended on by the Farmer.

Owing to the excessive demand for last season, many orders were left unexecuted. BURGESS & KEY therefore earnestly request that orders for next season (1859) be sent as soon as possible, otherwise they cannot guarantee to deliver in time.

Price £42 10s. Net Cash, at the Works, complete with Conical Screw Divider for long Grain; without the Conical Screw, £40. Extra Knife, £1 5s. If other extras are supplied they are charged for. A man sent to start the Machine, if required, on payment of his expenses.

BURGESS AND KEY'S GRASS-MOWING MACHINE
(ALLEN'S AMERICAN PATENT).

Before introducing this Machine to the English public, BURGESS & KEY determined to fully test its capabilities, and the all-important point—durability. One Machine cut, on the farm of Mr. C. Hall, Havering, Romford, Essex, 83 acres Grass; and the same Machine afterwards cut, on the farm of Mr. Tabrum, Bovis Hall, near Brentwood, Essex, 100 acres Grass, and 20 acres Clover. The work done was declared to be better and lower than the scythe, and at the rate of 1 acre per hour. Orders have been received from both those Gentlemen, and numerous others, for Machines for next season. Price £30.

BURGESS & KEY'S Manufactory is entirely devoted to REAPING MACHINES and MOWING MACHINES.

95 NEWGATE STREET, LONDON.—MANUFACTORY, BRENTWOOD, ESSEX.

FURTHER PARTICULARS AND CATALOGUES SENT ON APPLICATION. (39)

By Her Majesty's Royal Letters Patent.

E. DENCH,

KING'S ROAD, CHELSEA, AND HAMPSTEAD ROAD,

Patentee and Sole Manufacturer of

PATENT

GALVANIZED-IRON HOT HOUSES AND CONSERVATORIES,

Has Two SPAN ROOF HOUSES left for Sale, a Great Bargain!

PATENT HOT HOUSES

every way superior to any other Material, at 1s. 3d. per ft. super, with excellent heavy, good quality GLASS.

PRINTED PRICE LIST SENT ON APPLICATION.

HEATING BY HOT WATER with efficiency and economy.
(83)

GLENFIELD PATENT STARCH,

USED IN THE ROYAL LAUNDRY,

AND PRONOUNCED BY HER MAJESTY'S LAUNDRESS TO BE THE FINEST STARCH SHE EVER USED.

WHEN YOU ASK FOR

GLENFIELD PATENT STARCH,

SEE THAT YOU GET IT,

as inferior kinds are often substituted.

Sold by all Chandlers, Grocers, &c., &c. (75)

ANDREW McLAREN and CO.,

ENGINEERS AND IRONFOUNDERS,

174 UPPER THAMES STREET.

MAKERS of all kinds of CAST IRON PIPES for Gas, Water, and Steam, and every description of Castings. (115)

RANSOME'S PATENT IMPERISHABLE SILICIOUS STONE.—Chimneypieces, Balustrades, Capitals, Trusses, Terminals, Fountains, and Vases; also, Enamelled Stone Chimneypieces, of great beauty and novelty, at reduced prices. Monumental or Mural Memorials, Grave Stones, Space Markers, and Indicators for Cemeteries, &c., of every description, at the lowest price.

RANSOME'S PATENTED PROCESS FOR PRESERVING STONE.—Invaluable in its application to Public Edifices and Private Residences. By this process the softest and most friable stone can be rendered impervious and imperishable, and decay at once arrested and prevented.

RANSOME'S PATENT STONE FILTERS FILTERING SLABS.—Manufactured for every Private or Domestic purpose, for Manufactories, Public Companies, Shipping, &c. Several hundred thousand gallons of water are filtered daily by Ransome's Patent Stone Filtering Slabs, for the town of Southampton. They have also been adopted by the Admiralty, the Board of Ordnance, the Colonial Land and Emigration Commissioners, and other Public Bodies for several years; also in the City of Rotterdam, with the most perfect success.

For particulars, specimens, illustrations, and agencies, apply to

Mr. FREDERICK RANSOME,
WHITEHALL WHARF, CANNON ROW, WESTMINSTER;
OR PATENT STONE WORKS, IPSWICH.

A liberal discount allowed to the Trade or to Shippers.
(14.

A NEW DISCOVERY IN WASHING HOUSEHOLD LINEN.

NO FAMILY SHOULD BE WITHOUT HANCOCK'S UNIVERSAL WASHING MACHINE. It effectually cleanses the Crevices of Baby-linen, Collars, Wristbands, &c., without the possibility of injuring the Linen or Collars. Received 500 Testimonials.

PRICES.

No. 2 Washes 9 Shirts in from 3 to 10 minutes; or 4 Sheets in 5 minutes - - - - -	£5 5 0
No. 3 Washes 12 Shirts in from 3 to 10 minutes; or 6 Sheets in 5 minutes - - - - -	7 11 0

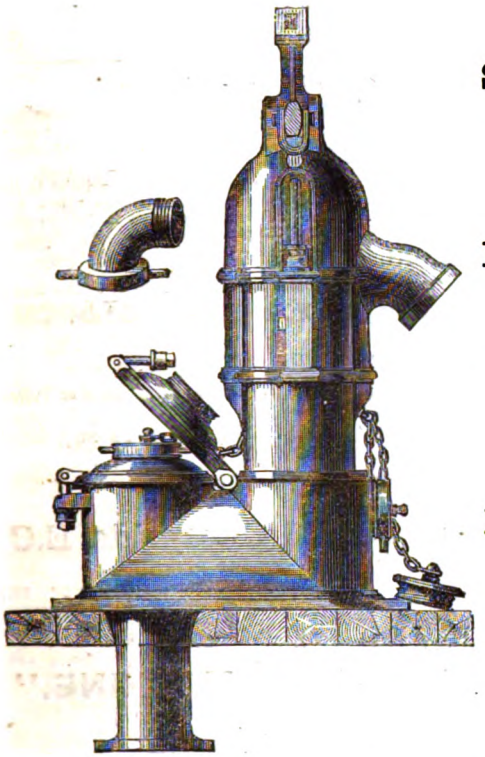
T. SUFFIELD AND CO.

Call the particular attention of

SHIP-OWNERS, SHIP-BUILDERS, AND COMMANDERS OF STEAM AND SAILING VESSELS

to the Simple and Efficient Arrangements of their

PATENT PUMPS.



Ships' Pumps

AND

Fire Engines,

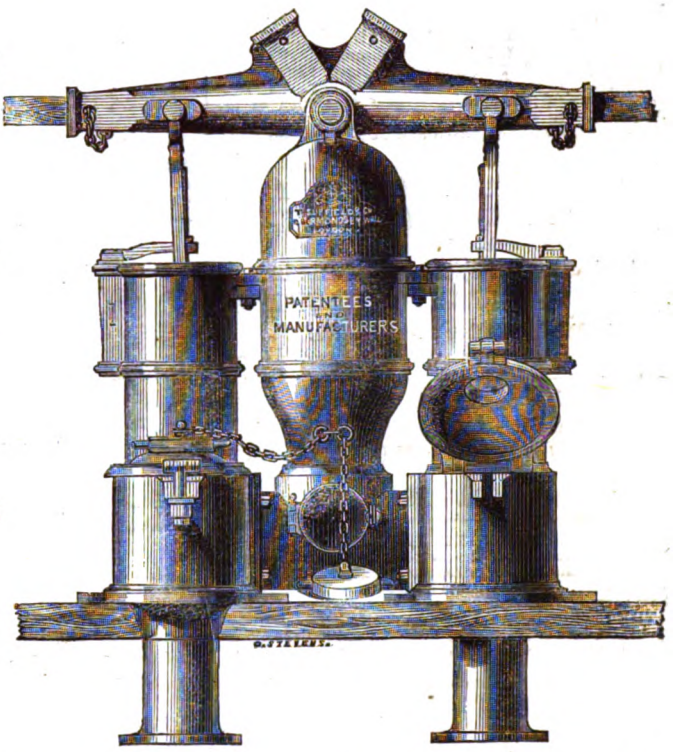
Fixed and Portable,

WITH

Patent Valves

AND OTHER

Improvements.



These Pumps are free from that liability to choke which is common to other Pumps, and their Working Parts are not susceptible of derangement either from wear or from being long out of use. They pass entirely through them, with ease, any substance that may enter the Suction Pipes. The Novelties in these Pumps are their adaptation to the varied duties of Ships' Pumps, the facilities they afford for Cleansing the Suction Pipes, and for Sounding or Examining the Valves; the readiness with which they may be used for Ventilating the Bilge, or for acting as a Syphon either for Watering the Ship, or for extinguishing Accidental Fires on board; the rapidity with which they can be converted into Fire Pumps, or be applied to the Washing of Decks; and their capability of Pumping from Several Compartments.

T. SUFFIELD AND CO.

Also respectfully solicit the attention of STEAM SHIP BUILDERS and OWNERS to their Large and Varied STOCK of

ASSORTED STORES FOR MARINE PURPOSES.

They keep a Large Stock of Goods, of their own Manufacture and from the Best Makers, constantly on view; so that by a visit to their Works or Depôt, much valuable time may be saved by Managers, Engineers, and other Gentlemen who may require such Stores, together with a further saving in the cost of such Articles.

DEPOT, 116 FENCHURCH STREET, E.,

(OPPOSITE MARK LANE.)

THE LITERARY AND
EDUCATIONAL YEAR BOOK
FOR 1859.

THE LITERARY AND EDUCATIONAL YEAR BOOK contains a Catalogue of the Books published in 1858, with the name of the author, price, size, binding, and publisher of each book. Also the names and addresses of the London Publishers.
THE LITERARY AND EDUCATIONAL YEAR BOOK contains a list of the principal American and Foreign Books published in 1858, with the name of the author, price, size, binding, and publisher of each book.
THE LITERARY AND EDUCATIONAL YEAR BOOK contains a list of the works printed by order of the Commissioners of Patents for Inventions, including chronological indices and classified abridgements of all specifications of patented inventions and the Free Libraries and Institutions where new works, including 1,000 volumes, may be consulted.
THE LITERARY AND EDUCATIONAL YEAR BOOK contains lists of the new Maps and Prints published during 1858, with the size, price, and publisher of each.
THE LITERARY AND EDUCATIONAL YEAR BOOK contains lists of all the Metropolitan and Provincial Newspapers, stating where each paper is published, when it was established, its peculiar politics or principles, day of publication, and price.
THE LITERARY AND EDUCATIONAL YEAR BOOK contains the names and addresses of all the principal Newspapers in all the great towns and cities of the Continent; also those published in the British Colonies and the United States of America.
THE LITERARY AND EDUCATIONAL YEAR BOOK contains lists of all the Weekly, Monthly, and Quarterly Publications of the Metropolis and the Provinces, stating when and where each is published, and price.
THE LITERARY AND EDUCATIONAL YEAR BOOK contains the Learned, Philosophic, and Artistic Societies of the Metropolis, stating the nature and object of each Society, with the names of the Officers of each, the papers read before each in 1858, and all the necessary information about conditions of membership, entrance fees and annual subscriptions, days of meetings, &c.
THE LITERARY AND EDUCATIONAL YEAR BOOK contains the Public Metropolitan Libraries and Museums, and Lists of the Metropolitan and Provincial Schools of Art and Science, with the names of the principal promoters and teachers of each school.

NEW PERIODICAL.

On the first of March next will be published, price 6d., No. 1 of the LITERARY RECORD, a new monthly periodical, to be conducted on a new principle, and which will differ from every existing periodical as much as chalk from cheese! The LITERARY RECORD will, to all intents and purposes, supply a want, and will be found a *vade mecum* for Authors, Editors, Journalists, Artists, and the whole Book-making, Book-selling, and Book-reading public. If the proprietor's idea be realised—and there is no reason why it should not—then the LITERARY RECORD will become the constant companion of every public Reading-room, Editor's-desk, and Bookseller's-counter in the country.

London; KENT & CO., Paternoster Row, and Fleet Street. (100)

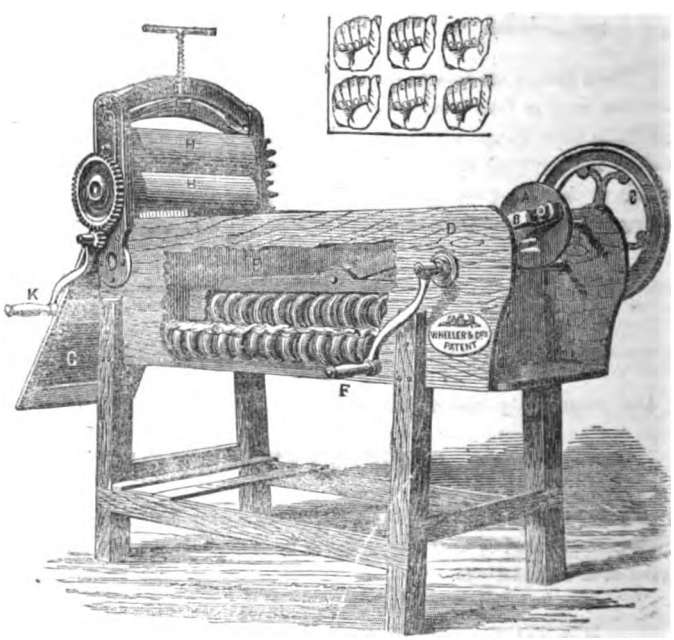
HOBBS'S LOCKS.

The attention of Architects and Builders is respectfully invited to
HOBBS'S NEW MORTISE LOCKS,
Which are now manufactured by PATENT STEAM MACHINERY, and, while superior to any other locks in the market, are sold at a price which defies competition. The Plates are made of number "Twelve Gauge" Iron, and being so thick, the pins cannot be loosened by the constant jarring of the door. The security consists in four double-acting levers, while, to secure unusual freedom of motion and prevent the wear of the parts,
HOBBS'S PATENT FRICTIONLESS FOLLOWER
is also applied. The retail price of these Locks is 10s., from which a liberal discount is allowed to the trade.
HOBBS'S NEW MORTISE LOCKING LATCHES FOR STREET DOORS,
Price 18s. And
HOBBS'S NIGHT LATCHES, RIM OR FLUSH, PRICE 10s.,
Are also recommended, together with every description of Lock required for house and cabinet work. Lists of Prices will be forwarded on application, post free.

N.B.—A complete Assortment of FIRE and BURGLAR-PROOF SAFES (Milner's Patent), fitted with HOBBS'S PATENT PROTECTOR LOCK, POWDER-PROOF.
ALSO, STRONG-ROOM DOORS, CASH AND DEED BOXES, ETC.

Address—Hobbs, Ashley, and Co., 76 Cheapside, E.C.
MANUFACTORY, ARLINGTON STREET, NEW NORTH ROAD.
(86)

T. WHEELER AND CO.'S
"OXONIAN KNUCKLE WASHING MACHINE."



THE Improvements in these New Inventions are the non-exposure of the user's hands to the dangerous parts of the Machine, and the rapidity with which the work is done. These Machines have neither bands or wheels passing on the outside, wherein lies the liability to accident. The rubbers are the truest representation of the knuckles or hand washing yet brought out; the compensating floating rubbers work at right angles, backward and forward, in the same manner as does the hands. These Machines can be supplied with rubbers that represent a person's hand in the action of rubbing; the knuckles, finger nails, and palm of the hand being truly modelled. They are capable of Washing Clothes of every description whatsoever, the largest bedding to the most delicate piece of muslin can be washed without breaking a single thread; in fact, such is the delicacy of the action of these Machines, that the paper you are now reading can be passed between the rubbers without sustaining any injury, at the same time being thoroughly effective in cleansing. The Patentees confidently recommend these Machines to the notice of Laundresses, Heads of Families, Hotels, Emigrants, &c. So simple is the action of this Machine, that a boy or girl of 10 or 12 years of age can work it; the only skill required is to soak the clothes one hour before placing them in the Machine, placing a portion of the clothes at the handle end of the Machine; laying on the rubbers a part of them; turn the handle, and the clothes will pass through between the rubbers to the opposite end, effecting a saving of at least 50 per cent.

Prices: Washing Machines, £1 6s., £2 6s., £3 6s., £4 10s., £5 15s.; Washing, Wringing, and Mangling, £8 8s., £10 15s., £14 14s.—Full Instructions sent with every Machine. Testimonials or References sent on application.

MANUFACTORY, ALBION WORKS, PARK END STREET, OXFORD. (114)

NOTICES.

Numbers 1845 and 1846 of the MECHANICS' MAGAZINE (original series), containing the paper read at the Society of Arts, Dec. 15, 1858, "ON THE MODIFICATIONS WHICH THE SHIPS OF THE ROYAL NAVY HAVE UNDERGONE DURING THE PRESENT CENTURY IN RESPECT OF DIMENSIONS, FORM, MEANS OF PROPULSION, AND POWERS OF ATTACK AND DEFENCE," by one of the EDITORS of this Magazine, together with the discussion on the same, are still on sale.

The MECHANICS' MAGAZINE will be sent free by post to all subscribers of £1 1s. 8d., annually, *payable in advance*. Post Office Orders to be made payable to R. A. Brooman, at the Post Office, Fleet Street, London, E.C.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 6d. per line for any number of insertions less than 13; for 13 insertions, 5d. per line; and for 52 insertions, 4d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

Special Arrangements for larger or Serial Advertisements. To ensure insertion, Advertisements must reach the Office by 6 o'clock on Thursday evening each week. None can be received after 9 o'clock on Friday morning for the ensuing number.

TO CORRESPONDENTS.

We have to ask for the patience of several correspondents whose communications are unavoidably left over till next week.

REMARKS.—We have had a quiet market for Metals during the week. The continued anxiety felt respecting political affairs having had a depressing effect on business.

LAWRIE AND HAGGER, Metal Brokers.

33 Lombard-street, E.C.

LIST OF MISCELLANEOUS TENDERS INVITED, AND ENGAGEMENTS OPEN.

RAILWAY WORKS, *India*.—For the Nangpore branch of the Great Indian Peninsular Railway, 262 miles in five contracts. Particulars at offices, 3 New Broad Street. Tenders before February 4.

RAILS, *Paris*.—For a supply of rails called "*Vignolle*." Conditions, &c., at 99 Rue Richelieu, Paris. No date given.

WHEELS AND AXLES, *South-Eastern Railway*. — For 300 sets of Wrought Iron Waggon Wheels and Axles. Further particulars of Mr. E. Fletcher, Locomotive Works, Gateshead. Tenders to the Secretary, (Mr. J. Cleghorn, York,) to February 2.

IRON BRIDGES, *Brighton and South Coast Railway*.—For the construction, delivery, and fixing of all the wrought and cast-iron girder bridges to be erected upon new branch line from Shoreham to West Grinstead, Sussex, ten miles. Drawings, &c., at Engineer's office, London Bridge Terminus. Tenders on prescribed form, till noon, February 10, to Mr. F. Slight, Secretary, London Bridge Terminus.

PASSENGER STATIONS, *Darlington*.—The directors of the North-Eastern Railway will receive tenders for erection of a Passenger Station, with iron shed roof, at Darlington. Plans, &c., with Mr. T. Prosser, architect, Central Station, Newcastle-on-Tyne. Tenders addressed to the Secretary not later than 12 at noon, 17th February next.

Scarborough.—The directors will receive tenders for an Iron Shed Roof and other works, at Scarborough Station. Plans, &c., with Mr. T. Prosser, as above; and tenders by noon, 3rd February.

RAILWAY FENCING, *Stratford-upon-Avon*.—For supplying about 20 miles of good sound larch post and rail fencing, to be fixed on a proposed line from Hatton to Stratford-upon-Avon. Specifications, &c., at Messrs. Banson and Gwyther's offices, Belmont Row, Birmingham. No date.

PIG LEAD, *India Board*.—The Finance, Home, and Public Works Committee, invite proposals from persons willing to supply Pig Lead. Conditions at the Secretariat Office, at the India House, where the proposals are to be left before 11 forenoon, 4th February, 1859.

GAS LAMPS, *Norwich*.—For providing and erecting about 800 gas lamps, on columns and brackets. Specifications, &c., at the office of City Surveyor, 24 Castle Meadow, Norwich. Tenders to February 3.

BUILDING, *Rainhill*. — The committee of visitors of the County Asylum for the hundred of West Derby, Rainhill, near Prescot, will receive tenders for the erection of two additional wings to that Institution. Plans at the office of the architect, Mr. H. P. Horner, 10 Basnett-street, Liverpool, till Feb. 9th, inclusive; and at the Asylum, as above, from Thursday, Feb. 10th, to Friday, Feb. 18th, inclusive; and bills of quantities, prepared by Mr. John Longrigg, Lord-street, Liverpool, and forms of tender will be delivered to parties leaving their names, as purposing to tender, at the architect's office, or at the Asylum, on and after Tues., Feb. 1st, 1859.—The contract will be taken on a single sum, and each tender must contain the names of the several sub-contractors proposed for the different branches of the work, and the signatures of two sureties. Tenders at No. 10 Sweeting-street, Liverpool, on or before Sat., 19th of Feb., 1859, by twelve at noon; or at the Asylum, on or before Mon., 21st Feb., by ten forenoon, to Mr. T. Martin, solicitor, clerk to committee of visitors.

CEMETERY, *Borough of Hanley*.—Contract for erection and finishing of the mortuary chapels, registrar's house, porter's lodge, and gates, for this cemetery. Plans, &c., at offices of Messrs. Ward and Son, architects, Hanley Tenders, to the offices of the town clerk before Fri., 11th Feb. Contract for making and constructing the road, and for the drainage and sewerage of the cemetery. Plans, &c., at office of Mr. Forbes, Shelton Hall. Separate tenders for the road, and for the drainage and sewerage, at the town clerk's office, on or before Fri., 18th Feb.

SCHOOLS, &c., *Wakefield*.—For the erection of Catholic Schools at Wakefield. Plans, &c., at the office of Messrs. Harrison and Nettleton, Solicitors, Wakefield, on and after January 31. Tenders to February 14.

Derbyshire.—New Schools and Master's House at Sawley. Plans, &c., at the Parsonage. Tenders to February 8.

Rossall.—Tender for whole works or several works required in erecting a New Wing to the Rossall School Buildings, containing studies, dormitory, master's rooms, and class room. Plans, &c., at the Bull Inn, Preston; further information from C. G. Harvey, Esq., Bursar, Rossall, Fleetwood. Tenders to Mr. Harvey, on or before February 14.

ROADS, *Powick District*.—For improvement on turnpike-road from Worcester to Malvern, by lowering the hill in the village of Powick, Worcester. Plans at office of Mr. M. Curtler, Sansome-place, Worcester. Tenders to Feb. 1.

Leicester and Peterborough.—For repairs of Leicester district of the road, about 700 tons of the best picked broken granite, to be delivered between 1st March next and the last February following. The trustees will also receive tenders for carriage or haulage of the granite into parishes as may be directed, and for other team-labour and haulage required between the 1st March next and last February following. Terms, &c., with Mr. C. A. Macaulay, surveyor of district, office, Friar-lane, Leicester. Tenders to February 7.

Market Harborough, Loughborough, and Melton Mowbray. —For supplying surveyor of turnpike-roads of these places with about 1,800 tons of broken granite, or part thereof. The carriage of such granite, or part thereof, from wharfs to turnpike-roads. Tenders to chairman of trustees of said roads. Terms, &c., at office of Mr. M. J. Dain, surveyor, St. Martin's, Leicester. Tenders to February 7.

Hinckley and Narborough, Ashby-de-la-Zouch.—For supplying surveyor of above turnpike-roads with about 2,000 tons of broken granite, or part thereof. The carriage of such granite, or part thereof, from wharfs to turnpike-roads. Tenders, &c., as above mentioned. The terms, &c., at the office of Mr. C. A. Macaulay, surveyor of roads, Friar-lane, Leicester. Tenders to February 7.

LEVELLING GROUND AND ERECTING BUILDING, *Worcester*. —Contract 1: For removing turf from one acre of land (Worcester Pleasure Grounds Company) levelling surface, and relaying turf for a cricket ground. Contract 2: For erecting a span-roofed propagating house for plants, 40 ft. by 12, of brick, wood, and glass; and finishing the same with apparatus for heating it with water. Specifications, &c., Mr. H. Strange, Hon. Sec., 42 Foregate-st., Worcester. Tenders to Jan. 26.

TOLL HOUSE, *Malvern*.—For building a toll-house on the Powick district of turnpike roads, at the Twelve-mile Gate, Little Malvern. Plans, &c., at the office of Mr. M. Curtler, Sansome-place, Worcester. Tenders to Feb. 1.

PIG PENS, *Leeds*.—Tenders to Feb. 1 for providing and fixing pig pens, of iron and wood, in the Kirkgate Market, Leeds; also for painting the market bye-laws on boards, and fixing the same. Plans, &c., at the office of Mr. Ed. Filliter, C.E., Borough Surveyor, Town-hall, Leeds.

TAR, *Chester-le-Street*.—The Birtley Iron Company will receive offers for the purchase of the tar at their Gas Works. The tar can be delivered either on to North-Eastern Railway, or at Pelaw Main Staith in the Tyne. 300 to 400 barrels a-year. Parties tendering to find their own barrels.

SANITARY PIPES, *Cashel*.—Wanted by Town Commissioners for city of Cashel, 10,200 feet of piping, of some 3, 4, and 5-in. diam., and from 2 to 3 ft. in length, free from flaws or warps, and perfectly sound. Applications before 1st Feb., stating price per foot, delivered in Waterford, to Mr. John Corby, Town Clerk.

WATERING STREETS, &c., *London*.—Watering the roads and streets in Limehouse district. Particulars, upon payment of 2s. 6d., by application at office of the Board, White Horse-street, Commercial-road, E. Tenders to Feb. 7.

TIMBER, *Eastern Counties Railway*.—The Directors of this Railway will receive tenders for supply of 2,000 loads of Memel timber at Lowestoft. Forms of tender, &c., with the Eng. of the Company, London. Tenders to the Sec., J. B. Owen, Bishopsgate terminus, by 1st Feb.

TRAMWAY, *Portsmouth*.—Tenders for constructing a tramway at the Gun-wharf, Portsmouth, will be received at office of Director of contracts, War-department, Pall-Mall, London, on Monday, 14th Feb. Plans, &c. at the Royal Engineer's office, Portsmouth, from 10 till 4 o'clock, until 12th Feb.

BUILDING AND DRAINAGE, *Lymington*.—Generally repairing and decorating, making various alterations, reconstructing drainage, &c., at Newtown-park Mansion, near Lymington, Hants. Plans, &c., with Mr. Hill, Surveyor, Southampton, to whom tenders must be sent by Feb. 12.

GULLEY GRATINGS, *London*.—The Vestry of Bethnal Green will meet at the Town Hall, Church-row, Bethnal Green-road, at 11, on Feb. 3, to receive tenders for 150 cast-iron gully-gratings, according to pattern to be seen at office of Surveyor at Town Hall. Tenders to Clerk of Vestry by Feb. 2.

GRANITE SPALLS, *London*.—The Vestry of the Hamlet of Mile End Old Town, will meet at the Town House, Mile End-road, on the 2nd Feb., at 7 p.m., to receive tenders for supply of 500 tons of unbroken best blue Guernsey granite spalls, to be delivered alongside Gardner's-wharf, Regent's-canal, Mile End-road, according to the terms of a specification which may be seen at office of Surveyor at Town House, between 10 and 1. Contractors to pay for the contract to be drawn up by the Clerk, and to find two sureties. Tenders by 3, at the office of the Clerk to the Vestry, Feb. 2.

FARM, *Scotland*.—To erect a complete farm-steading on the farm of Woodend, parish of Langton, Berwickshire, conform to plans, &c., now with the farm-overseer, Woodend. Offers to be addressed to Messrs. Davidson & Lyme, W.S., 22 Castle-st., Edinburgh. No date.

NEW CONGREGATIONAL CHAPEL AND SCHOOLS, *Eccles, Manchester*.—Plans, &c., on and after Wed., 9th of Feb., by application to Messrs. Dilworth and Son, New Market Hall, Cross-street, Manchester, between ten a.m. and four p.m. Tenders to be at Messrs. Dilworth's not later than Tues., 22nd Feb, at three p.m. Information by application to architects, Messrs. Poulton & Woodman, Reading.

ARCHITECTS' COMPETITION, *Wales*.—The time for sending in the designs for a new chapel for the Calvanistic Methodists at Aberystwith is extended to the 1st of March next. The gallery, if hereafter required, is to be over both sides and one end of the building.

WORKING QUARRIES, *Newcastle-upon-Tyne*.—The Working to let of a large quantity of Limestone and Quarry Baring, at the Fourstone Lime Quarries. Particulars at the office, where tenders will be received until Feb. 7.

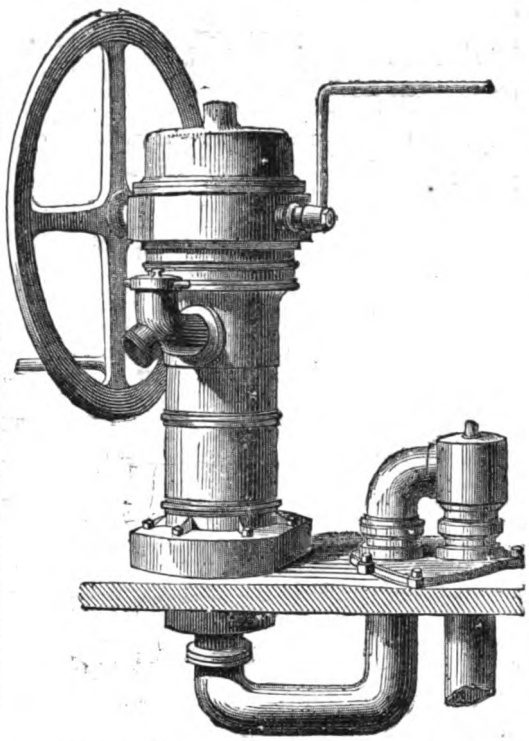
Under the Patronage of the Board of Admiralty.

SHIPS' PUMPS OF HER MAJESTY'S NAVY.

JOSIAH STONE,

Sole Manufacturer of DOWNTON'S well-known and much approved SHIPS' PUMPS, which have been used in preference to all others on board the vessels of Her Majesty's Navy, for upwards of thirty years, and have given the greatest satisfaction, effectually answering all the purposes required of any Ships' Pumps, and capable of throwing most powerful jets of water in case of fire.

These Pumps have also been most extensively used on board merchant vessels, both at home and abroad, and have been supplied to the Royal Navies of France, Prussia, Holland, Russia, Spain, and Turkey. The Pumps are portable, as they may be easily removed from the ship and put to work in a boat alongside in a few minutes. Each pump is fitted with a large foot valve plate (which may be placed in any part of the vessel most convenient), and from which communication is made to any number of distinct compartments in the vessel. In case of any of these pipes fouling, the water, by an almost momentary attachment, may be forced from the Pump downwards, so as to clear all obstructions, preventing any possibility of stoppage. The valves are of the simplest description, and being faced with ordinary leather discs, the latter may be renewed in a few minutes by the most inexperienced hands. By the peculiar construction of these Pumps, a most perfect and uninterrupted flow of water may be maintained; so uniform as to be undistinguishable from that proceeding from a cistern. The Pumps are made of several sizes, those of 7, 9, and 12 inches bore being most generally used. They may, however, be ordered of any dimensions required, and may be fitted either with one or two fly wheels. A standard, &c., is also supplied with these Pumps, to enable them, when necessary, to be used as ordinary hand-lever pumps.



JOSIAH STONE, Engineer, Manufacturer of all descriptions of PUMPS and FIRE ENGINES for Land and Ships' Use; Brass and Iron Founder and Finisher, Nail and Rivet Maker, &c.

CONTRACTORS FOR FIRE-ENGINES, ETC., TO THE WAR DEPARTMENT,

RAILWAY STATION, DEPTFORD, AND 12 GARLICK HILL, CITY, E.C.

PIERCE'S

UNRIVALLED

PYRO-PNEUMATIC FIRE-LUMP WARMING AND VENTILATING STOVE GRATES,

WITH the cheerful, open fire, producing healthful warmth, with continuous Self-acting Ventilation, for Churches, Schools, Public Buildings, Banking Houses, &c. These Grates are manufactured solely by PIERCE, the Inventor, for which he received the Prize Medals of London in 1851, and of Paris in 1855.

PRICE, from £7 10s.

ILLUSTRATED CATALOGUE, with Prices and Estimates for Work, furnished on application to the Inventor and Sole Manufacturer.

Also his

IMPROVED COTTAGER'S GRATE,

For Warming Two Rooms with only One Fire. Prices, 30s. and 35s.

PIERCE, No. 5 JERMYN STREET, REGENT STREET.

(111)

TO BRASS-FOUNDERS, ENGINEERS, &c.

THE PATENT PLUMBAGO CRUCIBLE COMPANY having completed the enlargement of their premises, beg to call the attention of all users and shippers of Melting Pots to the great superiority of the PATENT CRUCIBLES, which have been used during the last three years by some of the largest melters in England and abroad. In addition to their capabilities of melting an average of from thirty-five to forty pourings; they are unaffected by change of temperature, never crack, but can be used till worn out, requiring only one annealing for several days' work, and become heated much more rapidly than ordinary pots, effecting thereby a saving of more than fifty per cent. in time, labour, fuel, and waste. The Patent Plumbago Crucible Company also manufacture and import clay crucibles, muffles, portable furnaces, sublimate pans and covers, glass-pots, all descriptions of fire-standing goods, and every requisite for the assayer and dentists. For Lists, Testimonials, &c., apply to Battersea Works, London, &c. (43

PUMPS

FOWLER & Co.

WHITEFRIARS STREET, FLEET STREET,

— LONDON. —

HYDRAULIC MACHINERY OF EVERY DESCRIPTION, FOR HOME USE OR EXPORT, UPON THE LARGEST, OR SMALLEST SCALE, MANUFACTURED, FIXED, OR LENT ON HIRE: AN EXTENSIVE STOCK KEPT READY FOR GENERAL PURPOSES.

HIGH-PRESSURE VALVE-COCKS, LAMBERT'S PATENT.

Equilibrium Ball Valve. Cottage Closet Valve.

The Equilibrium Ball-Valve is simple and certain in its action, and is cheaper than the common cocks now in use.

The Cottage Valves are suitable for application to any kind of basin; and, as they shut against the pressure, no concussion in the pipes can possibly occur.

These cocks have been extensively and most successfully used in many towns, under continuous high pressure, varying from 100 to 350 feet; their efficiency and durability is, by experience, established.

THOMAS LAMBERT and SON,
Brass Founders, Short-street, New-cut, Lambeth.

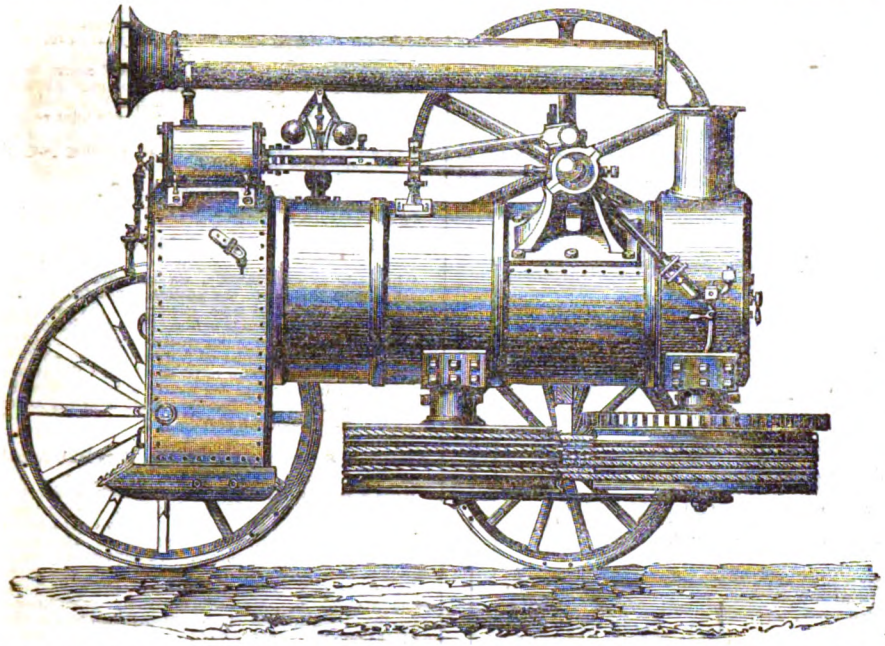
COLLINSON HALL'S PATENT WINDLASS
AND
STEAM PLOUGH AND IMPLEMENT GEAR.



The object of this mechanism is to render effective the WHOLE POWER of engines used in drawing ploughs or other implements in tilling land. This is accomplished by carrying the wire rope, in the form of the figure 8 round horizontal drums fixed (so as to be easily removable) under the engines. By this arrangement the evils arising from overlaying the coils of rope when wound upon the capstan principle are avoided, as also are those arising from an unequal wear of the ordinary horizontal pulleys. In the new arrangement the solid drum is constructed with several grooves, while the other is composed of as many independent pulleys as there are grooves in the drum. The upper or lower pulley, as the case may be, revolves in one direction, while the remaining ones revolve in the opposite direction. The solid drum only is driven directly by the engine, while the pulleys revolve by frictional contact, and thus all slipping is avoided.

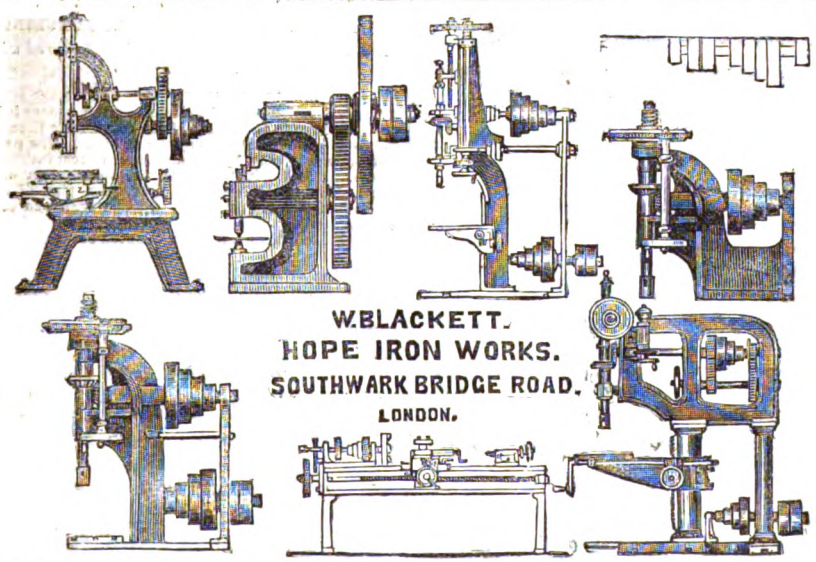
The simplicity of this Gear is one of its chief recommendations, little or no framing being required. The axes being bolted to the bottom of the boiler, a simple rod or beam retains them in a vertical position. The Gear may be fitted and again unshipped from an engine (by means of keys through the axes, by which the Gear is retained in place) in less than ten minutes.

COLLINSON HALL respectfully informs Agricultural Engineers that he has disposed of his interest in the above Patent to

MR. J. FOWLER, JUN., 28 CORNHILL,

To whom Applications for Licences must in future be made.

(53)



W. BLACKETT has in Stock a variety of Vertical and Horizontal Steam Engines, Boilers, and Engineers' Tools, ready for delivery on the shortest notice. Apply as above.

Beware of spurious imitations.

(49)

VENTILATION WITHOUT FLUE.

KUKLA'S PATENT STOVES, at 18s., 25s., and 50s.

KUKLA'S newly-invented Deflagrator—the first and only perfect GAS STOVE. Guaranteed to burn without flue—without dust, smell, or smoke, producing a great and pure heat with the least expenditure of Gas.—*Vide Society of Arts' Journal.*

Patronised by the English and French Government.

Scientific in Principle,
Simple in Construction,
Healthy and efficient in use.

The Deflagrator Stove is cheap, portable, and suited for every situation; and from the principle on which it is constructed (viz., expanding to a sixfold volume the gas used) is capable of warming any given space more quickly and more thoroughly than any other means: while its addition forms a sure remedy for any ill-warmed or ill-ventilated apartments.

The 25s. Deflagrator warms a room of 2,000 cubic feet at a cost of 3d. per day.

The 50s. Deflagrator warms 5 to 6,000 cubic feet at a cost of 6d. per day (twelve hours). Also, the Greenhouse Stove at 18s.

Patentee and sole Manufacturer, F. X. KUKLA, 194 Pentonville-road, London.

Country orders promptly attended to. Carriage free to any Railway in London. Post-office Orders should be made payable to FRANCIS XAVIER KUKLA, General Office.

N.B.—Every Stove separately tested before sent out.

The NEW GAS COOKING STOVE for 10 persons, price £3.

THE LONDON

WARMING AND VENTILATING COMPANY,

(LIMITED,)

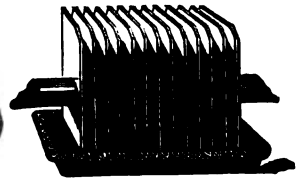
36 GREAT GEORGE STREET, Westminster, S.W.

(MANAGER—Mr. WOODCOCK.)

Churches, Greenhouses, Offices, and Buildings of every description warmed by means of a modification of the plan successfully used during the last five years by Mr. Goldsworthy Gurney in both Houses of Parliament.

Steam, Hot-water, Gas, and in open or enclosed fireplaces, Coal and Coke are equally available for the process.

The cost is less and the effect greater than that of any other known means.



The Horticulturist will find herein an instrument of new and important powers.

The apparatus may be seen in ST. PAUL'S CATHEDRAL, the various offices of the "Department of Science and Art," and in many churches and other buildings.

Particulars and Testimonials forwarded on application.

(12)

CLAYTON, SHUTTLEWORTH, AND CO.,

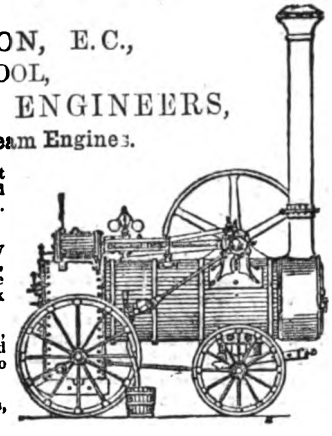
OF LINCOLN,

78 LOMBARD STREET, LONDON, E.C.,

AND 36 DALE STREET, LIVERPOOL,

AGRICULTURAL AND GENERAL ENGINEERS,

And Manufacturers of Portable and Fixed Steam Engines.



Combined Threshing Machines, which dress the corn ready for market at one operation. Grinding Mills, Saw Benches, Pumps for Irrigation and Mining purposes, with all necessary gearing for being driven by steam power. Full particulars and estimates given on application to the above address.

C. S. and Co.'s PORTABLE STEAM ENGINES are adapted for every purpose to which steam-power can be applied. When intended for winding, they are fitted with reversible link motion and winding gear. They are easy of removal, as may be seen by the engraving, and can be set to work immediately on arrival.

C. S. and Co. are now doing an extensive foreign and colonial business, and are prepared to send off engines and machinery of the before-mentioned kinds in a few days from the date of order. They would also call attention to the important *reduction in prices* made for the new year.

For EXPORTATION.—The above can be obtained through British Merchants, Shippers, and Colonial Agents. (23)

IMPROVED MACHINERY FOR AGRICULTURISTS.

RICHARD GARRETT & SONS,

LEISTON WORKS, SAXMUNDHAM, SUFFOLK,

(ESTABLISHED A.D. 1778),

EARNESTLY solicit the continued support of their numerous Friends, Agriculturists, Shippers, and others; the additions made to their Works during the present year, in the erection of new sets of Workshops, fitted with the best mechanical appliances for producing Machinery of the most improved construction, expeditiously and economically, justifies their soliciting increased support, while their leading reputation as Inventors and Manufacturers of FIRST CLASS Agricultural Machinery, is a sufficient guarantee that every Machine supplied from Leiston Works will prove to the entire satisfaction of the purchaser.

R. G. & S. are now manufacturing the following Machines and Implements, which they guarantee to be thoroughly efficient in every respect:—

PORTABLE AND FIXED STEAM ENGINES. } From 4 to 40 Horse Power, suited for every kind of work
SELF-PROPELLING AND TRACTION ENGINES. } to which Steam Power is applied.
STONE GRINDING MILLS.
MORTAR AND PUG MILLS.
MILLWRIGHTS' WORK of all kinds.
SAWING MACHINERY, from 4 to 20 Horse Power.
BRICK AND TILE MACHINES.

IMPROVED SETS OF FARM MACHINERY, for Large Occupations.
PORTABLE AND FIXED MACHINERY, for Thrashing and Dressing Corn.
THE PRIZE BOLTING AND OPEN-DRUM HORSE-POWER THRASHING MACHINES.
CORN DRESSING MACHINES, for Hand, Horse, Water, and Steam Power.
BARLEY AVELLING MACHINES.
CHAFF CUTTERS, for Hand, Horse, Water, and Steam Power.
PATENT TURNIP CUTTING AND PULPING MACHINES.

THE PRIZE CORN AND SEED DRILLS.
PRIZE CORN AND SEED DRILLS WITH MANURE APPARATUS.
PRIZE SEED AND MANURE DRILLS.
LIQUID, SEED, AND MANURE DROP DRILLS.
CHAMBER'S PATENT BROADCAST MANURE DISTRIBUTOR.
GARRETT'S PATENT HORSE HOE for all Crops.
PATENT REVOLVING HOES for Root Crops.
IMPROVED PLOUGHS AND REAPING MACHINES.
&c. &c. &c.

Of which full detailed particulars will be found in R. G. & SONS' ILLUSTRATED CATALOGUE, sent postage free to any address, in English, French, or German; and any of the above Machines will be shown in operation at R. G. & Sons' Farm, near the Works, on their receiving a few days' notice.

A Copy of R. G. & SONS' new COLONIAL LIST will be forwarded free to any of the Colonies, and Shippers will be supplied with those lists, with their names and addresses printed on, free of charge, by making application for the same.

ADDRESS—R. GARRETT & SONS, LEISTON WORKS, SAXMUNDHAM, SUFFOLK. (57)

IMPORTANT TO MANUFACTURERS, MILL OWNERS, &c.

GUTTA PERCHA MILL BANDS.

THE GUTTA PERCHA COMPANY beg to state that the increasing demand for the Gutta Percha Strapping for Driving-bands, Lathe-straps, &c., fully justifies the strong recommendations they have everywhere received.

Their durability and strength—permanent contractability and uniformity of substance—their non-susceptibility of injury from contact with oils, grease, acids, alkalies, or water—and the facility with which the only joint required can be made in bands of from 200 to 300 feet long—render them superior to leather for almost all working purposes, and decidedly more economical.

TESTIMONIALS.

IMPORTANT ANNUAL SAVING.

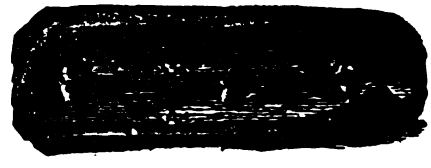
From TRUMAN, HANBURY, BUXTON, & Co., Brewery, London.

"In reply to your inquiry, we have much pleasure in bearing our testimony to the advantages, both as regards economy and saving of time, effected by the use of your Patent Gutta Percha Bands in lieu of Leather Straps. The stoppage of one portion of our works through the failing of the leather strap used to be of daily occurrence—but with this annoyance we are now never troubled. We have had these straps in operation for nearly three years, and are assured by our Engineer that *they effect a saving to us of at least* THIRTY POUNDS *a year*."

From JAMES ABERNETHY & Co., Fury Hill Foundry Aberdeen.

"We have now had Gutta Percha Bands working here *for three years*. One of them has been driving the fan blast for our smith's shop for all that time, and for anything we see, may drive it as long again. The speed of the fan is but 1,200 per minute. We have used them with complete satisfaction, driving circular saws, and in some cases where leather bands would have been quite inapplicable from damp. We have uniformly endeavoured to have the drums and pulleys so proportioned to the strain, as that there is no chance of the band slipping; and with this precaution, and taking care in using *cross bands that they do not rub*, we are quite satisfied that they are superior in every respect to leather—stronger at the same weight, and keeping quite straight in working—requiring no lacings, and very seldom any repairs."

WATER POISONED BY LEADEN PIPES.



The above engraving represents accurately a section of a leaden pipe, which was employed for a short time in conveying water from a well on the grounds of Mr. Dick, of Bonchurch, Isle of Wight.

POISONED WATER PREVENTABLE

BY THE USE OF GUTTA PERCHA TUBING.

The Gutta Percha Company have been favoured with the following letter,

From Dr. MURRAY, Hull.

"It is impossible to conceive of anything more injurious or destructive to the health of the community than the use of *leaden pipes* for the conveyance of water. The poisonous salts of lead thereby communicated are most insidious and subtle. I hail with gratitude the substitution of Gutta Percha Tubing. I have had the leaden pipe of my own house removed, and its place supplied with one of Gutta Percha Tubing. Nothing can be better. I have also recommended it to others, who have adopted the expedient."

A variety of Gutta Percha Articles, such as Mill Bands, Tubing, Sheet, Soles, Pump Buckets, Bosses, Union Joints, Bottles, Bowls, Flasks, Curtain and Cornice Rings, Solid Frames, Galvanic Batteries, &c., &c.

MANUFACTURED BY THE

Gutta Percha Company, Patentees,

GOVERNMENT SCHOOL OF MINES, Jermyn-street.—The following Courses of LECTURES are about to be commenced:—

MINERALOGY.—Forty Lectures on Mineralogy, by Warrington W. Smyth, M.A., F.R.S., to be delivered on Mondays, Tuesdays, Thursdays, and Fridays, at 3 p.m., commencing 14th February. Fee for the Course, £2.

GEOLOGY.—Thirty Lectures on Geology, by Professor Ramsay, F.R.S., to be delivered on Mondays, Tuesdays, and Wednesdays, at 2 p.m., commencing 14th February. Fee, 30s.

NATURAL HISTORY.—Fifty Lectures on Natural History, by Professor Huxley, F.R.S., to be delivered on Wednesdays, Thursdays, and Fridays, at 10 a.m., commencing 16th February. Fee, £2.

APPLIED MECHANICS.—Thirty-six Lectures on Applied Mechanics, by Professor Willis, M.A., F.R.S., to be delivered on Wednesdays, Thursdays, and Fridays, at 12 o'clock, commencing 16th February. Fee, 30s.

TRENHAM REEKS, Registrar. (127)

STEAM ENGINES FOR SALE.

PORTABLE STEAM ENGINES, from 6 to 12 horse power,
STATIONARY STEAM ENGINES, from 4 to 50 horse power,
TUBULAR BOILERS, from 4 to 50 horse power,
CORNISH BOILERS, from 4 to 50 horse power,

Are in hand, and can be despatched on eight days' notice. Prices moderate. Workmanship and Material of the best description.

Apply to R. THORNTON & Co., St. Leonard's Iron Works, Edinburgh. (60)

ENGINEERING AND MECHANICAL DRAWING CLASSES.—Instruction given in Engineering and Mechanical Drawing, comprising the preparation of plans, elevations, and sections of marine and locomotive engines, with the detail and working drawings; also the method of delineating screws, bevel wheels, &c.; orthographical projection, and tinting, shading, and colouring taught.—For prospectuses of the Day and Evening Classes apply to Mr. T. J. HILL, at the offices, 15, Old-street, City-road. (73)

EDWIN JEWITT, ENGRAVER ON WOOD AND DRAFTSMAN, 1 Pickett-place, Strand, near Temple-bar. Engineering, Scientific, and Mechanical Designs accurately engraved. Manufacturers and Tradesmen's Catalogues Illustrated. W.C. (84)

HART & SON, MALLEABLE IRON-FOUNDERS, 4 Vine-street, York-road, Lambeth. Orders for Malleable Iron Castings executed within a week. (77)

ENGINEERS' MACHINE TOOLS ready for delivery, and in progress: for Planing, Slotting, Shaping, Boring, Drilling, Screwcutting, Parallel and Cross-surface Turning; Wheel Cutting, Bolt and Nut Screwing; Nut Shaping, Washer Making, Rivet and Railway Spike Making, Boiler-plate Bending, Punching and Shearing. MACHINE TOOLS for other purposes made to order.

JOHN TODD & Co.,
Kent Iron Works, Bridge-street, Greenwich (92)

GLADSTONE & Co., CONTRACTORS and ENGINEERS.
2 John-Street, Minories, London, E.C.,

Are prepared to ESTIMATE FOR and CONSTRUCT BRIDGES, PIERS, JETTIES, &c., in Iron, Wood, or Stone. Also to supply Cranes, Girders, Turntables, and Railway Work and Plant generally. (56)

CHUBB'S LOCKS, FIREPROOF SAFES, CASH AND DEED BOXES.
Complete lists of sizes and prices may be had on application.
CHUBB AND SON,
57 ST. PAUL'S CHURCHYARD, LONDON;
28 Lord-street, Liverpool; 16 Market-place, Manchester and Wolverhampton. (4)

THE PATENT CARVING WORKS.—(JORDAN'S PATENT.)—A considerable reduction in the cost of Wood Carving is effected by the aid of the Patented Machinery, as by it the work is roughed out with great accuracy and expedition (the cutters making 7,000 revolutions per minute), while the finishing of the more minute parts is carried out by hand labour, so that the result shows precisely the same amount of artistic excellence as if it had been executed entirely by hand.

The trade supplied with Carving in the rough, or finished.
COX & SON, Belvedere-road, Lambeth. (119)

WANTED TO PURCHASE, one of CANTELO'S INCUBATING MACHINES. Must be in good working order. A new one preferred. Address, with full particulars, A. Z., Mrs. BARNETT'S, 47 Queen's Road, Brighton. (120)

BRICKS.

TO BE LET, with immediate possession, in consequence of the death of the proprietor, J. M. Paine, the DIPPENHALL SILICA FACTORY, erected for the purpose of making improved Fire Bricks, Building Bricks, Paving Tiles, &c., &c., from the Soluble Silica Rock.

Apply to view the Buildings and Bricks to G. H. Ogston, Esq., Resident Manager, Dippenhall, Farnham, Surrey; and for terms, to Messrs. Nicholls and Potter, Solicitors, Farnham. (125)

MECHANICAL, ENGINEERING, AND PATENT DRAWINGS and TRACINGS.—Drawing and Engraving on Stone. Estimates given.
W. H. BOWERS, 20 Bartlett's-buildings, Holborn. (128)

TO ENGINEERS, ARCHITECTS, PATENT AGENTS, &c.

PHOTOGRAPHS OF THE HIGHEST CLASS and of any size, taken and reproduced at a most moderate rate of charge. Reproductions of faultless accuracy, of Machinery, Models, Drawings, &c. Orders attended to in town and country. Estimates forwarded.
SPENCER, READ, & Co., 4 Agar-street, Strand. W.C. (90)

FURNACE DOORS AND BARS.—Steam increased, fuel saved, and smoke prevented, by the PATENT REGULATING AIR-DOORS. Great economy from using the "Doubly-durable" fire bars.
J. LEE STEVENS, 1 Fish-street-hill, E.C. (87)

FIRE BRICKS.—THE FARNHAM INDESTRUCTIBLE SILICIOUS FIRE BRICKS have been greatly REDUCED in PRICE, and will be delivered at the Nine Elms Station, London, at 90s. per 1,000.—Address, G. H. OGSTON, J. M., Paine's Silica Works, Farnham, Surrey. (35)

VITRIFIED BLUE BRICKS are delivered at the Nine Elms Station, London, at 80s. per 1,000.—Address, G. H. OGSTON, J. M. Paine's Silica Works, Farnham, Surrey. (36)

TO CARD CASE MAKERS.

WANTED a Good Workman in the Card Case and Pencil and Brush Case Trades, to undertake a large quantity of work of a similar character.—Apply to W. W., MECHANICS' MAGAZINE Office, 166 Fleet Street. (131)

TO ENGINEERS, INVENTORS, AND OTHERS.

WANTED, occasional employment by an expeditious Mechanical Draughtman, who has had considerable experience in assisting inventors in carrying out their plans, and afterwards introducing them to the notice of those willing to take them up. Or the Advertiser would not object to take the charge of a small machine shop or railway work.—Apply to J. J., 171 Strand. (99)

ENGINEERS' TOOLS.

FOR SALE, a Self-acting Slide LATHE, 11-inch Centres, and Bed 12 feet long, complete; and TWO PORTABLE PUNCHING and CUTTING MACHINES, one suitable for ½-inch plates, and the other for ¾-inch plates, both adapted for steam or hand power.

Apply to Messrs. PAGE & CAMERON, Auctioneers and Valuers, 64 Old Broad Street, E.C. (117)

STEAM ENGINES.

FOR SALE, a superior HIGH PRESSURE HORIZONTAL STEAM ENGINE of 6-horse power, 8-inch cylinder, and 1-foot 6-inch stroke. One of 8-horse power, 10-inch cylinder, and 1-foot 6-inch stroke. One of 10-horse power, 12-inch cylinder, and 2-feet stroke. Two of 14-horse power, 14-inch cylinders, and 2-feet stroke; and one of 30-horse power, 20-inch cylinder, and 3-feet stroke.

Apply to Messrs. PAGE and CAMERON, 64 Old Broad Street, E. C., London. (124)

ENGINEERING BUSINESS FOR SALE.

OWING to the continued ill health of the Proprietor, the first-class business of an Engineer and Crane and Block Maker is offered for sale. It has been established in the Metropolis for nearly 30 years, and has enjoyed extensive patronage amongst Brewers, Manufacturers, Warehousemen, and others, in and about London; the business done amounting to nearly £8,000 per annum. About £3,200 would be required, (part of which, however, may remain for any reasonable time on good security,) which is the bare value of the tools, patterns, and stock in trade. The premises, including good dwelling-house, very conveniently situated, and capable of accommodating from 60 to 70 hands, are held upon a long lease, at an extraordinary low rental, not exceeding £100 per annum, taxes included. Many of the tools are nearly new, and of the best construction. The present proprietor, who relinquishes the business solely on account of ill health, would give every assistance in his power to those succeeding him; and as his foreman, who has been with him for nearly ten years, is thoroughly acquainted with the practical parts of the business, any gentleman desirous of commencing as a manufacturing engineer would find the present a very favourable opportunity. As all accounts have been, for many years past, collected quarterly, a very small amount, say £800, would suffice as working capital. Full particulars may be obtained by application to E. E. ALLEN, Esq., MECHANICS' MAGAZINE Office, 166 Fleet Street, E.C. (130)

WROUGHT IRON BRIDGES.

This day, with numerous detail Plates, 8vo, cloth, Price 15s.

THE CONSTRUCTION OF WROUGHT IRON BRIDGES: By JOHN HERBERT LATHAM, M.A., Civil Engineer.

From the "Athenæum."

"The great merit of Mr. Latham's book is that it deals with practice more than theory. All the calculations in his book connected with the strength of girders are based upon their actual application and working. . . The present publication, which abounds in practical investigations into girderwork in all its bearings, will be welcomed as one of the most valuable contributions yet made to this important branch of engineering."

Cambridge: MACMILLAN & Co.; and 23 Henrietta-street, Covent-garden, London. (122)

TO ENGINEERS' TOOL MAKERS, AND OTHERS.

THE ADVERTISER is desirous of meeting with an engagement as TOWN or DISTRICT AGENT for an Engineers' Tool Maker, or firm whose business lies amongst Engineers and practical men. He is an Engineer by profession, has for many years been engaged in bringing into operation several inventions, and can give unexceptionable references. A very moderate fixed salary only expected. Address M. C., MECHANICS' MAGAZINE Office, 166 Fleet-street. (78

TO STEAM SHIP OWNERS, ENGINEERS, AND OTHERS.

How's Patent Steam Engine Counters, can be read at sight.

These Counters register the number of revolutions made by an engine or other mechanism. They may be used for ascertaining the duty of Pumping Engines and Water-wheels; the revolutions on board a steam-vessel; to calculate the slip of the propeller; and in a locomotive to test the slip of the wheels.

How's Patent Salinometer, for Steam Boilers using Salt Water.

By these, the density of the water in the Boiler is at all times accurately shown, and a saving of boiler and fuel is effected. They are adopted by the Admiralty, the Honorable Trinity Corporation, and others. Copies of Testimonials from Messrs. Penn, Messrs. Maudslay, and others, will be forwarded on application.

How's Engine-Room Telegraph, for communicating between Captain and Engineer. Society of Arts Prize Medal, 1855.

This is a Mechanical Telegraph, and by its peculiar construction, error or misunderstanding is rendered impossible. It is now extensively adopted, and gives great satisfaction.

How's Patent Fresh Water Apparatus for Ships' Use.

This apparatus is designed for the distillation of Fresh from Salt Water; and on long voyages, and where the supply of water is scanty, it will be found invaluable. Testimonials may be seen.

Patent Steam Pump and Fire-Engine for Ships' Use.

This Steam-pump occupies but a small space; works perfectly noiselessly, and throws an immense volume of water. An Illustrated Circular of Fresh Water Apparatus and Steam-pump combined, free on application.

How's Patent Machine for Cutting Bolts, Rods, Spindles, Wire, &c.

Simple in construction, inexpensive, occupies but little space, and will not easily get out of order.

A Pamphlet Illustrative of the above, sent free by post, on application to

A. P. HOW, ENGINEER,

81 MARK LANE, LONDON.

EVERY DESCRIPTION OF ENGINEERS' TOOLS, ENGINE ROOM STORES, &c., &c., SUPPLIED.

(89)

SCOTT'S
PATENT GRASS SEED SEPARATOR,

which entirely extracts the Seeds of "COUCH," "TWITCH," "SPEAR," or "HAIR" GRASS, and other impurities from

PERENNIAL AND ITALIAN RYE-GRASS, &c.,

AND

SCOTT'S PATENT CARROT SEED BEARDING

AND

CLOVER AND TREFOIL MILLING OR DRAWING MACHINE,

which effectually removes the beard from Carrot Seed, rendering it fit for sowing with facility by drill or otherwise, and by the separation of abortive or diseased grains vastly increases its vegetative per centage. By a slight modification it is applicable to the other purposes before mentioned.

These Machines were admittedly the most novel, and, at the same time, the most useful and important to the Farmer of any exhibited at the late SMITHFIELD CLUB SHOW.

They may be seen at work at the Establishment of the Manufacturer,

Mr. T. MIDDLETON, Engineer, Southwark.

Communications to be sent to the Patentee, J. SCOTT, 111 Drummond Street, Euston Square, London, N.W. (48.)

THE ROYAL AGRICULTURAL SOCIETY OF ENGLAND'S
FIRST PRIZE REAPER.

BURGESS & KEY, PATENTEES AND SOLE MAKERS, 95 NEWGATE STREET, LONDON.

MANUFACTORY, BRENTWOOD, ESSEX.

BURGESS & KEY'S extensive Manufactory is wholly occupied in the Manufacture of

REAPING MACHINES AND GRASS MOWING MACHINES,

upon which they have concentrated their efforts since the year 1851. Their practical experience enables them to produce Reaping Machine which can be depended on by the Farmer.

Owing to the excessive demand for last season, many orders were left unexecuted. BURGESS & KEY therefore earnestly request that orders for next season (1859) be sent as soon as possible, otherwise they cannot guarantee to deliver in time.

Price £42 10s. Net Cash, at the Works, complete with Conical Screw Divider for long Grain; without the Conical Screw, £40. Extra Knife, £1 5s. If other extras are supplied they are charged for. A man sent to start the Machine, if required, on payment of his expenses.

BURGESS AND KEY'S GRASS-MOWING MACHINE
(ALLEN'S AMERICAN PATENT).

Before introducing this Machine to the English public, BURGESS & KEY determined to fully test its capabilities, and the all-important point—durability. One Machine cut, on the farm of Mr. C. Hall, Havering, Romford, Essex, 83 acres Grass; and the same Machine afterwards cut, on the farm of Mr. Tabrum, Bovis Hall, near Brentwood, Essex, 100 acres Grass, and 20 acres Clover. The work done was declared to be better and lower than the scythe, and at the rate of 1 acre per hour. Orders have been received from both those Gentlemen, and numerous others, for Machines for next season. Price £30.

BURGESS & KEY'S Manufactory is entirely devoted to REAPING MACHINES and MOWING MACHINES.

95 NEWGATE STREET, LONDON.—MANUFACTORY, BRENTWOOD, ESSEX.

FURTHER PARTICULARS AND CATALOGUES SENT ON APPLICATION. (89)

By Her Majesty's Royal Letters Patent.

(118)

RANSOME'S PATENT IMPERISHABLE SILICIOUS STONE.—Chimneypieces, Balustrades, Capitals, Trusses, Terminals, Fountains, and Vases; also, Enamelled Stone Chimneypieces, of great beauty and novelty, at reduced prices. Monumental or Mural Memorials, Grave Stones, Space Markers, and Indicators for Cemeteries, &c., of every description, at the lowest price.

RANSOME'S PATENTED PROCESS FOR PRESERVING STONE.—Invaluable in its application to Public Edifices and Private Residences. By this process the softest and most friable stone can be rendered impervious and imperishable, and decay at once arrested and prevented.

RANSOME'S PATENT STONE FILTERS FILTERING SLABS.—Manufactured for every Private or Domestic purpose, for Manufactories, Public Companies, Shipping, &c. Several hundred thousand gallons of water are filtered daily by Ransome's Patent Stone Filtering Slabs, for the town of Southampton. They have also been adopted by the Admiralty, the Board of Ordnance, the Colonial Land and Emigration Commissioners, and other Public Bodies for several years; also in the City of Rotterdam, with the most perfect success.

For particulars, specimens, illustrations, and agencies, apply to

Mr. FREDERICK RANSOME,

WHITEHALL WHARF, CANNON ROW, WESTMINSTER;

OR PATENT STONE WORKS, IPSWICH.

A liberal discount allowed to the Trade or to Shippers.

(14.)

A NEW DISCOVERY IN WASHING HOUSEHOLD LINEN.

NO FAMILY SHOULD BE WITHOUT HANCOCK'S UNIVERSAL WASHING MACHINE. It effectually cleanses the Crevices of Baby-linen, Collars, Wristbands, &c., without the possibility of injuring the Linen or Collars. Received 500 Testimonials.

PRICES.

No. 2 Washes 9 Shirts in from 3 to 10 minutes; or 4 Sheets in 5 minutes	£5 5 0
No. 3 Washes 12 Shirts in from 3 to 10 minutes; or 6 Sheets in 5 minutes	7 11 0
No. 4 Washes 18 Shirts in from 3 to 10 minutes; or 12 Sheets in 5 minutes	12 12 0

And all other Articles in proportion.

J. L. HANCOCK, Sole Manufacturer and Patentee, 62 Pentonville-road, London. (89)

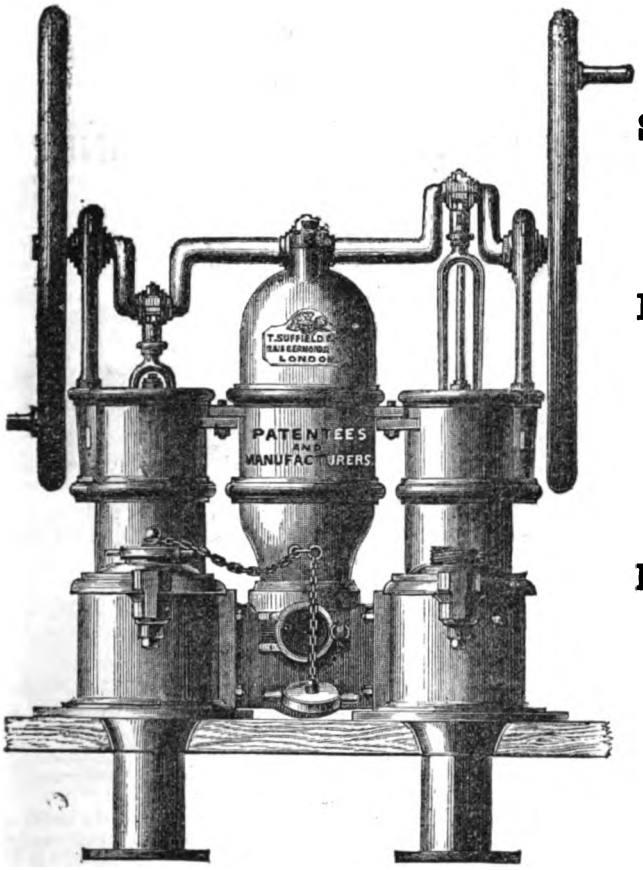
T. SUFFIELD AND CO.

Call the particular attention of

SHIP-OWNERS. SHIP-BUILDERS, AND COMMANDERS OF STEAM AND SAILING VESSELS,

to the Simple and Efficient Arrangements of their

PATENT PUMPS.



Ships' Pumps

AND

Fire Engines,

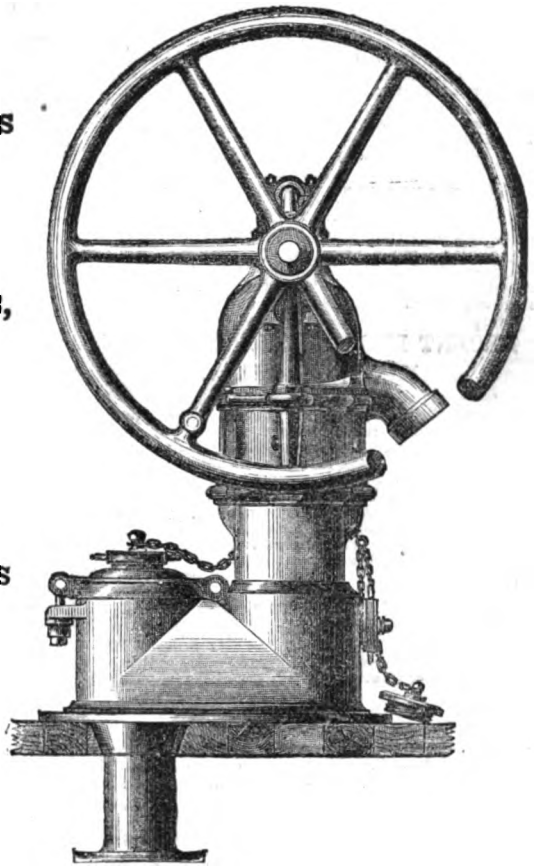
Fixed and Portable.

WITH

Patent Valves

AND OTHER

Improvements.



These Pumps are free from that liability to choke which is common to other Pumps, and their Working Parts are not susceptible of derangement either from wear or from being long out of use. They pass entirely through them, with ease, any substance that may enter the Suction Pipes. The Novelties in these Pumps are their adaptation to the varied duties of Ships' Pumps; the facilities they afford for Cleansing the Suction Pipes, and for Sounding or Examining the Valves; the readiness with which they may be used for Ventilating the Bilge, or for acting as a Syphon either for Watering the Ship, or for extinguishing Accidental Fires on board; the rapidity with which they can be converted into Fire Pumps, or be applied to the Washing of Decks; and their capability of Pumping from Several Compartments.

T. SUFFIELD AND CO.

Also respectfully solicit the attention of STEAM SHIP BUILDERS and OWNERS to their Large and Varied STOCK of

ASSORTED STORES FOR MARINE PURPOSES.

They keep a Large Stock of Goods, of their own Manufacture and from the Best Makers, constantly on view; so that by a visit to their Works or Depôt, much valuable time may be saved by Managers, Engineers, and other Gentlemen who may require such Stores, together with a further saving in the cost of such Articles.

DEPOT, 116 FENCHURCH STREET, E.,

(OPPOSITE MARK LANE.)

This Day,

THE PATHFINDER: a Weekly Journal of Political, Social, and Religious Reform. Conducted by P. W. PERFITT. Published by JAMES PATTIE, 31 Paternoster-row, and by G. GLAISHER, 470 Oxford-street. (96)

WORKS PUBLISHED BY BLACKIE AND SONS.

RAILWAY LOCOMOTIVES.

THEIR PROGRESS, MECHANICAL CONSTRUCTION, and PERFORMANCE, with the recent Practice in England and America. Illustrated by an extensive Series of Plates, and numerous Engravings on Wood. By DANIEL KINNEAR CLARK, C.E. To be completed in about 22 parts, imperial 4to, 2s. 6d. each.

This work will combine the Locomotive Section of the Author's Treatise on Railway Machinery, with extensive additions illustrating the practice of English Locomotive Engineers of the present day, and presenting the most recent attainments in American practice. It will also include the consideration of a variety of questions bearing upon the improvement and economical working of the Locomotive.

Parts 1 *to* 12 *now ready.*

RAILWAY MACHINERY.

A Treatise on the Mechanical Engineering of Railways; embracing the Principles and Construction of Rolling and Fixed Plant, in all departments. Illustrated by a Series of Plates on a large scale, and by numerous Engravings on Wood. By DANIEL KINNEAR CLARK, C.E. 2 vols., half morocco, £4 15s.

RECENT PRACTICE IN THE LOCOMOTIVE ENGINE.

Being a Supplement to "Railway Machinery." Comprising the most recent Improvements in English Practice, and Illustrations of the Locomotive Practice of the United States of America. By DANIEL KINNEAR CLARK, C.E. To be completed in Eight Parts, imperial 4to, 2s. 6d. each.

This work will consist simply of the new portion of Railway Locomotives announced above. It is published separately for the benefit of those who already possess the Author's Work on Railway Machinery.

Parts 1 *to* 4 *now ready.*

BLACKIE & SON, Warwick-square, City, London; and all Booksellers. (126)

Price 6d. Post free for Six Stamps,

SCREW PROPULSION: a Description, with Drawings of GRIFFITH'S PATENT SCREW PROPELLER, with all its recent improvements, showing its advantages over all others. With Directions for its application and use.

"Well worthy of perusal."—MECHANICS' MAGAZINE.

London: MATTHEW SOUL, 3 Leadenhall-street. (129)

Price 10s. 6d., handsomely bound, gilt edges.

THE UNIVERSAL ATLAS; containing 400 Coloured Maps, Diagrams, and Illustrations of Astronomy, Physical Geography, Geology, the Vegetable Kingdom, &c., with popular description. A most interesting and instructive, as well as elegant, work for a present.

London: JAMES REYNOLDS, 174 Strand. (41)

TO MARINE ENGINEERS, OR SHIP-BUILDERS.

THE PROPRIETOR of a VALUABLE PATENT for Double-expansive Marine Engines (by which great economy of space and fuel is obtained) is desirous of entering into arrangements with a respectable firm for the construction of the same. An adequate portion of the patent-right would be assigned by the advertiser to any firm taking the matter up; and he would render all assistance in his power, either in London or elsewhere, amongst ship-owners (to many of whom he is well known), in obtaining contracts, &c. Unexceptionable references given. Address C. E., MECHANICS' MAGAZINE Office, 166, Fleet-street. (76)

HALKETT'S GUIDEWAY STEAM AGRICULTURE will be Exhibited at Canning-place, Kensington Toll Gate, South of Kensington Gardens, on Wednesdays, the 9th, 16th, and 23rd of February, and to private view upon previous appointment. By this system, every operation of the Farm is performed by Steam Power, the land largely increased in value, and the cost of cultivation greatly reduced. A paper read before the Society of Arts, illustrations, &c., will be forwarded upon application to the Office, 80 Chancery-lane, W.C. (104)

SCHOOL FOR MECHANICAL ENGINEERING and SCIENTIFIC EDUCATION, at the College, Chester.

In Addition to English and Mathematics, all the Pupils are taught Drawing suitable for the Architect or Engineer, and in the Laboratory the Principles as well as the Practice of Chemistry.

The use of Tools, the Construction of Machinery, and the Principles of Mechanism may be studied in the various Workshops of the School.

French and German are taught to all who desire it without any extra charge.

Chemical Analyses undertaken, Steam Engines and Machinery examined and reported upon, and Mechanism designed for special purposes. For further particulars apply to the Rev. ARTHUR RIGG, Chester. (95)

PIERCE'S

UNRIVALLED

PYRO-PNEUMATIC FIRE-LUMP WARMING AND VENTILATING STOVE GRATES,

WITH the cheerful, open fire, producing healthful warmth, with continuous Self-acting Ventilation, for Churches, Schools, Public Buildings, Banking Houses, &c. These Grates are manufactured solely by PIERCE, the Inventor, for which he received the Prize Medals of London in 1851, and of Paris in 1855.

PRICE, from £7 10s.

ILLUSTRATED CATALOGUE, with Prices and Estimates for Work, furnished on application to the Inventor and Sole Manufacturer.

Also his

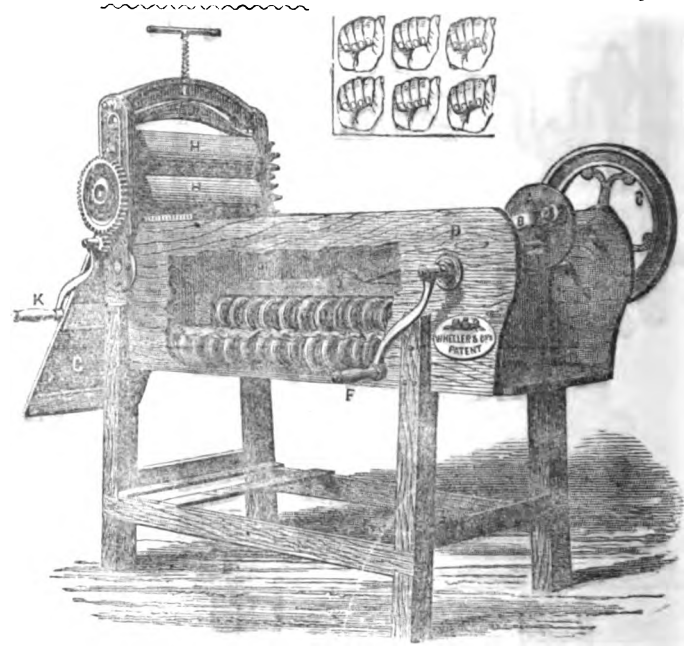
IMPROVED COTTAGER'S GRATE,

For Warming Two Rooms with only One Fire. Prices, 30s. and 35s.

PIERCE, No. 5 JERMYN STREET, REGENT STREET. (111)

T. WHEELER AND CO.'S

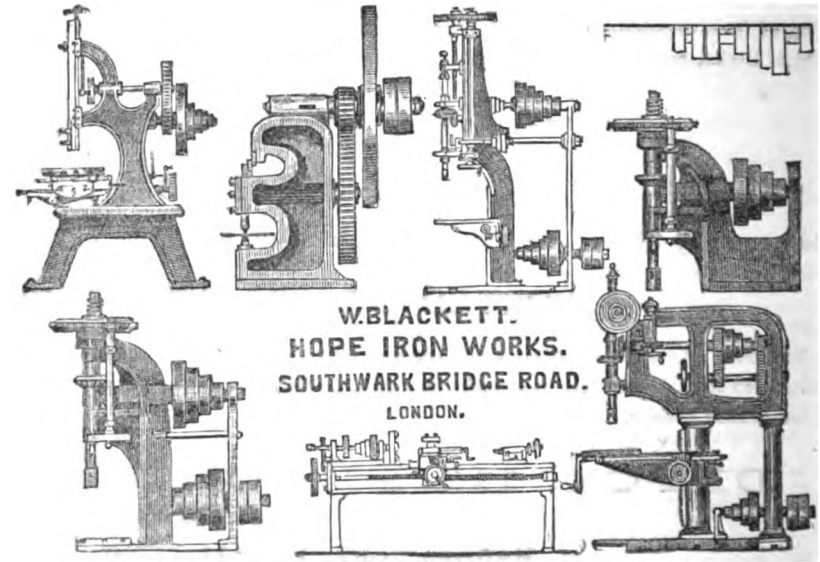
"O XONIAN KNUCKLE WASHING MACHINE."



THE Improvements in these New Inventions are the non-exposure of the user's hands to the dangerous parts of the Machine, and the rapidity with which the work is done. These Machines have neither bands or wheels passing on the outside, wherein lies the liability to accident. The rubbers are the truest representation of the knuckles or hand washing yet brought out; the compensating floating rubbers work at right angles, backward and forward, in the same manner as does the hands. These Machines can be supplied with rubbers that represent a person's hand in the action of rubbing; the knuckles, finger nails, and palm of the hand being truly modelled. They are capable of Washing Clothes of every description whatsoever, the largest bedding to the most delicate piece of muslin can be washed without breaking a single thread; in fact, such is the delicacy of the action of these Machines, that the paper you are now reading can be passed between the rubbers without sustaining any injury, at the same time being thoroughly effective in cleansing. The Patentees confidently recommend these Machines to the notice of Laundresses, Heads of Families, Hotels, Emigrants, &c. So simple is the action of this Machine, that a boy or girl of 10 or 12 years of age can work it; the only skill required is to soak the clothes one hour before placing them in the Machine, placing a portion of the clothes at the handle end of the Machine; laying on the rubbers a part of them; turn the handle, and the clothes will pass through between the rubbers to the opposite end, effecting a saving of at least 50 per cent.

Prices: Washing Machines, £1 6s., £2 6s., £3 6s., £4 10s., £5 15s.; Washing, Wringing, and Mangling, £8 £10 15s., £14 14s.—Full Instructions sent with every Machine. Testimonials or References sent on application.

MANUFACTORY, ALBION WORKS, PARK END STREET, OXFORD (114)



W. BLACKETT has in Stock a variety of Vertical and Horizontal Steam Engines, Boilers, and Engineers' Tools, ready for delivery on the shortest notice. Apply as above. (70)

LIST OF MISCELLANEOUS TENDERS INVITED, AND ENGAGEMENTS OPEN.

RAILS, *North Eastern Railway.*—The directors will receive tenders for 1,000 tons of iron rails, 82lbs. to the yard; and also for 1,000 tons of 66lbs. to the yard. Forms, &c., on application to Mr. J. Bourne, engineer,, Central Station, Newcastle. Tenders to the Secretary by Thursday the 17th inst.

GUARANTEED RAILS, *North Eastern Railway.*—The directors will also receive tenders for 2,000 tons of iron rails, 82lbs to the yard, to be guaranteed for seven years. Tenders for the whole or a portion. Forms, &c., on application to the Secretary, at York. Tenders to the Secretary by Thursday the 17th inst.

RAILWAY, *Exeter and Exmouth.*—For the construction of railway from Topsham to Exmouth (about 5 miles). Plans, &c., at office of engineer, Mr. Errington, 13 Dukestreet, Westminster, London. Tenders to 10th inst.

RAILWAY CHAIRS, &c., *Lancaster.*—The directors of Lancaster and Carlisle Railway will receive tenders for about 350 tons of wrought-iron bracket chairs, and about 30 tons of wrought-iron bolts, nuts, &c. Patterns at the Castle Station, Lancaster. Tenders by the 15th inst. to the Secretary, Lancaster.

RAILWAY BUILDINGS, *Scotland.*—For erection of iron store, office buildings, &c., at Cowlairs, and house for station master, at Linlithgow, on Edinburgh and Glasgow Railway. Plans, &c., at office of Mr. Adie, engineer. Plans with Secretary on 8th inst.

BUILDINGS FOR AN AGRICULTRAL SHOW, *Ireland.*—The Dundalk Local Committee of the Royal Agricultural Improvement Society of Ireland require tenders—First, for erecting, on the site of the proposed show-yard at Dundalk, County Louth, 2,000 feet of temporary timber shedding, in such lengths as may be agreed upon, and 16 ft. wide, to be made as waterproof as possible; the contractor to remove them after the show without any extra charge. Rate per foot? Second, for supplying all the internal shed fittings (and removing same after the show) for cattle, horses, sheep, and swine. The cost of each department to be separately stated. Third, for erecting a boundary wall of timber, about 1,400 ft. long, 8 ft. high, overground, and removing same after show. Rate per 100 feet? Fourth, for supplying water at different places upon the ground, and pumping the supply of same into a tank for such time as may be required before and during the show. The contractor to furnish a plan for this item along with his tender. All the foregoing will require to be completed on the 8th of July next, under a heavy penalty. Every information connected with the timber requisites, and the plans for same, to be obtained on application at the Royal Agricultural Improvement Society's offices, Dublin, or at the office of the Secretary of the Local Committee, County Court House, Dundalk, with whom tenders must be lodged on or before the 12th inst.

LIGHTHOUSES, *Scotland.*—For execution of repairs on roofs of towers at Sander Lighthouse, Island of Sander, Clyde; according to plans, &c., by Messrs. D. & T. Stevenson, engineers. Plans, &c., in hands of J. Beith, jun., Esq., Provost of Campbelton. Tenders to Secretary of Commissioners of Northern Lighthouses, at his office in Edinburgh, by 21st inst.

SEWERS, *London.*—For laying Sewers in Poplar district as follows:—East-ferry-road, 420 feet, 3 feet 9 inches by 2 feet 6 inches—one brick; West-ferry-road, 222 feet, 3 feet 9 inches by 2 feet 6 inches—one brick; Church-path and Castor-street, 570 feet of 12 inch patent pipe, with requisite gullies, flushing boxes, manholes, &c. Plans, &c., at office of District Board of Works, East India Dock-road, until the 7th. Tenders to 8th.

SEWERS, *London.*—For construction of pipe sewers in Limehouse district for Board of Works, viz.: in Manning-street, North-street, Eastfield-street, Catherine-street, Catherine-place, Burn-street, John-street, Henry-street, Parnham-street, Edward-street, George-street, Samuel-street, James's-street, Rossetta-street, Williamstreet, and Anchor-street, in the parish of Limehouse, with other works, and for maintenance of works in repair for 12 months. Plans, &c., with form of tender, at office of the Board, White Horse-street, Commercial-road-east. Tenders at same place to 3 p.m., 8th inst. Tenders accompanied by £20 bank note.

NEW ROADS, *Burntwood.*—For forming and gravelling nine miles of new roads over Burntwood Common. Plans, &c., at Star Inn, Burntwood, near Lichfield, further information of Messrs. W. Fowler and Son, surveyors, Waterloo-street, Birmingham, to whom tenders must be sent before 21st Feb.

ROADS AND INCLOSURES, *Somersetshire.*—For construction of three miles 10 chains of roads, and erection of seven miles 50 chains of fences. Plans at house of Mr. J. Litson, Lynton. Tenders to 4th inst.

ROAD, &c., *Surbiton.*—The Surbiton Improvement Commissioners require tenders for from 100 to 200 yards of road and footpaths in Britannia-road, Surbiton-hill. Specifications, &c., at their offices, Victoria-road, Surbiton, or at offices of Mr. J. Bell, 21 Abchurch-lane, London. Tenders to 12th inst.

SEA-BATHING INFIRMARY, *Scarborough.*—For new infirmary at Scarborough. Plans, &c., at office of Mr. W. B. Stewart, architect, 10 Aberdeen-walk, Scarborough. Quantities for 5s. in stamps. Tenders by 8th inst. to Mr. R. Huie, jun., 38 Queen-street, Scarborough.

WAREHOUSE AND DWELLING-HOUSE, *Altrincham.*—For the erection of a warehouse and dwelling-house at Altrincham, for Messrs. Gaskarth. Plans at offices of Mr. M. Roscoe, architect, Bowdon.

FARMHOUSE, *Derbyshire.*—For erection of a farmhouse at Aldercar, near Alfreton, Derbyshire. Drawings, &c., at Butterley Ironworks, Ripley, and of the architect, Mr. C. H. Edwards, 4 St. James's-terrace, Camden Town. Tenders to Feb. 22.

HOUSES, *Dublin.*—For building five first-class houses in Fitzwilliam-place, Dublin. Plans, &c., with Mr. J. Maguire, architect, Kenilworth-square, South Ruthgar. Tenders to 8th Feb.

HOUSES, *Nottingham.*—For erection of four dwelling-houses and shops. Particulars at offices of Mr. F. Bakewell, architect, Thurland-street, Nottingham. No date.

Aberdeenshire.—For masons' and carpenters' works at Mayen, Bothiemay. Plans, &c., with Mr. Bonnyman, Mayen, until 19th inst., on which day materials and sites will be pointed out. Tenders to 23rd inst.

MANSE, *Scotland.*—For masons', carpenters', slaters', and plasterers' work of a manse and offices, to be built at Airdallie. Plans, &c., with Mr. Clark, Strichen. Tenders to 17th inst.

PAVING, *Rugby.*—For providing materials and paving footpaths in two streets at Rugby. Plans, &c., at office of surveyor to local board of health. Tenders to the 10th inst.

SAVINGS' BANK, *Bridgnorth.*—For alterations to the Savings' Bank, Bridgnorth, Salop. Plans, &c., at office of Mr. R. Griffiths, architect, 66 High-street, Bridgnorth. Tenders to 14th inst., to A. S. Trevor, Esq., The Vinery, Bridgnorth.

ALMSHOUSES, *London.*—For erection of New St. Pancras Almshouses. Competition limited to ratepayers. Quantities, &c., at office of the architect, Mr. H. Baker, 11 Upper Gower-street. No date.

PARSONAGE, *Ross.*—For a Parsonage-house at Hentland, near Ross, Herefordshire. Plans, &c., at the offices of Mr. Apperley, St. John-street, Hereford. Tenders to 15th Feb., to Rev. W. Poole, Hentland.

LIFT AND FORCE PUMP, *Sunderland.*—The Guardians of Sunderland Union will receive tenders (with a plan) for a lift and force pump. Tenders to Mr. N. C. Reed, clerk to guardians, by 7th Feb. Further information from Mr. Anthony Wardropper, builder, Coronation-street, Bishopwearmouth.

COAL, *The Navy.*—For supplying at Her Majesty's Naval Yard, at Trincomalee, 3,000 tons of South Wales coals. Conditions at the office, Somerset Place. Tenders to two o'clock 15th inst., address to Secretary of Admiralty, with a letter signed by two persons, engaging to become bound with the person tending in sum of £1,500 for performance of contract.

PIT SINKING, *Newcastle-on-Tyne.*—The Weardale Iron Company will receive tenders for sinking of two pits at Bishop's Close, Whitworth. Specifications, &c., at Tudhoe Iron Works; or Mr. W. Burrell, Black Prince Colliery, Tow Law. Tenders by the 23rd February.

TIMBER, *Ireland.*—For the supply at Dublin or Belfast of a large quantity of red pine or memel flooring, sawn out of St. John's battens, with two deep cuts in each, state price per square, delivered free at any railway station in Dublin or Belfast. Tenders to F. K., Timber, *General Advertiser Office*, Dublin. No date.

WATER SUPPLY PLANS, *Denbigh.*—A premium of £20 will be paid for plan for supplying the town of Denbigh, North Wales, with water, with an estimate of the expense. The population is 4,000. Information on application to Mr. R. Williams, Town Clerk, Denbigh. The plans and estimates to him by 1st March.

DESIGNS WANTED, *Birmingham.*—Twenty Guineas premium will be given for the best design for washing apparatus, machinery, and furnaces, applicable to lead ash smelting. The furnace to consume smoke. For information, apply by letter to Messrs. Herbert Mills and Co., lead merchants, 28 Bennett's Hill, Birmingham. Designs to them by 1st March.

ROAD SURVEYOR, *Scotland.*—The Turnpike and Statute Labour Road Trustees of Cupar, county Fife, will have a vacancy for a road surveyor, on the retirement, on the 6th of April, of Mr. Alexander, the present surveyor. Applications by March 1st, to the clerk of the trustees, Cupar, Fife, stating terms and containing certificates.

MANAGING ENGINEER, *Scotland.*—A manager to take charge of an extensive engineering establishment in town; thorough acquaintance with engineering necessary. Applications, with references, to No. 74, *North British Advertiser* office, Glasgow.

SURVEYOR, *Portsmouth.*—A resident surveyor for Portsmouth, under commissioners for paving, lighting, &c. Salary £60 a-year and residence at commissioners' office, or £20 in addition if he provide his own residence, and appropriate therein an office for commissioners. Printed particulars from the clerk, to whom testimonials must be sent by 14th inst., when at 7 in the morning the election will be made, and condidates must attend.

MECHANICAL DRAUGHTSMAN, *Manchester.*—A first-class draughtsman, accustomed to locomotive engine work. A liberal salary and permanent employment to a suitable person. R 22, *Guardian* office, Manchester.

PRACTICAL MECHANIC, *Hull.*—Messrs. Martin Samuelson and Co., Engineers and Iron Shipbuilders, Scott-street, Hull, want a practical mechanic to take the charge and general superintendence of engine and boiler works. He must be a good draughtsman, thoroughly acquainted with marine engineering and general machinery, and competent to make up estimates. Applicants to state salary expected.

LAND AND MINE SURVEYORS, *Manchester.*—A mining engineer, in Lancashire, is in want of an assistant competent to make surface and underground surveys, take sections of mines, make out measurements, and to make neat and correct plans, &c., &c. State age, references, and salary required. Apply to P 93, *Guardian* Office, Manchester.

ENGINEER AND MILLWRIGHT, *Kendal.*—In an engineer and millwright's establishment, a gentleman, to take active part in management. Competent to prepare working drawings and estimates for mill gearing, corn mills, water wheels, cranes, &c. Parties having extensive experience in general millwright's work only need apply. Address (by letter only), with particulars of former employment, and references, to C. G. Thompson, Esq., solicitor, Kendal.

MILL AND FORGE MANAGER, *South Staffordshire.*—A mill and forge manager for iron works in South Staffordshire. Good references required. Address by letter, N 28, *Journal* Office, Birmingham.

TO ENGINEERS, MILLWRIGHTS, MACHINISTS, &c.

VULCANIZED INDIA-RUBBER

In any of the following forms, of any size, or to Working Drawings for all MECHANICAL *purposes:—*

WASHERS for Steam and Gas Joints.
VALVES for Marine and other Steam Engines.
ENGINE-PACKING (Elastic).
PUMP-BUCKETS ,,
HOSE-PIPES.
GAS-TUBING.
SUCTION HOSE.
FIRE ENGINE AND FACTORY HOSE.
WATERPROOF CART, VAN, AND WAGGON COVERS.
MACHINE AND MILL-BANDS fo Driving all kinds of Machinery.
RAILWAY BUFFER SPRINGS.
BALL VALVES.
PUMP-PACKING (Rings or Rope).
WHEEL-TIRES (Noiseless).

N.B.—A Large Stock of the above always on hand, and any modification made to order.

Please address all communications to the Manufactory,

JAMES LYNE HANCOCK, VULCANIZED INDIA-RUBBER WORKS,
Goswell Road, London, E.C. (85)

HOBBS'S LOCKS.

The attention of Architects and Builders is respectfully invited to
HOBBS'S NEW MORTISE LOCKS,

Which are now manufactured by PATENT STEAM MACHINERY, and, while superior to any other locks in the market, are sold at a price which defies competition. The Plates are made of number "Twelve Gauge" Iron, and being so thick, the pins cannot be loosened by the constant jarring of the door. The security consists in four double-acting levers, while, to secure unusual freedom of motion and prevent the wear of the parts,

HOBBS'S PATENT FRICTIONLESS FOLLOWER

Is also applied. The retail price of these Locks is 10s., from which a liberal discount is allowed to the trade.

HOBBS'S NEW MORTISE LOCKING LATCHES FOR STREET DOORS,
Price 18s. And
HOBBS'S NIGHT LATCHES, RIM OR FLUSH, PRICE 10s.,

Are also recommended, together with every description of Lock required for house and cabinet work. Lists of Prices will be forwarded on application, post free.

N.B.—A complete Assortment of FIRE and BURGLAR-PROOF SAFES (Milner's Patent), fitted with HOBBS'S PATENT PROTECTOR LOCK, POWDER-PROOF.

ALSO, STRONG-ROOM DOORS, CASH AND DEED BOXES, ETC.

Address—Hobbs, Ashley, and Co., 76 Cheapside, E.C.
MANUFACTORY, ARLINGTON STREET, NEW NORTH ROAD. (86)

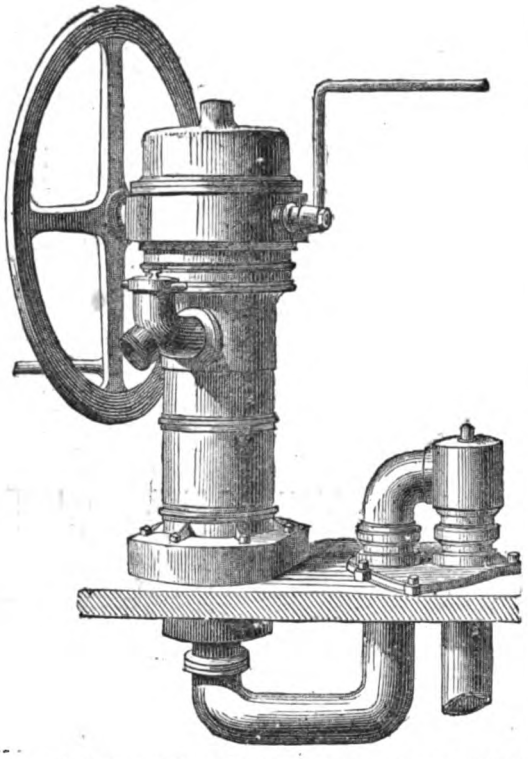
Under the Patronage of the Board of Admiralty.

SHIPS' PUMPS OF HER MAJESTY'S NAVY.

JOSIAH STONE,

Sole Manufacturer of DOWNTON'S well-known and much approved SHIPS' PUMPS, which have been used in preference to all others on board the vessels of Her Majesty's Navy, for upwards of thirty years, and have given the greatest satisfaction, effectually answering all the purposes required of any Ships' Pumps, and capable of throwing most powerful jets of water in case of fire.

These Pumps have also been most extensively used on board merchant vessels, both at home and abroad, and have been supplied to the Royal Navies of France, Prussia, Holland, Russia, Spain, and Turkey. The Pumps are portable, as they may be easily removed from the ship and put to work in a boat alongside in a few minutes. Each pump is fitted with a large foot valve plate (which may be placed in any part of the vessel most convenient), and from which communication is made to any number of distinct compartments in the vessel. In case of any of these pipes fouling, the water, by an almost momentary attachment, may be forced from the Pump downwards, so as to clear all obstructions, preventing any possibility of stoppage. The valves are of the simplest description, and being faced with ordinary leather discs, the latter may be renewed in a few minutes by the most inexperienced hands. By the peculiar construction of these Pumps, a most perfect and uninterrupted flow of water may be maintained; so uniform as to be undistinguishable from that proceeding from a cistern. The Pumps are made of several sizes, those of 7, 9, and 12 inches bore being most generally used. They may, however, be ordered of any dimensions required, and may be fitted either with one or two fly wheels. A standard, &c., is also supplied with these Pumps, to enable them, when necessary, to be used as ordinary hand-lever pumps.



JOSIAH STONE, Engineer, Manufacturer of all descriptions of PUMPS and FIRE ENGINES for Land and Ships' Use; Brass and Iron Founder and Finisher, Nail and Rivet Maker, &c.

CONTRACTORS FOR FIRE-ENGINES, ETC., TO THE WAR DEPARTMENT,

RAILWAY STATION, DEPTFORD, AND 12 GARLICK HILL, CITY, E.C.

VENTILATION WITHOUT FLUES.

KUKLA'S PATENT STOVES,

At 18s., 25s., and 50s.

KUKLA'S newly-invented Deflagrator—the first and only perfect GAS STOVE. Guaranteed to burn without flue—without dust, smell, or smoke, producing a great and pure heat with the least expenditure of Gas.—*Vide Society of Arts' Journal.*

Patronised by the English and French Government.

Scientific in Principle,
Simple in Construction,
Healthy and efficient in use.

The Deflagrator Stove is cheap, portable, and suited for every situation; and from the principle on which it is constructed (viz., expanding to a sixfold volume the gas used) is capable of warming any given space more quickly and more thoroughly than any other means: while its addition forms a sure remedy for any ill-warmed or ill-ventilated apartments.

The 25s. Deflagrator warms a room of 2,000 cubic feet at a cost of 3d. per day.

The 50s. Deflagrator warms 5 to 6,000 cubic feet at a cost of 6d. per day (twelve hours).

Also, the Greenhouse Stove at 18s.

Patentee and sole Manufacturer, F. X. KUKLA, 194 Pentonville-road, London.

Country orders promptly attended to. Carriage free to any Railway in London.

Post-office Orders should be made payable to FRANCIS XAVIER KUKLA, General Office.

N.B.—Every Stove separately tested before sent out.

The New Gas Cooking Stove for 10 persons, price £3.

(103)

TO BRASS-FOUNDERS, ENGINEERS, &c.

THE PATENT PLUMBAGO CRUCIBLE COMPANY having completed the enlargement of their premises, beg to call the attention of all users and shippers of Melting Pots to the great superiority of the PATENT CRUCIBLES, which have been used during the last three years by some of the largest melters in England and abroad. In addition to their capabilities of melting an average of from thirty-five to forty pourings; they are unaffected by change of temperature, never crack, but can be used till worn out, requiring only one annealing for several days' work, and become heated much more rapidly than ordinary pots, effecting thereby a saving of more than fifty per cent. in time, labour, fuel, and waste. The Patent Plumbago Crucible Company also manufacture and import clay crucibles, muffles, portable furnaces, sublimate pans and covers, glass-pots, all descriptions of fire-standing goods, and every requisite for the assayer and dentists. For Lists, Testimonials, &c., apply to Battersea Works, London, &c. (43

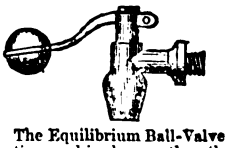
HYDRAULIC MACHINERY OF EVERY DESCRIPTION, FOR HOME USE OR EXPORT, UPON THE LARGEST, OR SMALLEST SCALE, MANUFACTURED, FIXED, OR LENT ON HIRE: AN EXTENSIVE STOCK KEPT READY FOR GENERAL PURPOSES.

(108)

HIGH-PRESSURE VALVE-COCKS,

LAMBERT'S PATENT.

Equilibrium Ball Valve. Cottage Closet Valve.



The Equilibrium Ball-Valve is simple and certain in its action, and is cheaper than the common cocks now in use.

The Cottage Valves are suitable for application to any kind of basin; and, as they shut against the pressure, no concussion in the pipes can possibly occur.

These cocks have been extensively and most successfully used in many towns, under continuous high pressure, varying from 100 to 350 feet; their efficiency and durability is, by experience, established.

THOMAS LAMBERT and SON,
Brass Founders, Short-street, New-cut, Lambeth.

GREAT ECONOMY IN GAS

EFFECTED BY MEANS OF

HART'S PATENT

ECONOMISING GAS BURNER

AND ILLUMINATING POWER DIFFUSER,

PRICE **2s. EACH.**

THIS very simple and complete apparatus is the great desideratum of the age for gas consumers. It can be attached to any gas chandelier, stand, or bracket, in a few moments, by the most inexperienced hand. It is impossible for it to get out of repair.

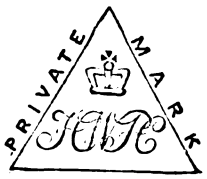
The saving effected by it is from 5 to 35 per cent., at the same time producing an illuminating power far superior to any other burner, varying from 10 to 150 per cent., as proved by experiments made with photometer (defraying its own cost in from one to three months), which must be seen to be believed, and can be demonstrated to any gas engineer, or other scientific man, at one moment's notice, on application at the Depôt,

69 FLEET STREET, LONDON.

To be had of all Gas Fitters in the Kingdom.

No Regulator of any kind required, neither will any Regulator diffuse the Illuminating Power, but, on the contrary, check its development.

NONE ARE GENUINE UNLESS



There being no other Burner before the public that does, truly and scientifically speaking, economise gas, the public are cautioned against Spurious Imitations.

BEARING PRIVATE MARK.

TESTIMONIALS.

"Polytechnic Chemical School, London.

"This is to certify, that I have carefully conducted a series of experiments with various gas burners in present use, and find that 'Hart's Patent Economising Gas Burner' is the most economical of all, producing, when compared with others, a saving of *forty per cent.* Signed this 14th day of December, 1858,

"309 Regent Street." "EDWARD J. GARDNER, Professor of Chemistry, &c., &c., &c.',

"7 Chester Street, Grosvenor Place, Pimlico.

"I have Mr. Hart's Gas Economising Burner fitted to every branch in my house, and can speak in the highest terms of its success. The light is perfectly steady, and the flame more brilliant, with perfect combustion, so that the air is by no means oppressive as formerly: the ceilings have no chance of being blackened, and the gilt frames and furniture cannot now, as before, be injured. I most warmly recommend their adoption. (Signed.)

"November 3rd, 1858." "WILLIAM V. PETTIGREW, M.D., Hon. F.R.C.S. of England, &c., &c., &c."

"Having tried Mr. Hart's Patent Gas Economising Burner, I do not hesitate to state, that it gives perfect satisfaction, and entirely dispenses with the use of any regulator whatever.

"From its perfect regulation of the pressure requisite for perfect combustion, it produces a white and steady light, without the slightest noise, *which proves its perfect combustion*:—for wherever there is a hissing, as is usual, there is a waste of gas—the gas being imperfectly burnt or 'fried'—dispensing its effluvia throughout the apartment.

"November 15th, 1858." (Signed.) "ANDREW STEINMETZ."

"Junior United Service Club, London, Secretary's Office, 21st January, 1859.

Sir,—After a long course of Experiments with your Patent Economising Gas Burners, the result of which is highly satisfactory, the Committee have decided on their adoption throughout the Club, and I herewith enclose order for same. I am, Sir, your obedient Servant,

"Mr. H. W. Hart, 69 Fleet Street." "HUBERT G. de CARTERET, Secretary."

"44 Gloucester Square, Hyde Park, January 21st, 1859.

"Major-General Moncrieff has had Mr. Hart's Patent Gas Burners fitted in his house for some weeks past, and has great pleasure in testifying to their efficiency. As far as Major-General Moncrieff can judge, they fully come up to the description given of them by the Patentee, and are very much superior to any burner Major-General Moncrieff has yet seen tried.

"To Mr. Herbert William Hart."

"176 & 177 Strand, London, W.C., January 18th, 1859.

Dear Sir,—I have much pleasure in certifying to the very satisfactory result of a trial of your Patent Gas Economising Burner.

"This Burner regulates and distributes the delivery of the gas in a manner to produce a very great amount of light, as well as to effect a considerable saving of gas, by preventing a large proportion of it from being blown through partially consumed, and which partial combustion is a double source of injury and annoyance—it soils the ceiling and deteriorates the atmosphere. I am, Dear Sir, very truly yours,

"To Mr. Hart, 69 Fleet Street." "(Signed.) SAMUEL SAINSBURY."

It is the continued remark of scientific men that HART'S PATENT ECONOMIZING GAS BURNER only requires to be known to be adopted.

Wherever there is a sufficient supply of Gas to produce a reasonable amount of light, HART'S PATENT ECONOMIZING GAS BURNER becomes an essential, obviating all objections to the use of Gas in private apartments.

HART'S PATENT ECONOMIZING GAS BURNER is considered by all scientific men to be the great desideratum of the age—the cheapest and most economical.

Hart's Patent Economising Gas Burner has been highly approved of by the Surveyor of Windsor Castle, and is now in use in various parts of that building.

To be seen in operation, and demonstrated upon at the Royal Polytechnic, Regent Street, and at the Depôt, 69 Fleet Street; also, to be seen in operation at the Royal Coloseum, Regent's Park. They are highly approved of by Dr. Bachhoffner. (123)

WATER GAUGES—WATER GAUGES.—Sir,—We find your German Gauge Tube superior to any other, and strongly recommend it. We were compelled to abandon the use of our water gauge until applying your glass tube.

WILCOX and Co., Millwall Pottery Company.

These Tubes are superior to all others; being a clear white, no mistake can arise in working. Guaranteed to stand a pressure of 500 lb.

Extensively used on all the principal lines.

To be had only of E. MOORE, 55 Upper Marylebone-street, W.; and 72 Great Titchfield-street, W.

*** Price List of Gauge Fittings, &c., on application. (98)

TO WIRE ROPE MAKERS.—ARCHIBALD SMITH is now prepared to GRANT LICENCES for the use of his PATENT ROPE MACHINERY, guaranteed to work at six times the speed of any other, and to save upwards of fifty per cent. in the cost of making. It is used by the most eminent makers, and was also in the manufacture of the Atlantic Cable.—Apply to 69 Princes-street, Leicester-square, W. (8)

GLASGOW.
Agricultural Implements of all kinds.
MOWING & REAPING MACHINES.
Price Lists free on application.
AGENTS WANTED. (32)

ARTESIAN WELLS, BORING TOOLS, PUMPS, &c. Engineers, Architects, Surveyors, Builders or others requiring a good supply of Water may have any quantity procured by W. SPELLER, 14 York-street, Blackfriars'-road, London, where may be had any quantity of Tools for Sinking or Boring, from 2 to 20 inches diameter, and from 100 to 2,000 feet depth; also Men and Tools to bore for Railroads, Minerals, &c., in any part of the world. Boring Tools and suitable Pipes for exportation, with full instructions for their use.

Builders, Contractors, Brickmakers, Barge and Ship Builders, and others, can be supplied with Wrought or Cast Iron Pumps, Double or Single, for excavation of Deep Wells, from 3 to 14 inches in the bore, and from 6 to 130 feet in length, to work by Hand or Steam Power.

Hot-water Apparatus for Conservatories, &c., on the most economical and improved principles.

Also Manufactory for Captain John Grant's much improved Cooking Apparatus. (44)

PUMPING MACHINERY.

GWYNNE AND Co., Engineers, London, manufacture and supply the following Machinery, of the most approved construction and with all the latest improvements:—Portable and Fixed Steam-Engines and Boilers of every description; Waterwheels, Windmills, Horse and Hand-power Machines; Pumping Machinery for the Supply of Towns, Cities, and Districts, and for the Irrigation of Coffee, Cotton, Indigo, Sugar-cane, and Rice Estates, for pumping out Coffer-dams, Canals, Dry Docks, Reservoirs, &c. They also manufacture and supply the Pumping and other Machinery for Paper, Pulp, and Fulling Mills, Breweries, Distilleries, Tanneries, Starch Works, Bleaching, Dyeing, and Calico Printing Works, Chemical Works, Silk, Cotton, and Flax Mills, and Manufactories in general. All Letters not paid will be refused. Illustrated Price Lists forwarded on receipt of Six Postage Stamps.—GWYNNE AND Co., Hydraulic and Mechanical Engineers, Essex-wharf, Strand, London.

For Exportation.—The above can be obtained through British Merchants, Shippers, and Colonial Agents. (24)

BY HER MAJESTY'S ROYAL LETTERS PATENT.

PATENT SPHERICAL SELF-ADJUSTING BEARINGS, which do not heat in work. The advantages possessed by these Bearings are:—

1st. They are Self-adjusting; and, consequently, can be put down by the most ordinary Mechanic.

2nd. They are not liable to heat, even at high speeds.

3rd. They remain constantly parellel to the Spindle; and, therefore, wear equally all across the Bearing.

4th. They require only a very small quantity of oil.

Engravings and Prices forwarded on application to the Patentees.

WALLIS & HASLAM,
Engineers and Iron Founders, North Hants Iron Works, Basingstoke. (121)

CLAYTON, SHUTTLEWORTH, AND CO.,

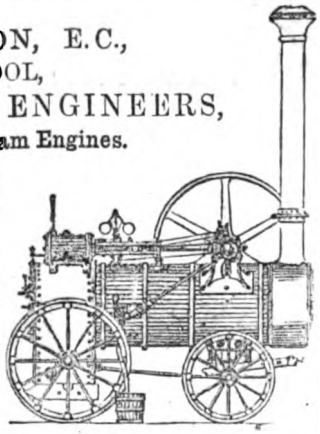
OF LINCOLN,

78 LOMBARD STREET, LONDON, E.C.,

AND 36 DALE STREET, LIVERPOOL,

AGRICULTURAL AND GENERAL ENGINEERS,

And Manufacturers of Portable and Fixed Steam Engines.



Combined Threshing Machines, which dress the corn ready for market at one operation. Grinding Mills, Saw Benches, Pumps for Irrigation and Mining purposes, with all necessary gearing for being driven by steam power. Full particulars and estimates given on application to the above address.

C. S. and Co.'s PORTABLE STEAM ENGINES are adapted for every purpose to which steam-power can be applied. When intended for winding, they are fitted with reversible link motion and winding gear. They are easy of removal, as may be seen by the engraving, and can be set to work immediately on arrival.

C. S. and Co. are now doing an extensive foreign and colonial business, and are prepared to send off engines and machinery of the before-mentioned kinds in a few days from the date of order. They would also call attention to the important *reduction in prices* made for the new year.

For Exportation.—The above can be obtained through British Merchants, Shippers, and Colonial Agents. (23)

IMPROVED MACHINERY FOR AGRICULTURISTS.

RICHARD GARRETT & SONS,

LEISTON WORKS, SAXMUNDHAM, SUFFOLK,

(ESTABLISHED A.D. 1778),

EARNESTLY solicit the continued support of their numerous Friends, Agriculturists, Shippers, and others; the additions made to their Works during the present year, in the erection of new sets of Workshops, fitted with the best mechanical appliances for producing Machinery of the most improved construction, expeditiously and economically, justifies their soliciting increased support, while their leading reputation as Inventors and Manufacturers of FIRST CLASS Agricultural Machinery, is a sufficient guarantee that every Machine supplied from Leiston Works will prove to the entire satisfaction of the purchaser.

R. G. & S. are now manufacturing the following Machines and Implements, which they guarantee to be thoroughly efficient in every respect:—

PORTABLE AND FIXED STEAM ENGINES. } From 4 to 40 Horse Power, suited for every kind of work
SELF-PROPELLING AND TRACTION ENGINES. } to which Steam Power is applied.

STONE GRINDING MILLS.
MORTAR AND PUG MILLS.
MILLWRIGHTS' WORK of all kinds.
SAWING MACHINERY, from 4 fo 20 Horse Power.
BRICK AND TILE MACHINES.

IMPROVED SETS OF FARM MACHINERY, for Large Occupations.
PORTABLE AND FIXED MACHINERY, for Thrashing and Dressing Corn.
THE PRIZE BOLTING AND OPEN-DRUM HORSE-POWER THRASHING MACHINES.
CORN DRESSING MACHINES, for Hand, Horse, Water, and Steam Power.
BARLEY AVELLING MACHINES.
CHAFF CUTTERS, for Hand, Horse, Water, and Steam Power.
PATENT TURNIP CUTTING AND PULPING MACHINES.

THE PRIZE CORN AND SEED DRILLS.
PRIZE CORN AND SEED DRILLS WITH MANURE APPARATUS.
PRIZE SEED AND MANURE DRILLS.
LIQUID, SEED, AND MANURE DROP DRILLS.
CHAMBER'S PATENT BROADCAST MANURE DISTRIBUTOR.
GARRETT'S PATENT HORSE HOE for all Crops.
PATENT REVOLVING HOES for Root Crops.
IMPROVED PLOUGHS AND REAPING MACHINES.
&c. &c. &c.

Of which full detailed particulars will be found in R. G. & SONS' ILLUSTRATED CATALOGUE, sent postage free to any address, in English, French, or German; and any of the above Machines will be shown in operation at R. G. & SONS' Farm, near the Works, on their receiving a few days' notice.

A Copy of R. G. & SONS' new COLONIAL LIST will be forwarded free to any of the Colonies, and Shippers will be supplied with these lists, with their names and addresses printed on, free of charge, by making application for the same.

ADDRESS—R. GARRETT & SONS, LEISTON WORKS, SAXMUNDHAM, SUFFOLK. (57)

WATER POISONED BY LEADEN PIPES.

"The above engraving represents accurately a section of a leaden pipe, which was employed for a short time in conveying water from a well on the grounds of Mr. Dick, of Bonchurch, Isle of Wight. The water has cut these deep pits almost through the pipe, and not only upon the portion which we have illustrated, but has formed similar chasms throughout the centire length."—*Expositor*.

Poisoned Water Preventable.

BY THE USE OF GUTTA PERCHA TUBING.

The Gutta Percha Company have been favoured with the following letter,

From Dr. MURRAY, Hull.

"It is impossible to conceive of anything more injurious, or destructive to the health of the community than the use of *leaden pipes* for the conveyance of water. The poisonous salts of lead thereby communicated are most insidious and subtle. I hail with gratitude the substitution of Gutta Percha Tubing. I have had the leaden pipe of my own house removed, and its place supplied with one of Gutta Percha. Nothing can be better. I have also recommended it to others, who have adopted the expedient.

Resistance for Frost.

The Gutta Percha Company have been favoured with the following Letters in reference to the non-conducting properties of Gutta Percha Tubing, in the resistance of Frost.

From J. ARMSTRONG, Esq., M.D., Gravesend.

"My private house, which was supplied with your Gutta Percha Tubing some five or six years ago, has never required the slightest attention; and previously, there was no winter passed that we were not deluged in consequence of the bursting of the leaden pipes."

From HENRY BROWN and SONS, Western Works, 108 Rockingham-street, Sheffield.

"We have now a positive proof of the frost-resisting properties of the Gutta Percha Piping. On our premises we have a leaden Pipe and a Gutta Percha one lying side by side. The leaden one has been completely frozen up at least ten days, and the Gutta Percha one is still unaffected.

GOVERNMENT SCHOOL OF MINES, Jermyn-street.—The following Courses of LECTURES are about to be commenced:—

MINERALOGY.—Forty Lectures on Mineralogy, by Warrington W. Smyth, M.A., F.R.S., to be delivered on Mondays, Tuesdays, Thursdays, and Fridays, at 3 p.m., commencing 14th February. Fee for the Course, £2.

GEOLOGY.—Thirty Lectures on Geology, by Professor Ramsay, F.R.S., to be delivered on Mondays, Tuesdays, and Wednesdays, at 2 p.m., commencing 14th February. Fee, 30s.

NATURAL HISTORY.—Fifty Lectures on Natural History, by Professor Huxley, F.R.S., to be delivered on Wednesdays, Thursdays, and Fridays, at 10 a.m., commencing 16th February. Fee, £2.

APPLIED MECHANICS.—Thirty-six Lectures on Applied Mechanics, by Professor Willis, M.A., F.R.S., to be delivered on Wednesdays, Thursdays, and Fridays, at 12 o'clock, commencing 16th February. Fee, 30s.

TRENHAM REEKS, Registrar. (127)

LECTURES TO WORKING MEN.—Government School of Mines, Jermyn-street.—The Third Course of Six Lectures on the "History of Geology," by Professor RAMSAY, F.R.S., will be commenced on Monday, February 21st, at Eight o'clock. Tickets may be obtained by Working Men only, on Monday, 14th inst., from 10 to 4 o'clock, upon payment of a Registration Fee of 6d. Each applicant is requested to bring his name, address, and occupation, written on a piece of paper, for which the Ticket will be exchanged.

TRENHAM REEKS, Registrar. (140)

ENGINEERING AND MECHANICAL DRAWING CLASSES.—Instruction given in Engineering and Mechanical Drawing, comprising the preparation of plans, elevations, and sections of marine and locomotive engines, with the detail and working drawings; also the method of delineating screws, bevel wheels, &c.; orthographical projection, and tinting, shading, and colouring taught.—For prospectuses of the Day and Evening Classes apply to Mr. T. J. HILL, at the offices, 15, Old-street, City-road. (73)

TO MARINE ENGINEERS, OR SHIP-BUILDERS.

THE PROPRIETOR of a VALUABLE PATENT for Double-expansive Marine Engines (by which great economy of space and fuel is obtained) is desirous of entering into arrangements with a respectable firm for the construction of the same. An adequate portion of the patent-right would be assigned by the advertiser to any firm taking the matter up; and he would render all assistance in his power, either in London or elsewhere, amongst ship-owners (to many of whom he is well known), in obtaining contracts, &c. Unexceptionable references given. Address C. E., MECHANICS' MAGAZINE Office, 166, Fleet-street. (76)

HART & SON, MALLEABLE IRON-FOUNDERS, 4 Vine-street, York-road, Lambeth. Orders for Malleable Iron Castings executed within a week. (77)

INDIA-RUBBER VALVES FOR STEAM ENGINES, PUMP PACKING, &c.—Explanatory Drawings and Information as to the best modes of fitting and arranging the above, and all other Mechanical Applications of VULCANISED INDIA-RUBBER, are furnished post-free by

CHARLES MACINTOSH & Co., Patentees, Cambridge-st., Manchester, and 3 Cannon-st. West, London.
MANUFACTORY and DEPOT, Cambridge-st., Manchester.
GENERAL WAREHOUSE, 3 Cannon-street West, London, E.C.—C. M. and Co.'s only Establishments. (139)

STEAM ENGINES FOR SALE.

PORTABLE STEAM ENGINES, from 6 to 12 horse power,
STATIONARY STEAM ENGINES, from 4 to 50 horse power,
TUBULAR BOILERS, from 4 to 50 horse power,
CORNISH BOILERS, from 4 to 50 horse power,

Are in hand, and can be despatched on eight days' notice. Prices moderate. Workmanship and Material of the best description.

Apply to R. THORNTON & Co., St. Leonard's Iron Works, Edinburgh. (60)

GLADSTONE & Co., CONTRACTORS and ENGINEERS.
2 John-Street, Minories, London, E.C.,

Are prepared to ESTIMATE FOR and CONSTRUCT BRIDGES, PIERS, JETTIES, &c., in Iron, Wood, or Stone. Also to supply Cranes, Girders, Turntables, and Railway Work and Plant generally. (56)

CHUBB'S LOCKS, FIREPROOF SAFES, CASH AND DEED BOXES.
Complete lists of sizes and prices may be had on application.
CHUBB AND SON,
57 ST. PAUL'S CHURCHYARD, LONDON;
28 Lord-street, Liverpool; 16 Market-place, Manchester, and Wolverhampton. (4)

BRICKS.

TO BE LET, with immediate possession, in consequence of the death of the proprietor, J. M. Paine, the DIPPENHALL SILICA FACTORY, erected for the purpose of making improved Fire Bricks, Building Bricks, Paving Tiles, &c., &c., from the Soluble Silica Rock.

Apply to view the Buildings and Bricks to G. H. Ogston, Esq., Resident Manager, Dippenhall, Farnham, Surrey; and for terms, to Messrs. Nicholls and Potter, Solicitors, Farnham. (125)

TO ENGINEERS, ARCHITECTS, PATENT AGENTS, &c.

PHOTOGRAPHS OF THE HIGHEST CLASS and of any size, taken and reproduced at a most moderate rate of charge. Reproductions of faultless accuracy, of Machinery, Models, Drawings, &c. Orders attended to in town and country. Estimates forwarded.
SPENCER, READ, & Co., 4 Agar-street, Strand. W.C. (90)

FIRE BRICKS.—THE FARNHAM INDESTRUCTIBLE SILICIOUS FIRE BRICKS have been greatly REDUCED in PRICE, and will be delivered at the Nine Elms Station, London, at 90s. per 1,000.—Address, G. H. OGSTON, J. M., Paine's Silica Works, Farnham, Surrey. (35)

VITRIFIED BLUE BRICKS are delivered at the Nine Elms Station, London, at 80s. per 1,000.—Address, G. H. OGSTON, J. M. Paine's Silica Works, Farnham, Surrey. (36)

"Everybody likes good Beer,
But everybody don't know where to get it."

VICTORIA PALE ALE IS THE BEST DINNER ALE OF THE DAY, 18 Gallons, 20s., 9 ditto, 10s.

HOUSEHOLD ALE, Brewed expressly for Private Families, 1s. per Gallon.

DOUBLE STOUT, 13s. 6d. per Nine-Gallon Cask. This is a generous beverage, and is strongly recommended to persons who require a nourishing diet.

HENRY LOVIBOND, Cannon Brewery, Chelsea. (134)

EDWIN JEWITT, ENGRAVER ON WOOD AND DRAFTSMAN, 1 Pickett-place, Strand, near Temple-bar. Engineering, Scientific, and Mechanical Designs accurately engraved. Manufacturers and Tradesmen's Catalogues Illustrated. W.C. (84)

TO CARD CASE MAKERS.

WANTED a Good Workman in the Card Case and Pencil and Brush Case Trades, to undertake a large quantity of work of a similar character.—Apply to W. W., MECHANICS' MAGAZINE Office, 166 Fleet Street. (131)

TO ENGINEERS, INVENTORS, AND OTHERS.

A PRACTICAL ENGINEER of long standing prepares Original Drawings, Copies, and Tracings. Advice and Assistance given to Inventors in working out their Plans. Pupils taught privately. Terms moderate.
Apply to J. J., 171 Strand. (138)

STEAM ENGINES.

FOR SALE, a superior HIGH PRESSURE HORIZONTAL STEAM ENGINE of 6-horse power, 8-inch cylinder, and 1-foot 6-inch stroke. One of 8-horse power, 10-inch cylinder, and 1-foot 6-inch stroke. One of 10-horse power, 12-inch cylinder, and 2-feet stroke. Two of 14-horse power, 14-inch cylinders, and 2-feet stroke; and one of 30-horse power, 20-inch cylinder, and 3-feet stroke.

Apply to Messrs. PAGE and CAMERON, 64 Old Broad Street, E. C., London. (124)

ENGINEERING BUSINESS FOR SALE.

OWING to the continued ill health of the Proprietor, the first-class business of an Engineer and Crane and Block Maker is offered for sale. It has been established in the Metropolis for nearly 30 years, and has enjoyed extensive patronage amongst Brewers, Manufacturers, Warehousemen, and others, in and about London; the business done amounting to nearly £8,000 per annum. About £3,200 would be required, (part of which, however, may remain for any reasonable time on good security,) which is the bare value of the tools, patterns, and stock in trade. The premises, including good dwelling-house, very conveniently situated, and capable of accommodating from 60 to 70 hands, are held upon a long lease, at an extraordinary low rental, not exceeding £100 per annum, taxes included. Many of the tools are nearly new, and of the best construction. The present proprietor, who relinquishes the business solely on account of ill health, would give every assistance in his power to those succeeding him; and as his foreman, who has been with him for nearly ten years, is thoroughly acquainted with the practical parts of the business, any gentleman desirous of commencing as a manufacturing engineer would find the present a very favourable opportunity. As all accounts have been, for many years past, collected quarterly, a very small amount, say £800, would suffice as working capital. Full particulars may be obtained by application to E. E. ALLEN, Esq., MECHANICS' MAGAZINE Office, 166 Fleet Street, E.C. (130)

TO ENGINEERS' TOOL MAKERS, AND OTHERS.

THE ADVERTISER is desirous of meeting with an engagement as TOWN or DISTRICT AGENT for an Engineers' Tool Maker, or firm whose business lies amongst Engineers and practical men. He is an Engineer by profession, has for many years been engaged in bringing into operation several inventions, and can give unexceptionable references. A very moderate fixed salary only expected. Address M. C., MECHANICS' MAGAZINE Office, 166 Fleet-street. (78

ENGINEERS' TOOLS.

FOR SALE, a Self-acting Slide LATHE, 11-inch Centres, and Bed 12 feet long, complete; and TWO PORTABLE PUNCHING and CUTTING MACHINES, one suitable for ½-inch plates, and the other for ⅜-inch plates, both adapted for steam or hand power.

Apply to Messrs. PAGE & CAMERON, 64 Old Broad Street, E.C. (117)

THORLEY'S FOOD FOR CATTLE.—Every person having an interest in domestic or farm animals should obtain a supply of this celebrated and economical food, which will prove invaluable during the approaching season. For keeping horses in good condition, it is unequalled. Pigs fatten with surprising rapidity upon it, and their flesh increases in flavour and value. Cowkeepers will find great advantage in the increased quantity and improved quality of the milk during its use. All animals are benefited by it. A pamphlet on this interesting subject, accompanied by Testimonials from the principal Nobility, Gentry, and Agriculturists, forwarded on application. In Casks containing 448 Feeds (Measures enclosed), Price 50s., carriage paid to any Railway Station in the United Kingdom. Post Office Orders payable to JOSEPH THORLEY, 77 Newgate Street, London.

N.B.—The public are cautioned against being imposed upon by worthless imitations. (132)

TO STEAM SHIP OWNERS, ENGINEERS, AND OTHERS.

How's Patent Steam Engine Counters, can be read at sight.

These Counters register the number of revolutions made by an engine or other mechanism. They may be used for ascertaining the duty of Pumping Engines and Water-wheels; the revolutions on board a steam-vessel; to calculate the slip of the propeller; and in a locomotive to test the slip of the wheels.

How's Patent Salinometer, for Steam Boilers using Salt Water.

By these, the density of the water in the Boiler is at all times accurately shown, and a saving of boiler and fuel is effected. They are adopted by the Admiralty, the Honorable Trinity Corporation, and others. Copies of Testimonials from Messrs. Penn, Messrs. Maudslay, and others, will be forwarded on application.

How's Engine-Room Telegraph, for communicating between Captain and Engineer. Society of Arts Prize Medal, 1855.

This is a Mechanical Telegraph, and by its peculiar construction, error or misunderstanding is rendered impossible. It is now extensively adopted, and gives great satisfaction.

How's Patent Fresh Water Apparatus for Ships' Use.

This apparatus is designed for the distillation of Fresh from Salt Water; and on long voyages, and where the supply of water is scanty, it will be found invaluable. Testimonials may be seen.

Patent Steam Pump and Fire-Engine for Ships' Use.

This Steam-pump occupies but a small space; works perfectly noiselessly, and throws an immense volume of water. An Illustrated Circular of Fresh Water Apparatus and Steam-pump combined, free on application.

How's Patent Machine for Cutting Bolts, Rods, Spindles, Wire, &c.

Simple in construction, inexpensive, occupies but little space, and will not easily get out of order.

A Pamphlet Illustrative of the above, sent free by post, on application to

A. P. HOW, ENGINEER,

81 MARK LANE, LONDON.

EVERY DESCRIPTION OF ENGINEERS' TOOLS, ENGINE ROOM STORES, &c., &c., SUPPLIED.

(89)

SCOTT'S

PATENT GRASS SEED SEPARATOR,

which entirely extracts the Seeds of "COUCH," "TWITCH," "SPEAR," or "HAIR" GRASS, and other impurities from

PERENNIAL AND ITALIAN RYE-GRASS, &c.,

AND

SCOTT'S PATENT CARROT SEED BEARDING

AND

CLOVER AND TREFOIL MILLING OR DRAWING MACHINE,

which effectually removes the beard from Carrot Seed, rendering it fit for sowing with facility by drill or otherwise, and by the separation of abortive or diseased grains vastly increases its vegetative per centage. By a slight modification it is applicable to the other purposes before mentioned.

These Machines were admittedly the most novel, and, at the same time, the most useful and important to the Farmer of any exhibited at the late SMITHFIELD CLUB SHOW.

They may be seen at work at the Establishment of the Manufacturer,

Mr. T. MIDDLETON, Engineer, Southwark.

Communications to be sent to the Patentee, J. SCOTT, 111 Drummond Street, Euston Square, London, N.W. (48.)

THE ROYAL AGRICULTURAL SOCIETY OF ENGLAND'S

FIRST PRIZE REAPER.

BURGESS & KEY, PATENTEES AND SOLE MAKERS, 95 NEWGATE STREET, LONDON.

MANUFACTORY, BRENTWOOD, ESSEX.

BURGESS & KEY'S extensive Manufactory is wholly occupied in the Manufacture of

REAPING MACHINES AND GRASS MOWING MACHINES,

upon which they have concentrated their efforts since the year 1851. Their practical experience enables them to produce Reaping Machine which can be depended on by the Farmer.

Owing to the excessive demand for last season, many orders were left unexecuted. BURGESS & KEY therefore earnestly request that orders for next season (1859) be sent as soon as possible, otherwise they cannot guarantee to deliver in time.

Price £42 10s. Net Cash, at the Works, complete with Conical Screw Divider for long Grain; without the Conical Screw, £40. Extra Knife, £1 5s. If other extras are supplied they are charged for. A man sent to start the Machine, if required, on payment of his expenses.

BURGESS AND KEY'S GRASS-MOWING MACHINE

(ALLEN'S AMERICAN PATENT).

Before introducing this Machine to the English public, BURGESS & KEY determined to fully test its capabilities, and the all-important point—durability. One Machine cut, on the farm of Mr. C. Hall, Havering, Romford, Essex, 83 acres Grass; and the same Machine afterwards cut, on the farm of Mr. Tabrum, Bovis Hall, near Brentwood, Essex, 100 acres Grass, and 20 acres Clover. The work done was declared to be better and lower than the scythe, and at the rate of 1 acre per hour. Orders have been received from both those Gentlemen, and numerous others, for Machines for next season. Price £30.

BURGESS & KEY'S Manufactory is entirely devoted to REAPING MACHINES and MOWING MACHINES.

95 NEWGATE STREET, LONDON.—MANUFACTORY, BRENTWOOD, ESSEX.

RANSOME'S PATENT IMPERISHABLE SILICIOUS STONE.—Chimneypieces, Balustrades, Capitals, Trusses, Terminals, Fountains, and Vases; also, Enamelled Stone Chimneypieces, of great beauty and novelty, at reduced prices. Monumental or Mural Memorials, Grave Stones, Space Markers, and Indicators for Cemeteries, &c., of every description, at the lowest price.

RANSOME'S PATENTED PROCESS FOR PRESERVING STONE.—Invaluable in its application to Public Edifices and Private Residences. By this process the softest and most friable stone can be rendered impervious and imperishable, and decay at once arrested and prevented.

RANSOME'S PATENT STONE FILTERS FILTERING SLABS.—Manufactured for every Private or Domestic purpose, for Manufactories, Public Companies, Shipping, &c. Several hundred thousand gallons of water are filtered daily by Ransome's Patent Stone Filtering Slabs, for the town of Southampton. They have also been adopted by the Admiralty, the Board of Ordnance, the Colonial Land and Emigration Commissioners, and other Public Bodies for several years; also in the City of Rotterdam, with the most perfect success.

For particulars, specimens, illustrations, and agencies, apply to

Mr. FREDERICK RANSOME,

WHITEHALL WHARF, CANNON ROW, WESTMINSTER;

OR PATENT STONE WORKS, IPSWICH.

A liberal discount allowed to the Trade or to Shippers.

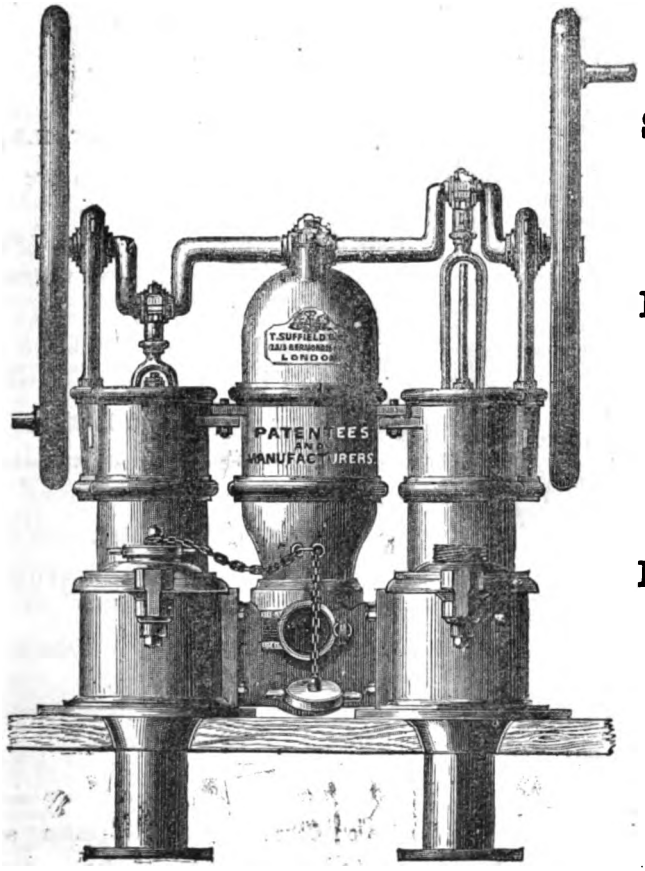
T. SUFFIELD AND CO.

Call the particular attention of

SHIP-OWNERS. SHIP-BUILDERS, AND COMMANDERS OF STEAM AND SAILING VESSELS,

to the Simple and Efficient Arrangements of their

PATENT PUMPS.



Ships' Pumps

AND

Fire Engines,

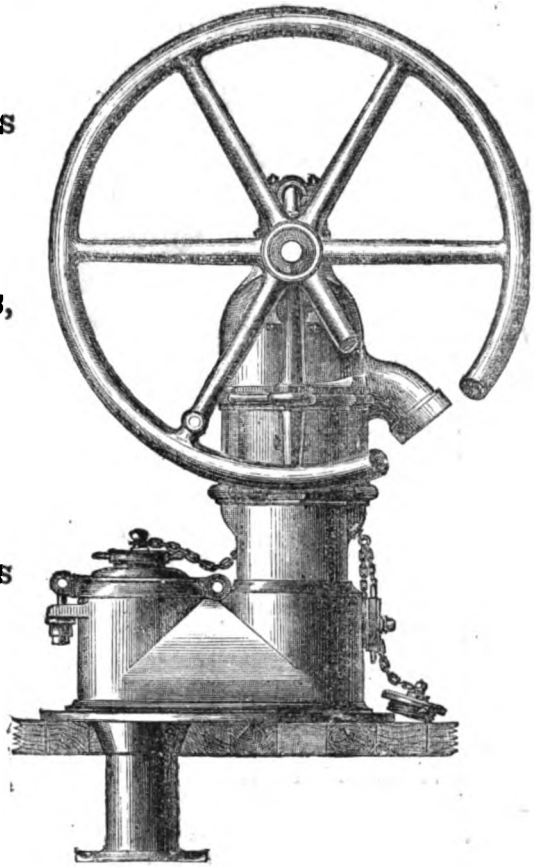
Fixed and Portable.

WITH

Patent Valves

AND OTHER

Improvements.



These Pumps are free from that liability to choke which is common to other Pumps, and their Working Parts are not susceptible of derangement either from wear or from being long out of use. They pass entirely through them, with ease, any substance that may enter the Suction Pipes. The Novelties in these Pumps are their adaptation to the varied duties of Ships' Pumps; the facilities they afford for Cleansing the Suction Pipes, and for Sounding or Examining the Valves; the readiness with which they may be used for Ventilating the Bilge, or for acting as a Syphon either for Watering the Ship, or for extinguishing Accidental Fires on board; the rapidity with which they can be converted into Fire Pumps, or be applied to the Washing of Decks; and their capability of Pumping from Several Compartments.

T. SUFFIELD AND CO.

Also respectfully solicit the attention of STEAM SHIP BUILDERS and OWNERS to their Large and Varied STOCK of

ASSORTED STORES FOR MARINE PURPOSES.

They keep a Large Stock of Goods, of their own Manufacture and from the Best Makers, constantly on view; so that by a visit to their Works or Depôt, much valuable time may be saved by Managers, Engineers, and other Gentlemen who may require such Stores, together with a further saving in the cost of such Articles.

WORKS PUBLISHED BY BLACKIE AND SONS.

RAILWAY LOCOMOTIVES.

THEIR PROGRESS, MECHANICAL CONSTRUCTION, and PERFORMANCE, with the recent Practice in England and America. Illustrated by an extensive Series of Plates, and numerous Engravings on Wood. By DANIEL KINNEAR CLARK, C.E. To be completed in about 22 parts, imperial 4to, 2s. 6d. each.

This work will combine the Locomotive Section of the Author's Treatise on Railway Machinery, with extensive additions illustrating the practice of English Locomotive Engineers of the present day, and presenting the most recent attainments in American practice. It will also include the consideration of a variety of questions bearing upon the improvement and economical working of the Locomotive.

Parts 1 to 12 now ready.

RAILWAY MACHINERY.

A Treatise on the Mechanical Engineering of Railways; embracing the Principles and Construction of Rolling and Fixed Plant, in all departments. Illustrated by a Series of Plates on a large scale, and by numerous Engravings on Wood. By DANIEL KINNEAR CLARK, C.E. 2 vols., half morocco, £4 15s.

RECENT PRACTICE IN THE LOCOMOTIVE ENGINE.

Being a Supplement to "Railway Machinery." Comprising the most recent Improvements in English Practice, and Illustrations of the Locomotive Practice of the United States of America. By DANIEL KINNEAR CLARK, C.E. To be completed in Eight Parts, imperial 4to, 2s. 6d. each.

This work will consist simply of the new portion of Railway Locomotives announced above. It is published separately for the benefit of those who already possess the Author's Work on Railway Machinery.

Parts 1 to 4 now ready.

BLACKIE & SON, Warwick-square, City, London; and all Booksellers. (126)

This Day,

THE PATHFINDER: a Weekly Journal of Political, Social, and Religious Reform. Conducted by P. W. PERFITT. Published by JAMES PATTIE, 31 Paternoster-row, and by G. GLAISHER, 470 Oxford-street. (96)

NEW EDITION OF DR. HYMER'S TRIGONOMETRY.

Just published, in 8vo, price 8s. 6d. cloth.

A TREATISE on PLANE and SPHERICAL TRIGONOMETRY, and on TRIGONOMETRICAL TABLES and LOGARITHMS; together with a selection of Problems and their Solutions. By J. HYMERS, D.D., late Fellow and Tutor of St. John's College, Cambridge.

Fourth Edition, Revised.

London: LONGMAN, BROWN, & CO., Paternoster-row. (135)

LUND'S MENSURATION AND GEOMETRY.

Just Published, Fcp. 8vo, Price 3s. 6d. Cloth.

ELEMENTS OF GEOMETRY AND MENSURATION, with Easy Exercises, designed for Schools and Adult Classes: Part III. GEOMETRY combined with ARITHMETIC MENSURATION. By the Rev. T. LUND, B.D., formerly Fellow of St. John's College, Cambridge; Editor of "Wood's Algebra." In the same Series,

I. GEOMETRY as a SCIENCE (a short reformed Euclid), 1s. 6d.

II. GEOMETRY as an ART, fcp. 8vo., 2s.

Parts I. and II. together, 3s. 6d.; I. to III. together, 7s.

"A BETTER introduction to geometry can hardly be imagined; and we are glad to find it is published at so reasonable a price, because it is a work which ought to be used extensively in our national schools and schools of design, and widely circulated among our manufacturing population."—ATHENÆUM.

London: LONGMAN, BROWN, & CO., Paternoster-row. (141)

NEW EDITIONS OF NESBIT'S MENSURATION AND LAND-SURVEYING.

A New and Improved Edition, augmented by a Treatise on Levelling, in 12mo., price 6s. bound,

A TREATISE ON PRACTICAL MENSURATION, in Ten Parts: containing—

- The most approved Method of Drawing Geometrical Figures.
- Mensuration of Superficies.
- Land-Surveying.
- Mensuration of Solids.
- The Use of the Carpenter's Rule.
- Timber Measure, in which is shown the Method of Measuring and Valuing Standing Timber.
- Artificers' Works, illustrated by the Dimensions and Contents of a House.
- Mensuration of Haystacks, Drains, Canals, Mairpits, Ponds, Mill-dams, Embankments, Quarries, Coal-heaps, and Clay-heaps.
- Conic Sections and their Solids.
- The most useful Problems in Gauging, according to the New Imperial Measures.
- Plane Trigonometry, with its application to the Mensuration of Heights and Distances.
- Trigonometrical Surveys.
- A Dictionary of the Terms used in Architecture.

By A. NESBIT. New Edition, enlarged and greatly improved. To which is added, a Treatise on Levelling. The whole illustrated by nearly Seven Hundred Practical Examples, and nearly Three Hundred Woodcuts.

KEY to NESBIT'S PRACTICAL MENSURATION: containing Solutions to all Questions which are not answered in that work; with Reference to the Problems, Rules, and Notes, by which the Solutions are obtained. New Edition, corrected and greatly improved. 12mo, price 5s. bound.

By the same Author, New Edition, 8vo, with Plates, Woodcuts, and Field-Book, price 12s.

TREATISE on PRACTICAL LAND-SURVEYING. Corrected and improved, with the addition of Plane Trigonometry, including the use of the Theodolite, and Railway Surveying, Railway Engineering, Levelling, Planning, Laying out Curves, &c. By T. BAKER.

London: LONGMAN, BROWN, & CO., Paternoster-row. (142)

Just Published. Price Three Shillings.

CARPENTRY.

CARPENTRY AND FRAMING, Copiously Illustrated with Plates and Descriptive Letter-press. By ROBERT SCOTT BURN.

W. and R. CHAMBERS, London and Edinburgh. (137)

Price 6d. Post free for Six Stamps,

SCREW PROPULSION: a Description, with Drawings of GRIFFITH'S PATENT SCREW PROPELLER, with all its recent improvements, showing its advantages over all others. With Directions for its application and use.

"Well worthy of perusal."—MECHANICS' MAGAZINE.

London: MATTHEW SOUL, 3 Leadenhall-street. (129)

WROUGHT IRON BRIDGES.

This day, with numerous detail Plates, 8vo, cloth, Price 15s.

THE CONSTRUCTION OF WROUGHT IRON BRIDGES: By JOHN HERBERT LATHAM, M.A., Civil Engineer.

From the "Athenæum."

"The great merit of Mr. Latham's book is that it deals with practice more than theory. All the calculations in his book connected with the strength of girders are based upon their actual application and working. . . The present publication, which abounds in practical investigations into girderwork in all its bearings, will be welcomed as one of the most valuable contributions yet made to this important branch of engineering."

Cambridge: MACMILLAN & Co.; and 23 Henrietta-street, Covent-garden, London. (122)

TO INVENTORS AND PATENTEES.

MESSRS.

ROBERTSON, BROOMAN, & Co.,

Civil Engineers

AND PATENT AGENTS,

REMARKS.—Manufactured Iron continues firm. A slight fall has occurred in Scotch Pig-iron, and at the moment the tendency of this article is downward. Copper is firm. Lead is also firm and evinces a tendency to advance. Spelter we quote a shade lower. The general tone of business is good.

LAWRIE AND HAGGER, Metal Brokers.

33 Lombard-street, E.C.

LIST OF MISCELLANEOUS TENDERS INVITED, AND ENGAGEMENTS OPEN.

RAILWAY WORKS, *Dundalk, Enniskillen.*—Tenders for constructing branch line from Shantonah to Gaole-hill, to March 1. Drawings at Engineer's office, London-bridge.

RAILWAY STATION, *Horsham.*—The directors of London Brighton, and South Coast Railway will receive tenders for erection of new station and warehouse at Horsham. Specifications at engineer's office, London-bridge Terminus; tenders to Secretary there by noon, 24th inst.

HARBOUR, *Scotland.*—Contractors wanted for excavation and completion of a basin, and for building of a sea-wall at Elgin and Lossiemouth Harbour; plans, &c., prepared by J. Abernethy, Esq., C.E., London, and may be seen on application at the town clerk's office, Elgin, or at Harbour office, Lossiemouth. Tenders to Mr. Duff, town clerk, Elgin, to noon, 5th March.

CHURCH, *Warrington.*—For restoration and enlargement of Warrington Church, Lancashire. Plans, &c., at the architects, Messrs. Francis, 38 Upper Bedford Place, Russell Square, London; and at the vestry room, Warrington. Tenders on March 1, to Rev. Wm. Quekitt, Rectory, Warrington.

TRADES, *Government.*—The Government invite tenders for the following trades in the Woolwich Royal Engineer district, from 1st April, 1859, to 31st March, 1862:—Bricklayers, masons, paviors, carpenters, and upholsterers, plasterers, slaters, plumbers, smiths, and ironmongers, painters, glaziers, and paperhangers and gasfitters. Schedules and forms from clerk of works at Royal Engineer Office, Grand Depôt, Woolwich, to 26th inst. Tenders to director of contracts, War Office, Pall Mall, noon, 7th March, marked "Tender for Artificer's work, Woolwich district." One contract for the Woolwich district will embrace all the above trades.

COAST-GUARD STATION, *Hoylake.*—For erection of a station at Hoylake, Cheshire. Drawings, &c., at Admiralty Coast-guard Office, 18 Spring Gardens, London, or at Watch Room, Hoylake, to 19th inst. Tenders at first-named place by noon 21st, directed to Commodore Comptroller General of Coast-guard.

GOVERNMENT SCHOOLS, *Woolwich.*—For alterations, &c., to Regimental Schools, Greenhill, Woolwich. Drawings, &c., at Royal Engineer Office, Royal Artillery Barracks, to Wed., Feb. 23. Tenders to Director of Contracts, War Office, Pall Mall, to noon, 28th inst. Time for completion extended to nine months.

PRISONS, *Canterbury.*—An additional prison for Kent at Canterbury, to contain 100 cells, and also various alterations to entrance lodge and sheds in the tread-wheel yard at Canterbury county prisons. Plans, &c., at offices of Messrs. Whichcord and Blandford, architects, Maidstone, and after 21st inst. copies at county gaol, at St. Augustine's, Canterbury. Tenders to architects by 11 A.M. 2nd of March, persons tendering to be in attendance at the Courts of Justice, Maidstone, at ½ past 12 that day.

ADDITIONAL PRISON, *Maidstone.*—The justices for Kent also invite tenders for a prison to contain 140 cells, and also for various alterations to the entrance lodge, &c. Particulars and dates as in preceding notice.

SEWERAGE WORKS, *Stroud.*—The Stroud (Gloucestershire) L. B. of Health invite tenders for sundry main sewers, purifying tanks, &c. Drawings, &c., at office of Mr. J. H. Taunton, M. I. C. E., Brimscombe House, Stroud, after 16th inst. Tenders to Clerk of Board to 28th inst.

STREETS, *Tipton.*—For making two streets at Tipton. Spec. at offices of Tipton L. B. of Health, Church-st., Tipton, to which place (for the Clerk) tenders must be sent by 22nd inst.

TOWN HALL, *Folkestone.*—For new Town Hall, Council House, Court House, Cells, and Buildings, and Market Houses and Market Places, at Folkestone. Drawings, &c., at offices of Mr. J. Messenger, architect, 9 Spring Gardens, London, S.W.; or at Mr. R. T. Brockman, Town Clerk, 5 West Cliff-terrace, Folkestone.

RECTORY, *Essex.*—For new Rectory-house, Parochial-schools, and Residence, at East Mersea, Essex. Plans, &c., at Mr. Rickwood's, 98 and 99 High-st., Colchester. Tenders to Feb. 15.

SCHOOLS, *East and West Rudham.*—For erection of East and West Rudham Schools. Plans at Messrs. Clowes and Flowerden, St. Andrew's Plain, Norwich.

HOUSES, *Dorercourt.*—For alterations to two houses on Dovercourt Cliff, Essex, converting them into an hotel. Plans, &c., at office of Mr. H. Darker, architect, Dovercourt. Tenders to Feb. 19.

OFFICES, *Coventry.*—For erection of warehouses, salerooms, and out-offices, in Much Park-street, Coventry. Plans, &c., at offices of Mr. Neville, Palace-yard, Coventry. No date.

CHAPEL, *Birkenhead.*—For erection of a chapel, schoolroom, &c., in Parkfield, Birkenhead. Plans, &c., at house of Mr. R. Jones, Tranmere. Tenders to Feb. 14.

STONE REREDOS, *Suffolk.*—Sculptors and carvers may tender for a stone Reredos at Hadleigh Church, Suffolk; drawings, &c., at office of architect, 12 Bishopsgate-street Without, and Bishop's Stortford, to 15th inst.

SCHOOLS, &c., *Luton.*—For a school, teachers' residence, &c., at Caddington, near Luton, Bedfordshire. Plans, &c., at offices of H. Holyoak, architect, Luton, Bedfordshire. Tenders there by 4 on 23rd inst.

COALS, *for Malta.*—For delivering into store at H.M. Naval Yard at Malta 13,000 tons of South Wales coals for H.M. steam vessels. Conditions, &c., at Storekeeper's office, Somerset Place. Tenders to two o'clock, 18th March, when persons tending, or agents, must be in attendance. Security £4,000, two sureties.

COALS, *for Gibraltar.*—For the Naval Yard at Gibraltar 3,500 tons of South Wales coals for H.M's. steam vessels. Conditions, &c., from Storekeeper General, Somerset Place. Tenders at 2 on the 15th inst. Attendance in person or by agent. Security £1,000, two sureties.

HERTFORDSHIRE.—The Skipton L. B. of Health will receive tenders for brick sewers, pipe sewers, manholes, gullies, ventilating shafts, flushing wells, &c. Plans, &c., to 14th inst., at the office in Hereford of Mr. T. Curley, C.E., and for seven days after at office of Mr. T. Heelis, Clerk to Board, Skipton. Tenders to Clerk by 23rd inst.

COALS, *for Greenwich Hospital.*—For 2,700 tons of either of undermentioned coals:—Best coals; Stewarts, Haswell, Hettons, South Hettons, at per ton, or Silkstone coal as supplied by the Great Northern Railway, at per ton. Forms, &c., at Mr. Stewart's office, Greenwich Hospital. Tenders by noon 23rd instant, persons or agent must attend.

ARCHITECT'S PLANS, *London.*—For the enlargement of Orphan Working Schools, Haverstock Hill. A premium of £50 for the most approved plan, and £30 for the Second; or instead of premium the Author of successful plan to be employed. Particulars at the offices, 32 Ludgate Hill, London, E.C.

CAST IRON PIPES, *London.*—Estimates required for supply of light cast iron eight-inch pipe, in 6ft. and 3ft. lengths, not more that 12 lbs. to foot, with a flange half an inch deep, one-sixth of an inch thick at each end. Terms, cash, address H.N., Care of Mr. Egleton, 169 Fleet Street, London.

TEMPORARY SURVEYOR, *Swindon.*—The Swindon Union want a person to superintend the building and laying down of several brick culverts, with pipe-drains, &c. Apply, stating terms per week, with references, to Mr. Haynes, Inspector of Nuisances, Swindon, by the evening of 17th inst.

TURNTABLE, *Chester.*—The Chester General Station Committee will receive tenders for a 42-feet turntable. Plans, &c., at offices. Tenders &c., before twelve o'clock Feb. 18. The committee have on sale 200 tons of old iron; ten 15-feet turntables, one 30-feet ditto, and a quantity of brackets for supporting lamps, each 2 feet 6 inches in length. Information of R. L. Jones, gen. man.

TO FITTERS.—Three good workmen wanted to make Self-acting machinery for turning and nicking wood Screws; also an engineer wanted. Apply to Messrs. Hadden and Hitchen, Glover-street Works, Birmingham.

TO IRON ROLLERS.—Wanted immediately for Mexico, a first-rate roller of iron in all its branches. Must be from 35 to 40 years of age, and sign an agreement for at least 3 years. Address by letter, O 26, *Journal Office*, Birmingham, enclosing references.

TO ENGINEERS.—Wanted, a Fitter; one used to erecting machinery. Must have a thorough knowledge of French language, as he will go abroad for a short time. Reference unexceptionable. Address, Clark and Co., 15Gate-street, Lincoln's Inn-fields, London.

SCRAP IRON.—Wanted, 10 to 15 tons per week of scraps, old boilers, or boats. Apply to Messrs. Gibbs Brothers, Deepfields Iron Works, near Bilston.

TO ENGINEERS, MILLWRIGHTS, MACHINISTS, &c.

VULCANIZED INDIA-RUBBER

In any of the following forms, of any size, or to Working Drawings for all MECHANICAL *purposes:—*

WASHERS for Steam and Gas Joints.	GAS-TUBING.	MACHINE AND MILL-BANDS fo Driving all kinds of Machinery.
VALVES for Marine and other Steam Engines.	SUCTION HOSE.	RAILWAY BUFFER SPRINGS.
ENGINE-PACKING (Elastic).	FIRE ENGINE AND FACTORY HOSE.	BALL VALVES.
PUMP-BUCKETS „	WATERPROOF CART, VAN, AND WAGGON COVERS.	PUMP-PACKING (Rings or Rope).
HOSE-PIPES.		WHEEL-TIRES (Noiseless).

N.B.—A Large Stock of the above always on hand, and any modification made to order.

Please address all communications to the Manufactory,

JAMES LYNE HANCOCK, VULCANIZED INDIA-RUBBER WORKS,

Goswell Road, London, E.C. (85)

HOBBS'S LOCKS.

The attention of Architects and Builders is respectfully invited to

HOBBS'S NEW MORTISE LOCKS,

Which are now manufactured by PATENT STEAM MACHINERY, and, while superior to any other locks in the market, are sold at a price which defies competition. The Plates are made of number "Twelve Gauge" Iron, and being so thick, the pins cannot be loosened by the constant jarring of the door. The security consists in four double-acting levers, while, to secure unusual freedom of motion and prevent the wear of the parts,

HOBBS'S PATENT FRICTIONLESS FOLLOWER

Is also applied. The retail price of these Locks is 10s., from which a liberal discount is allowed to the trade.

HOBBS'S NEW MORTISE LOCKING LATCHES FOR STREET DOORS,

Price 18s. And

HOBBS'S NIGHT LATCHES, RIM OR FLUSH, PRICE 10s.,

Are also recommended, together with every description of Lock required for house and cabinet work. Lists of Prices will be forwarded on application, post free.

N.B.—A complete Assortment of FIRE and BURGLAR-PROOF SAFES (Milner's Patent), fitted with HOBBS'S PATENT PROTECTOR LOCK, POWDER-PROOF.

ALSO, STRONG-ROOM DOORS, CASH AND DEED BOXES, ETC.

Address—Hobbs, Ashley, and Co., 76 Cheapside, E.C.

MANUFACTORY, ARLINGTON STREET, NEW NORTH ROAD. (98)

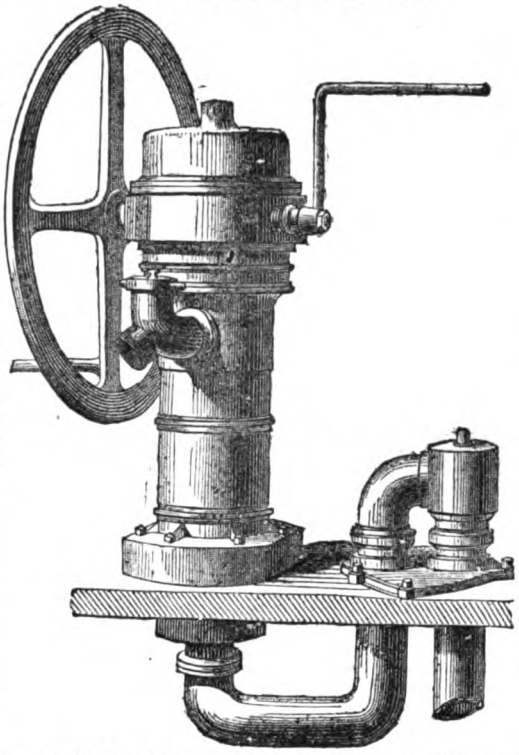
Under the Patronage of the Board of Admiralty.

SHIPS' PUMPS OF HER MAJESTY'S NAVY.

JOSIAH STONE,

Sole Manufacturer of DOWNTON'S well-known and much approved SHIPS' PUMPS, which have been used in preference to all others on board the vessels of Her Majesty's Navy, for upwards of thirty years, and have given the greatest satisfaction, effectually answering all the purposes required of any Ships' Pumps, and capable of throwing most powerful jets of water in case of fire.



These Pumps have also been most extensively used on board merchant vessels, both at home and abroad, and have been supplied to the Royal Navies of France, Prussia, Holland, Russia, Spain, and Turkey. The Pumps are portable, as they may be easily removed from the ship and put to work in a boat alongside in a few minutes. Each pump is fitted with a large foot valve plate (which may be placed in any part of the vessel most convenient), and from which communication is made to any number of distinct compartments in the vessel. In case of any of these pipes fouling, the water, by an almost momentary attachment, may be forced from the Pump downwards, so as to clear all obstructions, preventing any possibility of stoppage. The valves are of the simplest description, and being faced with ordinary leather discs, the latter may be renewed in a few minutes by the most inexperienced hands. By the peculiar construction of these Pumps, a most perfect and uninterrupted flow of water may be maintained; so uniform as to be undistinguishable from that proceeding from a cistern. The Pumps are made of several sizes, those of 7, 9, and 12 inches bore being most generally used. They may, however, be ordered of any dimensions required, and may be fitted either with one or two fly wheels. A standard, &c., is also supplied with these Pumps, to enable them, when necessary, to be used as ordinary hand-lever pumps.

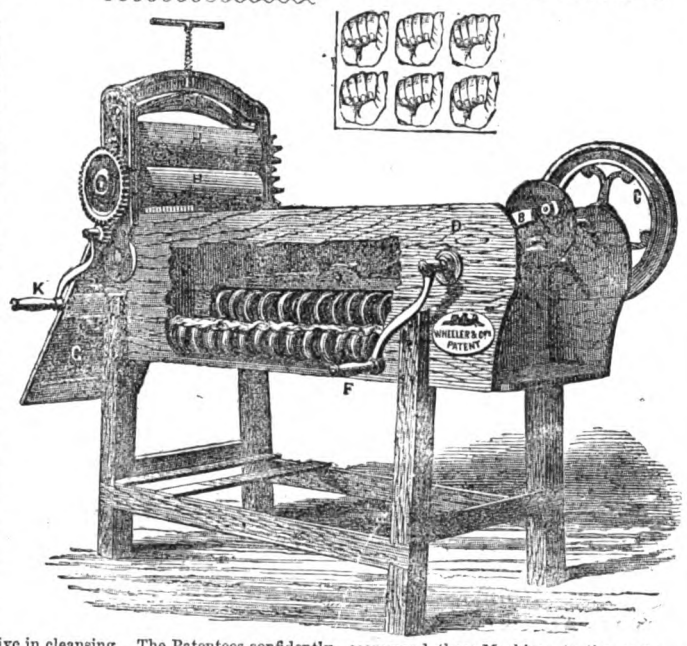
JOSIAH STONE, Engineer, Manufacturer of all descriptions of PUMPS and FIRE ENGINES for Land and Ships' Use; Brass and Iron Founder and Finisher, Nail and Rivet Maker, &c.

CONTRACTORS FOR FIRE-ENGINES, ETC., TO THE WAR DEPARTMENT,

RAILWAY STATION, DEPTFORD, AND 12 GARLICK HILL, CITY, E.C.

(97)

T. WHEELER AND CO.'S
"OXONIAN KNUCKLE WASHING MACHINE."



THE Improvements in these New Inventions are the non-exposure of the user's hands to the dangerous parts of the Machine, and the rapidity with which the work is done. These Machines have neither bands or wheels passing on the outside, wherein lies the liability to accident. The rubbers are the truest representation of the knuckles or hand washing yet brought out; the compensating floating rubbers work at right angles, backward and forward, in the same manner as does the hands. These Machines can be supplied with rubbers that represent a person's hand in the action of rubbing; the knuckles, finger nails, and palm of the hand being truly modelled. They are capable of Washing Clothes of every description whatsoever, the largest bedding to the most delicate piece of muslin can be washed without breaking a single thread; in fact, such is the delicacy of the action of these Machines, that the paper you are now reading can be passed between the rubbers without sustaining any injury, at the same time being thoroughly effective in cleansing. The Patentees confidently recommend these Machines to the notice of Laundresses, Heads of Families, Hotels, Emigrants, &c. So simple is the action of this Machine, that a boy or girl of 10 or 12 years of age can work it; the only skill required is to soak the clothes one hour before placing them in the Machine, placing a portion of the clothes at the handle end of the Machine; laying on the rubbers a part of them; turn the handle, and the clothes will pass through between the rubbers to the opposite end, effecting a saving of at least 50 per cent.

Prices: Washing Machines, £1 6s., £2 6s., £3 6s., £4 10s., £5 15s.; Washing, Wringing, and Mangling, £8 £10 15s., £14 14s.—Full Instructions sent with every Machine. Testimonials or References sent on application.

MANUFACTORY, ALBION WORKS, PARK END STREET, OXFORD (114)

TO BRASS-FOUNDERS, ENGINEERS, &c.

THE PATENT PLUMBAGO CRUCIBLE COMPANY having completed the enlargement of their premises, beg to call the attention of all users and shippers of Melting Pots to the great superiority of the PATENT CRUCIBLES, which have been used during the last three years by some of the largest melters in England and abroad. In addition to their capabilities of melting an average of from thirty-five to forty pourings; they are unaffected by change of temperature, never crack, but can be used till worn out, requiring only one annealing for several days' work, and become heated much more rapidly than ordinary pots, effecting thereby a saving of more than fifty per cent. in time, labour, fuel, and waste. The Patent Plumbago Crucible Company also manufacture and import clay crucibles, muffles, portable furnaces, sublimate pans and covers, glass-pots, all descriptions of fire- standing goods, and every requisite for the assayer and dentists. For Lists, Testimonials, &c., apply to Battersea Works, London, &c. (43

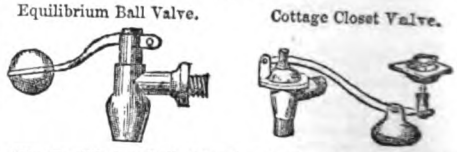
PUMPS
FOWLER & Co.
WHITEFRIARS STREET,
FLEET STREET,
— LONDON. —

HYDRAULIC MACHINERY OF EVERY DESCRIPTION, FOR HOME USE OR EXPORT, UPON THE LARGEST, OR SMALLEST SCALE. MANUFACTURED, FIXED, OR LENT ON HIRE: AN EXTENSIVE STOCK KEPT READY FOR GENERAL PURPOSES.

(108)

HIGH-PRESSURE VALVE-COCKS,
LAMBERT'S PATENT.

Equilibrium Ball Valve. Cottage Closet Valve.



The Equilibrium Ball-Valve is simple and certain in its action, and is cheaper than the common cocks now in use.

The Cottage Valves are suitable for application to any kind of basin; and, as they shut against the pressure, no concussion in the pipes can possibly occur.

These cocks have been extensively and most successfully used in many towns, under continuous high pressure, varying from 100 to 350 feet; their efficiency and durability is, by experience, established.

THOMAS LAMBERT and SON,

Brass Founders, Short-street, New-cut, Lambeth.

(36)

PUMPING MACHINERY.

GWYNNE AND Co., Engineers, London, manufacture and supply the following Machinery, of the most approved construction and with all the latest improvements:—Portable and Fixed Steam-Engines and Boilers of every description; Waterwheels, Windmills, Horse and Hand-power Machines; Pumping Machinery for the Supply of Towns, Cities, and Districts, and for the Irrigation of Coffee, Cotton, Indigo, Sugar-cane, and Rice Estates, for pumping out Coffer-dams, Canals, Dry Docks, Reservoirs, &c. They also manufacture and supply the Pumping and other Machinery for Paper, Pulp, and Fulling Mills, Breweries, Distilleries, Tanneries, Starch Works, Bleaching, Dyeing, and Calico Printing Works, Chemical Works, Silk, Cotton, and Flax Mills, and Manufactories in general. All Letters not paid will be refused. Illustrated Price Lists forwarded on receipt of Six Postage Stamps.—GWYNNE AND Co., Hydraulic and Mechanical Engineers, Essex-wharf, Strand, London.

For Exportation.—The above can be obtained through British Merchants, Shippers, and Colonial Agents. (24)

CLAYTON, SHUTTLEWORTH, AND CO.,

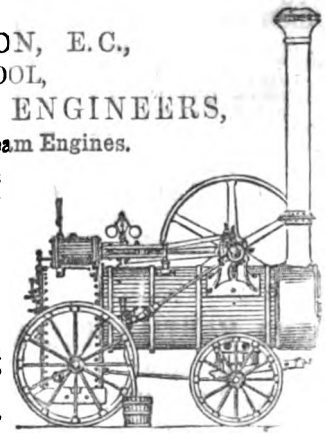
OF LINCOLN,

78 LOMBARD STREET, LONDON, E.C.,

AND 36 DALE STREET, LIVERPOOL,

AGRICULTURAL AND GENERAL ENGINEERS,

And Manufacturers of Portable and Fixed Steam Engines.



Combined Threshing Machines, which dress the corn ready for market at one operation. Grinding Mills, Saw Benches, Pumps for Irrigation and Mining purposes, with all necessary gearing for being driven by steam power. Full particulars and estimates given on application to the above address.

C. S. and Co.'s PORTABLE STEAM ENGINES are adapted for every purpose to which steam-power can be applied. When intended for winding, they are fitted with reversible link motion and winding gear. They are easy of removal, as may be seen by the engraving, and can be set to work immediately on arrival.

C. S. and Co. are now doing an extensive foreign and colonial business, and are prepared to send off engines and machinery of the before-mentioned kinds in a few days from the date of order. They would also call attention to the important *reduction in prices* made for the new year.

For Exportation.---The above can be obtained through British Merchants, Shippers, and Colonial Agents. (23)

IMPROVED MACHINERY FOR AGRICULTURISTS.

RICHARD GARRETT & SONS,

LEISTON WORKS, SAXMUNDHAM, SUFFOLK,

(ESTABLISHED A.D. 1778),

EARNESTLY solicit the continued support of their numerous Friends, Agriculturists, Shippers, and others; the additions made to their Works during the present year, in the erection of new sets of Workshops, fitted with the best mechanical appliances for producing Machinery of the most improved construction, expeditiously and economically, justifies their soliciting increased support, while their leading reputation as Inventors and Manufacturers of FIRST CLASS Agricultural Machinery, is a sufficient guarantee that every Machine supplied from Leiston Works will prove to the entire satisfaction of the purchaser.

R. G. & S. are now manufacturing the following Machines and Implements, which they guarantee to be thoroughly efficient in every respect :—

PORTABLE AND FIXED STEAM ENGINES. } From 4 to 40 Horse Power, suited for every kind of work
SELF-PROPELLING AND TRACTION ENGINES. } to which Steam Power is applied.
STONE GRINDING MILLS.
MORTAR AND PUG MILLS.
MILLWRIGHTS' WORK of all kinds.
SAWING MACHINERY, from 4 to 20 Horse Power.
BRICK AND TILE MACHINES.

IMPROVED SETS OF FARM MACHINERY, for Large Occupations.
PORTABLE AND FIXED MACHINERY, for Thrashing and Dressing Corn.
THE PRIZE BOLTING AND OPEN-DRUM HORSE-POWER THRASHING MACHINES.
CORN DRESSING MACHINES, for Hand, Horse, Water, and Steam Power.
BARLEY AVELLING MACHINES.
CHAFF CUTTERS, for Hand, Horse, Water, and Steam Power.
PATENT TURNIP CUTTING AND PULPING MACHINES.

THE PRIZE CORN AND SEED DRILLS.
PRIZE CORN AND SEED DRILLS WITH MANURE APPARATUS.
PRIZE SEED AND MANURE DRILLS.
LIQUID, SEED, AND MANURE DROP DRILLS.
CHAMBER'S PATENT BROADCAST MANURE DISTRIBUTOR.
GARRETT'S PATENT HORSE HOE for all Crops.
PATENT REVOLVING HOES for Root Crops.
IMPROVED PLOUGHS AND REAPING MACHINES.
&c. &c. &c.

Of which full detailed particulars will be found in R. G. & SONS' ILLUSTRATED CATALOGUE, sent postage free to any address, in English, French, or German; and any of the above Machines will be shown in operation at R. G. & Sons' Farm, near the Works, on their receiving a few days' notice.

A Copy of R. G. & SONS' new COLONIAL LIST will be forwarded free to any of the Colonies, and Shippers will be supplied with these lists, with their names and addresses printed on, free of charge, by making application for the same.

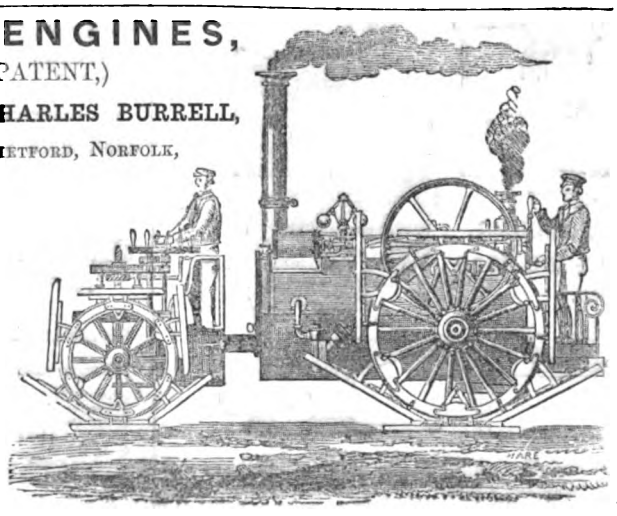
ADDRESS—R. GARRETT & SONS, LEISTON WORKS, SAXMUNDHAM, SUFFOLK. (57)

TRACTION ENGINES,

(BOYDELL'S PATENT,)

MANUFACTURED BY CHARLES BURRELL,

ST. NICHOLAS WORKS, THETFORD, NORFOLK,



And ordered for India, Australia, and South America, may now be seen, complete and in course of construction at the above works. BOYDELL'S TRACTION ENGINES AND ENDLESS RAILWAY will draw heavier loads over good roads than any other traction engine, and on soft and bad roads will draw heavy loads where no other traction engine can move itself. All objection to the wear and tear of these Engines is entirely removed by the use of Charles Burrell's improved patent Wrought Iron Wheels, fitted with Rails and Tyre, as well as all the wearing parts, of Steel.

Apply also to Mr. Hemming, 47 Mark Lane, E.C.

(40.)

CAUTION.

TO ARCHITECTS AND BUILDERS.—In consequence of numerous complaints, the Patentee begs to inform the above, that all genuine

SMITH'S PATENT DOOR SPRINGS,

For Swing Doors, are stamped with Name and Address, thus—

SMITH, PATENTEE, 69 PRINCES STREET, LEICESTER SQUARE, LONDON,

and that Springs thus marked are warranted.

SMITH'S PATENT WEATHER-TIGHT CASEMENT FASTENING AND SILL-BARS

are admitted by all to be the most perfect invention for the purpose. Diagrams and List of Prices on application. (143)

HALKETT'S GUIDEWAY STEAM AGRICULTURE will be Exhibited at Canning-place, Kensington Toll Gate, South of Kensington Gardens, on Wednesdays, the 9th, 16th, and 23rd of February, and to private view upon previous appointment. By this system, every operation of the Farm is performed by Steam Power, the land largely increased in value, and the cost of cultivation greatly reduced. A paper read before the Society of Arts, illustrations, &c., will be forwarded upon application to the Office, 80 Chancery-lane, W.C. (101)

WATER GAUGES—WATER GAUGES.—Sir,—We find your German Gauge Tube superior to any other, and strongly recommend it. We were compelled to abandon the use of our water gauge until applying your glass tube.

WILCOX and Co., Millwall Pottery Company.

These Tubes are superior to all others; being a clear white, no mistake can arise in working. Guaranteed to stand a pressure of 500 lb.

Extensively used on all the principal lines.

To be had only of E. MOORE, 55 Upper Marylebone-street, W.; and 72 Great Titchfield-street, W.

*** Price List of Gauge Fittings, &c., on application. (98)

TO WIRE ROPE MAKERS.—ARCHIBALD SMITH is now prepared to GRANT LICENCES for the use of his PATENT ROPE MACHINERY, guaranteed to work at six times the speed of any other, and to save upwards of fifty per cent. in the cost of making. It is used by the most eminent makers, and was also in the manufacture of the Atlantic Cable.—Apply to 69 Princes-street, Leicester-square, W. (8)

THE GENERAL IMPLEMENT CO.,

36 BOTHWELL STREET,

GLASGOW.

Agricultural Implements of all kinds.

MOWING & REAPING MACHINES.

Price Lists free on application.

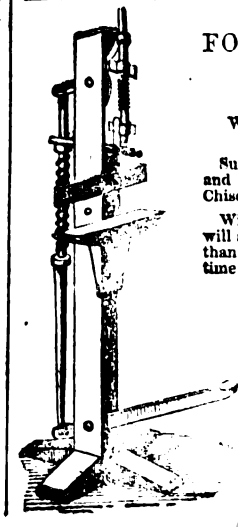
AGENTS WANTED. (32)

ARTESIAN WELLS, BORING TOOLS, PUMPS, &c. Engineers, Architects, Surveyors, Builders or others requiring a good supply of Water may have any quantity procured by W. SPELLER, 14 York-street, Blackfriars'-road, London, where may be had any quantity of Tools for Sinking or Boring, from 2 to 20 inches diameter, and from 100 to 2,000 feet depth; also Men and Tools to bore for Railroads, Minerals, &c., in any part of the world. Boring Tools and suitable Pipes for exportation, with full instructions for their use.

Builders, Contractors, Brickmakers, Barge and Ship Builders, and others, can be supplied with Wrought or Cast Iron Pumps, Double or Single, for excavation of Deep Wells, from 3 to 14 inches in the bore, and from 6 to 130 feet in length, to work by Hand or Steam Power.

Hot-water Apparatus for Conservatories, &c., on the most economical and improved principles.

Also Manufactory for Captain John Grant's much improved Cooking Apparatus. (14)



FOOT MORTISING MACHINES,

With set of Chisels, for £9.

Superior to any in use for Doors and Sashes, with self-reversing Chisel.

With this Machine the workman will acomplish one-third more work than with any other in use, as no time is lost in shifting the Chisel.

For Sale by

L. D. OWEN & CO.,

Importers of

WOOD-WORKING MACHINES,

192 Tottenham-court-road

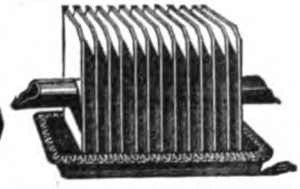
PIERCE'S
UNRIVALLED
PYRO-PNEUMATIC FIRE-LUMP WARMING AND VENTILATING STOVE GRATES,

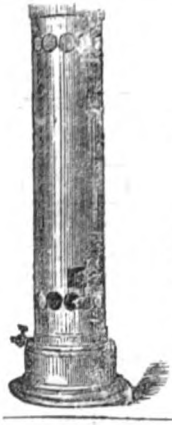
WITH the cheerful, open fire, producing healthful warmth, with continuous Self-acting Ventilation, for Churches, Schools, Public Buildings, Banking Houses, &c. These Grates are manufactured solely by PIERCE, the Inventor, for which he received the Prize Medals of London in 1851, and of Paris in 1855.
PRICE, from £7 10s.
ILLUSTRATED CATALOGUE, with Prices and Estimates for Work, furnished on application to the Inventor and Sole Manufacturer.
Also his
IMPROVED COTTAGER'S GRATE,
For Warming Two Rooms with only One Fire. Prices, 30s. and 35s.
PIERCE, No. 5 JERMYN STREET, REGENT STREET.
(111)

THE LONDON
WARMING AND VENTILATING COMPANY,
(LIMITED,)
36 GREAT GEORGE STREET, Westminster, S.W.
(MANAGER—Mr. WOODCOCK.)

Churches, Greenhouses, Offices, and Buildings of every description warmed by means of a modification of the plan successfully used during the last five years by Mr. Goldsworthy Gurney in both Houses of Parliament.
Steam, Hot-water, Gas, and in open or enclosed fireplaces, Coal and Coke are equally available for the process.
The cost is less and the effect greater than that of any other known means.



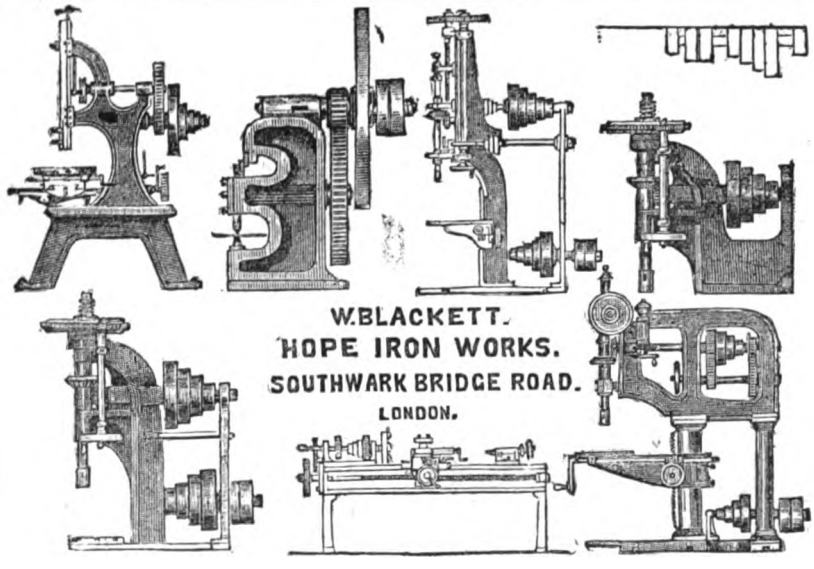
The Horticulturist will find herein an instrument of new and important powers.
The apparatus may be seen in ST. PAUL'S CATHEDRAL, the various offices of the "Department of Science and Art," and in many churches and other buildings.
Particulars and Testimonials forwarded on application.
(12)



VENTILATION WITHOUT FLUES.
KUKLA'S PATENT STOVES,
At 18s., 25s., and 50s.

KUKLA'S newly-invented Deflagrator—the first and only perfect GAS STOVE. Guaranteed to burn without flue—without dust, smell, or smoke, producing a great and pure heat with the least expenditure of Gas.—*Vide Society of Arts' Journal.*
Patronised by the English and French Government.
Scientific in Principle,
Simple in Construction,
Healthy and efficient in use.

The Deflagrator Stove is cheap, portable, and suited for every situation; and from the principle on which it is constructed (viz., expanding to a sixfold volume the gas used) is capable of warming any given space more quickly and more thoroughly than any other means: while its addition forms a sure remedy for any ill-warmed or ill-ventilated apartments.
The 25s. Deflagrator warms a room of 2,000 cubic feet at a cost of 3d. per day.
The 50s. Deflagrator warms 5 to 6,000 cubic feet at a cost of 6d. per day (twelve hours).
Also, the Greenhouse Stove at 18s.
Patentee and sole Manufacturer, F. X. KUKLA, 194 Pentonville-road, London.
Country orders promptly attended to. Carriage free to any Railway in London.
Post-office Orders should be made payable to FRANCIS XAVIER KUKLA, General Office.
N.B.—Every Stove separately tested before sent out.
The New Gas COOKING STOVE for 10 persons, price £3. (103)



W. BLACKETT has in Stock a variety of Vertical and Horizontal Steam Engines, Boilers, and Engineers' Tools, ready for delivery on the shortest notice. Apply as above. (70)

IMPORTANT TO MANUFACTURERS, MILL OWNERS, &c.

GUTTA PERCHA MILL BANDS.

THE GUTTA PERCHA COMPANY beg to state that the increasing demand for the Gutta Percha Strapping for Driving-bands, Lathe-straps, &c., fully justifies the strong recommendations they have everywhere received.
Their durability and strength—permanent contractability and uniformity of substance—their non-susceptibility of injury from contact with oils, grease, acids, alkalies, or water—and the facility with which the only joint required can be made in bands of from 200 to 300 feet long—render them superior to leather for almost all working purposes, and decidedly more economical.

TESTIMONIALS.
IMPORTANT ANNUAL SAVING.

From TRUMAN, HANBURY, BUXTON, & Co., Brewery, London.

"In reply to your inquiry, we have much pleasure in bearing our testimony to the advantages, both as regards economy and saving of time, effected by the use of your Patent Gutta Percha Bands in lieu of Leather Straps. The stoppage of one portion of our works through the failing of the leather strap used to be of daily occurrence—but with this annoyance we are now never troubled. We have had these straps in operation for nearly three years, and are assured by our Engineer that *they effect a saving to us of at least* THIRTY POUNDS *a year.*"

From JAMES ABERNETHY & Co., Fury Hill Foundry Aberdeen.

"We have now had Gutta Percha Bands working here *for three years.* One of them has been driving the fan blast for our smith's shop for all that time, and for anything we see, may drive it as long again. The speed of the fan is but 1,200 per minute. We have used them with complete satisfaction, driving circular saws, and in some cases where leather bands would have been quite inapplicable from damp. We have uniformly endeavoured to have the drums and pulleys so proportioned to the strain, as that there is no chance of the band slipping; and with this precaution, and taking care in using *cross bands that they do not rub*, we are quite satisfied that they are superior in every respect to leather—stronger at the same weight, and keeping quite straight in working—requiring no lacings, and very seldom any repairs."

WATER POISONED BY LEADEN PIPES.

The above engraving represents accurately a section of a leaden pipe, which was employed for a short time in conveying water from a well on the grounds of Mr. Dick, of Bonchurch, Isle of Wight.

POISONED WATER PREVENTABLE
BY THE USE OF GUTTA PERCHA TUBING.

The Gutta Percha Company have been favoured with the following letter,

From Dr. MURRAY, Hull.

"It is impossible to conceive of anything more injurious or destructive to the health of the community than the use of *leaden pipes* for the conveyance of water. The poisonous salts of lead thereby communicated are most insidious and subtle. I hail with gratitude the substitution of Gutta Percha Tubing. I have had the leaden pipe of my own house removed, and its place supplied with one of Gutta Percha Tubing. Nothing can be better. I have also recommended it to others, who have adopted the expedient."

A variety of Gutta Percha Articles, such as Mill Bands, Tubing, Sheet, Soles, Pump Buckets, Bosses, Union Joints, Bottles, Bowls, Flasks, Curtain and Cornice Rings, Solid Frames, Galvanic Batteries, &c., &c.

MANUFACTURED BY THE
Gutta Percha Company, Patentees,
18 WHARF ROAD, CITY ROAD, LONDON,
AND SOLD BY THEIR
WHOLESALE DEALERS IN TOWN AND COUNTRY.

TO BRASS FOUNDERS.

TO BE SOLD, the Patent-right of a New and Highly-approved EQUILIBRIUM WATER COCK or VALVE, suitable for Steam Boiler Feed Pipes, or any cases where the valve is required to be opened against pressure.

Address H., MECHANICS' MAGAZINE Office, 166 Fleet-st., where a Drawing may be seen. (151)

TO ENGINEERS, MILLOWNERS, AND MANUFACTURERS.

AMERICAN INDIA-RUBBER Machine Belting, Valves and Washers, Brewers' Hose, Fire Engine Hose, Improved Suction Hose—at Wholesale Prices.

W. T. HENDRY & CO.,
38 Upper Thames-street, London, E.C. (152)

FOG WHISTLES, for Seagoing Steamers.
WATER GAUGE MOUNTINGS, for Marine and Land Boilers.
GAUGE COCKS, GLAND COCKS, GREASE COCKS, CUPS and SYPHONS.
STEAM TAPS, RANGE COCKS, &c.
IMPROVED BRASS VALVES, for Steam, Water, and Gas.

W. T. HENDRY & Co., Engineers.
38 Upper Thames-street, London, E. C. (153)

ENGINEERING AND MECHANICAL DRAWING CLASSES.—Instruction given in Engineering and Mechanical Drawing, comprising the preparation of plans, elevations, and sections of marine and locomotive engines, with the detail and working drawings; also the method of delineating screws, bevel wheels, &c.; orthographical projection, and tinting, shading, and colouring taught.—For prospectuses of the Day and Evening Classes apply to Mr. T. J. HILL, at the offices, 15, Old-street, City-road. (73)

TO MARINE ENGINEERS, OR SHIP-BUILDERS.

THE PROPRIETOR of a VALUABLE PATENT for Double-expansive Marine Engines (by which great economy of space and fuel is obtained) is desirous of entering into arrangements with a respectable firm for the construction of the same. An adequate portion of the patent-right would be assigned by the advertiser to any firm taking the matter up; and he would render all assistance in his power, either in London or elsewhere, amongst ship-owners (to many of whom he is well known), in obtaining contracts, &c. Unexceptionable references given. Address C. E., MECHANICS' MAGAZINE Office, 166, Fleet-street. (76

HART & SON, MALLEABLE IRON-FOUNDERS, 4 Vine-street, York-road, Lambeth. Orders for Malleable Iron Castings executed within a week. (77)

INDIA-RUBBER VALVES FOR STEAM ENGINES, PUMP PACKING, &c.—Explanatory Drawings and Information as to the best modes of fitting and arranging the above, and all other Mechanical Applications of VULCANISED INDIA-RUBBER, are furnished post-free by

CHARLES MACINTOSH & Co., Patentees,
Cambridge-st., Manchester, and 3 Cannon-st. West, London.
MANUFACTORY and DEPÔT, Cambridge-st., Manchester.
GENERAL WAREHOUSE, 3 Cannon-street West, London, E.C.—C. M. and Co.'s only Establishments. (139)

STEAM ENGINES FOR SALE.

PORTABLE STEAM ENGINES, from 6 to 12 horse power,
STATIONARY STEAM ENGINES, from 4 to 50 horse power,
TUBULAR BOILERS, from 4 to 50 horse power,
CORNISH BOILERS, from 4 to 50 horse power,

Are in hand, and can be despatched on eight days' notice. Prices moderate. Workmanship and Material of the best description.

Apply to R. THORNTON & Co., St. Leonard's Iron Works, Edinburgh. (60)

GLADSTONE & Co., CONTRACTORS and ENGINEERS.
2 John-Street, Minories, London, E.C.,

Are prepared to ESTIMATE FOR and CONSTRUCT BRIDGES, PIERS, JETTIES, &c., in Iron, Wood, or Stone. Also to supply Cranes, Girders, Turntables, and Railway Work and Plant generally. (56)

CHUBB'S LOCKS, FIREPROOF SAFES, CASH AND DEED BOXES.
Complete lists of sizes and prices may be had on application.

CHUBB AND SON,
57 ST. PAUL'S CHURCHYARD, LONDON;
28 Lord-street, Liverpool; 16 Market-place, Manchester, and Wolverhampton. (4)

BRICKS.

TO BE LET, with immediate possession, in consequence of the death of the proprietor, J. M. Paine, the DIPPENHALL SILICA FACTORY, erected for the purpose of making improved Fire Bricks, Building Bricks, Paving Tiles, &c., &c., from the Soluble Silica Rock.

Apply to view the Buildings and Bricks to G. H. Ogston, Esq., Resident Manager, Dippenhall, Farnham, Surrey; and for terms, to Messrs. Nicholls and Potter, Solicitors, Farnham. (125)

TO ENGINEERS, ARCHITECTS, PATENT AGENTS, &c.

PHOTOGRAPHS OF THE HIGHEST CLASS and of any size, taken and reproduced at a most moderate rate of charge. Reproductions of faultless accuracy, of Machinery, Models, Drawings, &c. Orders attended to in town and country. Estimates forwarded.
SPENCER, READ, & Co., 4 Agar-street, Strand. W.C. (90)

FIRE BRICKS.—THE FARNHAM INDESTRUCTIBLE SILICIOUS FIRE BRICKS have been greatly REDUCED in PRICE, and will be delivered at the Nine Elms Station, London, at 90s. per 1,000.—Address, G. H. OGSTON, J. M., Paine's Silica Works, Farnham, Surrey. (35)

VITRIFIED BLUE BRICKS are delivered at the Nine Elms Station, London, at 80s. per 1,000.—Address, G. H. OGSTON, J. M. Paine's Silica Works, Farnham, Surrey. (36)

MATHEMATICAL DRAWING INSTRUMENTS, RULES, TAPES, CHAINS, LEVELS, THEODOLITES, BOX SEXTANTS, PRISMATIC and POCKET COMPASSES. Price Lists of the above articles sent post free, by JOHN ARCHBUTT, 20 Westminster Bridge Road, Lambeth, near Astley's Theatre. Every article warranted, and the prices will be found considerably lower than ever before charged for articles of similar quality. Routledge's Engineers' Slide Rules, 4s. 6d. each; Hawthorn's ditto, 5s. 6d.; Carpenters' Rules from 1s. (118)

EDWIN JEWITT, ENGRAVER ON WOOD AND DRAFTSMAN, 1 Pickett-place, Strand, near Temple-bar. Engineering, Scientific, and Mechanical Designs accurately engraved. Manufacturers and Tradesmen's Catalogues Illustrated. W.C. (84)

TO CARD CASE MAKERS.

WANTED a Good Workman in the Card Case and Pencil and Brush Case Trades, to undertake a large quantity of work of a similar character.—Apply to W. W., MECHANICS' MAGAZINE Office, 166 Fleet Street. (131)

TO ENGINEERS, INVENTORS, AND OTHERS.

A PRACTICAL ENGINEER of long standing prepares Original Drawings, Copies, and Tracings. Advice and Assistance given to Inventors in working out their Plans. Pupils taught privately. Terms moderate.
Apply to J. J., 171 Strand. (138)

The London Cork Company (Limited).—Machinery, Patents, Engine, Boiler, Fixtures, &c.

MR. R. KEYSELL has received instructions to SELL by AUCTION, on the Premises, 17 Mason-street, Westminster-bridge-road, on Wednesday, Feb. 23, at Twelve, the whole of the MACHINERY of the above Company: comprising Squaring, Rounding, and Bung Machines, Shafting, Riggers, Driving Straps, 12-Horse Power Condensing Beam Engine (by Blythe), 12-Horse Power Boiler, Cork Bins, &c.; also the Furniture and Fittings of Counting-house and Board-room, Gas-Fittings, &c., and every requisite for carrying on the business on a scale of magnitude, together with the English, Irish, and Scotch Patents. May be viewed two days preceding the Sale, when the Machinery will be set in motion, and every explanation given; and particulars had of W. Greatorex, Esq., Solicitor, 59 Chancery-lane; of Messrs. Thorndike and Smith, 11 Staple-inn, Holborn; on the Premises; and of Mr. R. Keysell, Auctioneer, 91 Fleet-street. (150)

STEAM ENGINES.

FOR SALE, a superior HIGH PRESSURE HORIZONTAL STEAM ENGINE of 6-horse power, 8-inch cylinder, and 1-foot 6-inch stroke. One of 8-horse power, 10-inch cylinder, and 1-foot 6-inch stroke. One of 10-horse power, 12-inch cylinder, and 2-feet stroke. Two of 14-horse power, 14-inch cylinders, and 2-feet stroke; and one of 30-horse power, 20-inch cylinder, and 3-feet stroke.

Apply to Messrs. PAGE and CAMERON, 64 Old Broad Street, E. C., London. (124)

ENGINEERING BUSINESS FOR SALE.

OWING to the continued ill health of the Proprietor, the first-class business of an Engineer and Crane and Block Maker is offered for sale. It has been established in the Metropolis for nearly 30 years, and has enjoyed extensive patronage amongst Brewers, Manufacturers, Warehousemen, and others, in and about London; the business done amounting to nearly £8,000 per annum. About £3,200 would be required, (part of which, however, may remain for any reasonable time on good security,) which is the bare value of the tools, patterns, and stock in trade. The premises, including good dwelling-house, very conveniently situated, and capable of accommodating from 60 to 70 hands, are held upon a long lease, at an extraordinary low rental, not exceeding £100 per annum, taxes included. Many of the tools are nearly new, and of the best construction. The present proprietor, who relinquishes the business solely on account of ill health, would give every assistance in his power to those succeeding him; and as his foreman, who has been with him for nearly ten years, is thoroughly acquainted with the practical parts of the business, any gentleman desirous of commencing as a manufacturing engineer would find the present a very favourable opportunity. As all accounts have been, for many years past, collected quarterly, a very small amount, say £800, would suffice as working capital. Full particulars may be obtained by application to E. E. ALLEN, Esq., MECHANICS' MAGAZINE Office, 166 Fleet Street, E.C. (139)

TO ENGINEERS' TOOL MAKERS, AND OTHERS.

THE ADVERTISER is desirous of meeting with an engagement as TOWN or DISTRICT AGENT for an Engineers' Tool Maker, or firm whose business lies amongst Engineers and practical men. He is an Engineer by profession, has for many years been engaged in bringing into operation several inventions, and can give unexceptionable references. A very moderate fixed salary only expected. Address M. C., MECHANICS' MAGAZINE Office, 166 Fleet-street. (78

ENGINEERS' TOOLS.

FOR SALE, a Self-acting Slide LATHE, 11-inch Centres, and Bed 12 feet long, complete; and TWO PORTABLE PUNCHING and CUTTING MACHINES, one suitable for ½-inch plates, and the other for ¾-inch plates, both adapted for steam or hand power.

Apply to Messrs. PAGE & CAMERON, 64 Old Broad Street, E.C. (117)

Digitized by Google

TO STEAM SHIP OWNERS, ENGINEERS, AND OTHERS.

How's Patent Steam Engine Counters, can be read at sight.

These Counters register the number of revolutions made by an engine or other mechanism. They may be used for ascertaining the duty of Pumping Engines and Water-wheels; the revolutions on board a steam-vessel; to calculate the slip of the propeller; and in a locomotive to test the slip of the wheels.

How's Patent Salinometer, for Steam Boilers using Salt Water.

By these, the density of the water in the Boiler is at all times accurately shown, and a saving of boiler and fuel is effected. They are adopted by the Admiralty, the Honorable Trinity Corporation, and others. Copies of Testimonials from Messrs. Penn, Messrs. Maudslay, and others, will be forwarded on application.

How's Engine-Room Telegraph, for communicating between Captain and Engineer.

Society of Arts Prize Medal, 1855.

This is a Mechanical Telegraph, and by its peculiar construction, error or misunderstanding is rendered impossible. It is now extensively adopted, and gives great satisfaction.

How's Patent Fresh Water Apparatus for Ships' Use.

This apparatus is designed for the distillation of Fresh from Salt Water; and on long voyages, and where the supply of water is scanty, it will be found invaluable. Testimonials may be seen.

Patent Steam Pump and Fire-Engine for Ships' Use.

This Steam-pump occupies but a small space; works perfectly noiselessly, and throws an immense volume of water. An Illustrated Circular of Fresh Water Apparatus and Steam-pump combined, free on application.

How's Patent Machine for Cutting Bolts, Rods, Spindles, Wire, &c.

Simple in construction, inexpensive, occupies but little space, and will not easily get out of order.

A Pamphlet Illustrative of the above, sent free by post, on application to

A. P. HOW, ENGINEER,

81 MARK LANE, LONDON.

EVERY DESCRIPTION OF ENGINEERS' TOOLS, ENGINE ROOM STORES, &c., &c., SUPPLIED.

(89)

SCOTT'S
PATENT GRASS SEED SEPARATOR,

which entirely extracts the Seeds of "COUCH," "TWITCH," "SPEAR," or "HAIR" GRASS, and other impurities from

PERENNIAL AND ITALIAN RYE-GRASS, &c.,

AND

SCOTT'S PATENT CARROT SEED BEARDING

AND

CLOVER AND TREFOIL MILLING OR DRAWING MACHINE,

which effectually removes the beard from Carrot Seed, rendering it fit for sowing with facility by drill or otherwise, and by the separation of abortive or diseased grains vastly increases its vegetative per centage. By a slight modification it is applicable to the other purposes before mentioned.

These Machines were admittedly the most novel, and, at the same time, the most useful and important to the Farmer of any exhibited at the late SMITHFIELD CLUB SHOW.

They may be seen at work at the Establishment of the Manufacturer,

Mr. T. MIDDLETON, Engineer, Southwark.

Communications to be sent to the Patentee, J. SCOTT, 111 Drummond Street, Euston Square, London, N.W.

(48.)

HOBBS'S LOCKS.

The attention of Architects and Builders is respectfully invited to

HOBBS'S NEW MORTISE LOCKS,

Which are now manufactured by PATENT STEAM MACHINERY, and, while superior to any other locks in the market, are sold at a price which defies competition. The Plates are made of number "Twelve Gauge" Iron, and being so thick, the pins cannot be loosened by the constant jarring of the door. The security consists in four double-acting levers, while, to secure unusual freedom of motion and prevent the wear of the parts,

HOBBS'S PATENT FRICTIONLESS FOLLOWER

Is also applied. The retail price of these Locks is 10s., from which a liberal discount is allowed to the trade

HOBBS'S NEW MORTISE LOCKING LATCHES FOR STREET DOORS,

Price 18s. And

HOBBS'S NIGHT LATCHES, RIM OR FLUSH, PRICE 10s.,

Are also recommended, together with every description of Lock required for house and cabinet work. Lists of Prices will be forwarded on application, post free.

N.B.—A complete Assortment of FIRE and BURGLAR-PROOF SAFES (Milner's Patent), fitted with HOBBS'S PATENT PROTECTOR LOCK, POWDER-PROOF.

ALSO, STRONG-ROOM DOORS, CASH AND DEED BOXES, ETC.

Address—Hobbs, Ashley, and Co., 76 Cheapside, E.C.

MANUFACTORY, ARLINGTON STREET, NEW NORTH ROAD. (86)

By Her Majesty's Royal Letters Patent.

RANSOME'S PATENT IMPERISHABLE SILICIOUS STONE.—Chimneypieces, Balustrades, Capitals, Trusses, Terminals, Fountains, and Vases; also, Enamelled Stone Chimneypieces, of great beauty and novelty, at reduced prices. Monumental or Mural Memorials, Grave Stones, Space Markers, and Indicators for Cemeteries, &c., of every description, at the lowest price.

RANSOME'S PATENTED PROCESS FOR PRESERVING STONE.—Invaluable in its application to Public Edifices and Private Residences. By this process the softest and most friable stone can be rendered impervious and imperishable, and decay at once arrested and prevented.

RANSOME'S PATENT STONE FILTERS FILTERING SLABS.—Manufactured for every Private or Domestic purpose, for Manufactories, Public Companies, Shipping, &c. Several hundred thousand gallons of water are filtered daily by Ransome's Patent Stone Filtering Slabs, for the town of Southampton. They have also been adopted by the Admiralty, the Board of Ordnance, the Colonial Land and Emigration Commissioners, and other Public Bodies for several years; also in the City of Rotterdam, with the most perfect success.

For particulars, specimens, illustrations, and agencies, apply to

Mr. FREDERICK RANSOME,

WHITEHALL WHARF, CANNON ROW, WESTMINSTER;

OR PATENT STONE WORKS, IPSWICH.

A liberal discount allowed to the Trade or to Shippers.

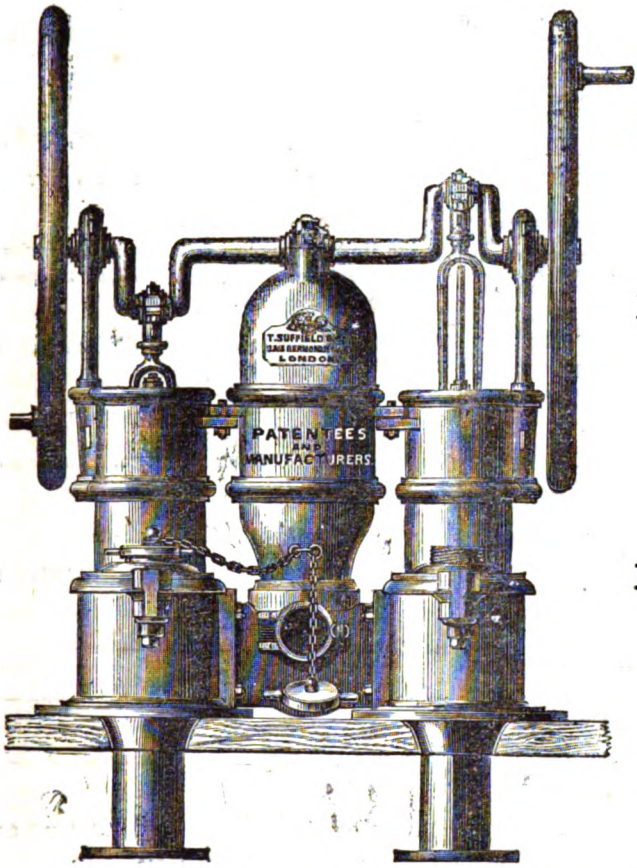
T. SUFFIELD AND CO.

Call the particular attention of

SHIP-OWNERS, SHIP-BUILDERS, AND COMMANDERS OF STEAM AND SAILING VESSELS,

to the Simple and Efficient Arrangements of their

PATENT PUMPS.



Ships' Pumps

AND

Fire Engines,

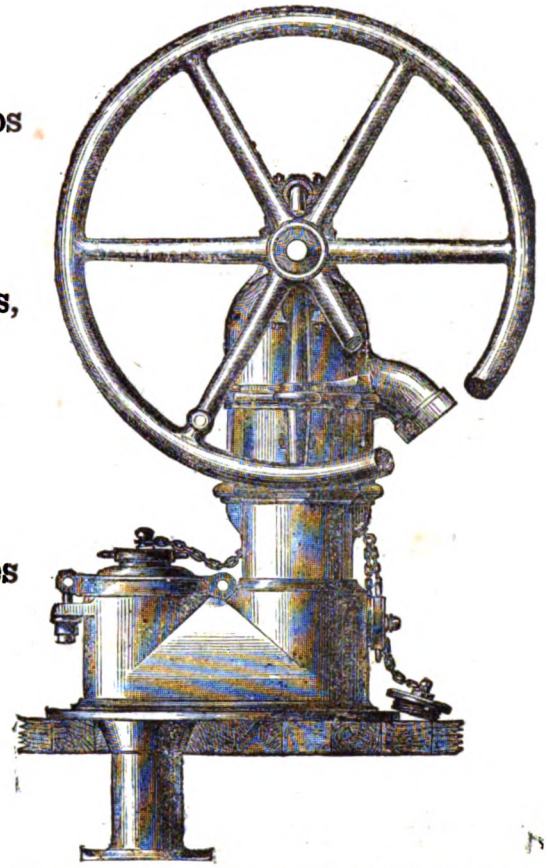
Fixed and Portable.

WITH

Patent Valves

AND OTHER

Improvements.



These Pumps are free from that liability to choke which is common to other Pumps, and their Working Parts are not susceptible of derangement either from wear or from being long out of use. They pass entirely through them, with ease, any substance that may enter the Suction Pipes. The Novelties in these Pumps are their adaptation to the varied duties of Ships' Pumps; the facilities they afford for Cleansing the Suction Pipes, and for Sounding or Examining the Valves; the readiness with which they may be used for Ventilating the Bilge, or for acting as a Syphon either for Watering the Ship, or for extinguishing Accidental Fires on board; the rapidity with which they can be converted into Fire Pumps, or be applied to the Washing of Decks; and their capability of Pumping from Several Compartments.

T. SUFFIELD AND CO.

Also respectfully solicit the attention of STEAM SHIP BUILDERS and OWNERS to their Large and Varied STOCK of

ASSORTED STORES FOR MARINE PURPOSES.

They keep a Large Stock of Goods, of their own Manufacture and from the Best Makers, constantly on view; so that by a visit to their Works or Depôt, much valuable time may be saved by Managers, Engineers, and other Gentlemen who may require such Stores, together with a further saving in the cost of such Articles.

TO ENGINEERS, MILLWRIGHTS, MACHINISTS, &c.

VULCANIZED INDIA-RUBBER

In any of the following forms, of any size, or to Working Drawings for all MECHANICAL *purposes:—*

WASHERS for Steam and Gas Joints.
VALVES for Marine and other Steam Engines.
ENGINE-PACKING (Elastic).
PUMP-BUCKETS ,,
HOSE-PIPES.
GAS-TUBING.
SUCTION HOSE.
FIRE ENGINE AND FACTORY HOSE.
WATERPROOF CART, VAN, AND WAGGON COVERS.
MACHINE AND MILL-BANDS fo Driving all kinds of Machinery.
RAILWAY BUFFER SPRINGS.
BALL VALVES.
PUMP-PACKING (Rings or Rope).
WHEEL-TIRES (Noiseless).

N.B.—A Large Stock of the above always on hand, and any modification made to order.

Please address all communications to the Manufactory,

JAMES LYNE HANCOCK, VULCANIZED INDIA-RUBBER WORKS,
Goswell Road, London, E.C. (85)

RIFLED FIRE-ARMS, CANNON, and PROJECTILES.

Now ready, in 8vo. with Illustrations, price 5s. cloth,

MISCELLANEOUS PAPERS on MECHANICAL SUBJECTS: Including a Treatise on RIFLED FIRE-ARMS, CANNON, and PROJECTILES. By JOSEPH WHITWORTH, F.R.S.
London: LONGMAN, BROWN, & Co., Paternoster Row. (144)

WORKS PUBLISHED BY BLACKIE AND SONS.

RAILWAY LOCOMOTIVES.

THEIR PROGRESS, MECHANICAL CONSTRUCTION, and PERFORMANCE, with the recent Practice in England and America. Illustrated by an extensive Series of Plates, and numerous Engravings on Wood. By DANIEL KINNEAR CLARK, C.E. To be completed in about 22 parts, imperial 4to, 2s. 6d. each.

This work will combine the Locomotive Section of the Author's Treatise on Railway Machinery, with extensive additions illustrating the practice of English Locomotive Engineers of the present day, and presenting the most recent attainments in American practice. It will also include the consideration of a variety of questions bearing upon the improvement and economical working of the Locomotive.

Parts 1 *to* 12 *now ready.*

RAILWAY MACHINERY.

A Treatise on the Mechanical Engineering of Railways; embracing the Principles and Construction of Rolling and Fixed Plant, in all departments. Illustrated by a Series of Plates on a large scale, and by numerous Engravings on Wood. By DANIEL KINNEAR CLARK, C.E. 2 vols., half morocco, £4 15s.

RECENT PRACTICE IN THE LOCOMOTIVE ENGINE.

Being a Supplement to "Railway Machinery." Comprising the most recent Improvements in English Practice, and Illustrations of the Locomotive Practice of the United States of America. By DANIEL KINNEAR CLARK, C.E. To be completed in Eight Parts, imperial 4to, 2s. 6d. each.

This work will consist simply of the new portion of Railway Locomotives announced above. It is published separately for the benefit of those who already possess the Author's Work on Railway Machinery.

Parts 1 *to* 4 *now ready.*

BLACKIE & SON, Warwick-square, City, London; and all Booksellers. (126)

HALKETT'S GUIDEWAY STEAM AGRICULTURE will be Exhibited at Canning-place, Kensington Toll Gate, South of Kensington Gardens, on Wednesdays, the 9th, 16th, and 23rd of February, and to private view upon previous appointment. By this system, every operation of the Farm is performed by Steam Power, the land largely increased in value, and the cost of cultivation greatly reduced. A paper read before the Society of Arts, illustrations, &c., will be forwarded upon application to the Office, 80 Chancery-lane, W.C. (104)

ARTESIAN WELLS, BORING TOOLS, PUMPS, &c. Engineers, Architects, Surveyors, Builders or others requiring a good supply of Water may have any quantity procured by W. SPELLER, 14 York-street, Blackfriars'-road, London, where may be had any quantity of Tools for Sinking or Boring, from 2 to 20 inches diameter, and from 100 to 2,000 feet depth; also Men and Tools to bore for Railroads, Minerals, &c., in any part of the world. Boring Tools and suitable Pipes for exportation, with full instructions for their use.

Builders, Contractors, Brickmakers, Barge and Ship Builders, and others, can be supplied with Wrought or Cast Iron Pumps, Double or Single, for excavation of Deep Wells, from 3 to 14 inches in the bore, and from 6 to 130 feet in length, to work by Hand or Steam Power..

Hot-water Apparatus for Conservatories, &c., on the most economical and improved principles.

Also Manufactory for Captain John Grant's much improved Cooking Apparatus. (44)

New Publications of H. Bailliere.

ENGINEERING PRECEDENTS FOR STEAM MACHINERY; embracing the Performances of Steam Ships, Experiments with Propelling Instruments, Condensers, Boilers, accompanied by Analysis of the same; the whole being Original Matter. By B. F. ISHERWOOD, Chief Engineer of the U. S. Navy. 8vo, Plates, 6s.

MULLER'S PRINCIPLES OF PHYSICS AND METEOROLOGY; with 530 Woodcuts and Two Coloured Engravings. 8vo, 18s.

WEISBACH'S MECHANICS OF MACHINERY AND ENGINEERING. Two Vols., 8vo, with 900 Woodcuts, £1 19s.

KNAPP, RONALDS, AND RICHARDSON'S CHEMICAL TECHNOLOGY; or, Chemistry in its Applications to the Arts and Manufactures.—Fuel and its Applications. Vol. I., in 2 Parts, 8vo, most fully Illustrated with 433 Engravings and 4 Plates. £1 16s.

(This is the Second Edition of Knapp's Technology.)

Vol. II., 8vo, contains: Glass, Alum, Potteries, Cements, Gypsum, &c. With numerous Illustrations, £1 1s.

Vol. III., 8vo., contains: Food Generally, Bread, Cheese, Tea, Coffee, Tobacco, Milk, Sugar. With numerous Illustrations and Coloured Plates, £1 2s.

QUEKETT'S (JOHN) PRACTICAL TREATISE ON THE USE OF THE MICROSCOPE. Third Edition, with 11 Steel and numerous Wood Engravings. 8vo., £1 1s.

GRAHAM'S ELEMENTS of CHEMISTRY, including the Application of the Science in the Arts. Second Edition, with numerous Woodcuts. 2 vols., 8vo., £2.

NICHOL'S ARCHITECTURE OF THE HEAVENS. Ninth Edition, with 23 Steel Plates and many Woodcuts. 8vo., 16s.

H. BAILLIERE having a house in France, America, and Spain, is enabled to supply all Foreign Scientific Publications as soon as published. He also begs to call attention to his Large Stock of Scientific works, of which a Catalogue will be sent on application.

London: H. BAILLIERE, Publisher, 219 Regent-street. (136)

PATENT WEDGE and GROOVED SURFACE FRICTIONAL GEARING.—The PATENT FRICTIONAL GEARING COMPANY, Proprietors of ROBERTSON'S WEDGE SURFACE FRICTIONAL GEARING PATENTS, grant Licences to Users of Machinery, for the unlimited use of the System in their Works, on very moderate terms, enabling them to make or order from any Mechanician the Machinery they require.

The Company possess Five Patents relating to this Frictional System, including (in addition to their Bevel and Mitre Wheels) a System of Disc Clutches and Clutch Movements, Wheel Clutching, Reversing, Differential, Speed Ring, Varying Speed, and Break Movements, and of Shafting, Pillow Blocks, Shafting Hangers, &c.

Frictional Wheels thus formed are applicable to the heaviest as well as the lightest kind of work, and, in addition to their being extensively in use for ordinary gearing purposes, have been in use for a considerable time applied to Mills for Rolling Iron, the Screw-Propeller, Incline-Winding Engines, Saw Mills, Pumping Engines, Flax Scutchers, Fan Blowers, Calico-Printing Machinery, Steam Winches, Cranes, Hoists, &c.

This system gives great facilities for simplifying Machines, and for mechanical combination, and has the advantage of being noiseless and cleanly, there being no oil or grease used on the wheels. Wheel Catalogues and Circulars, giving particulars, sent free by Post; also a list of manufacturing Agents, and information regarding those who, from locality or experience, are best able to execute orders for the description of work required.

Office, 20 Buchanan Street, Glasgow. (146)

TO WIRE ROPE MAKERS.—ARCHIBALD SMITH is now prepared to GRANT LICENCES for the use of his PATENT ROPE MACHINERY, guaranteed to work at six times the speed of any other, and to save upwards of fifty per cent. in the cost of making. It is used by the most eminent makers, and was also in the manufacture of the Atlantic Cable.—Apply to 69 Princes-street, Leicester-square, W. (8)

REMARKS.—Our Markets continue quiet, but very steady. Prices almost without change.

LAWRIE AND HAGGER, Metal Brokers.

33 Lombard-street, E.C.

METAL AND COAL TRADES, &c.

[FROM OUR OWN CORRESPONDENT.]

State of the Iron Trade Generally—The South Staffordshire Trade in Iron and Coal—Mr. Riley's Bankruptcy—Monmouthshire and South Wales Trade—Derbyshire, Lancashire, and Yorkshire Iron and Coal Trades—Liverpool Iron Trade—Glasgow Pig Trade—Birmingham; Wolverhampton, and Sheffield Trades—Prices of Metals—Barnsley Hand Loom Trades—The Centres of the Textile Trades—The Flint Glass Makers' Dispute.

GENERALLY the iron trade continues quiet. Some of the leading houses are well employed, and orders from America continue to arrive to a fair extent, but the general account is that the demand is decidedly less active than was anticipated in the early part of the quarter; the result, as is supposed, of the fears entertained lest peace should be disturbed. There are some good orders for rails in the market for India, and also home consumption.

In South Staffordshire the iron trade still continues quiet, its position being much the same as we last reported it, without any tendency to retrogression. There is a fair amount of work in progress at the various mills and forges of the district, and the producers of the best descriptions of iron are well supplied with orders. Prices continue tolerably firm, viz., bars, £7 10s., hoops, £8 10s., and sheet-iron, from £9 to £9 10s. per ton. The demand from the United States is increasing, and there seems to be no question that as the season advances the advices from that country will be considerably augmented, especially if due regard be paid to the quality of iron manufactured. There is a good demand for first-rate hot blast mine iron, which is realizing £3 15s. per ton, excepting in some instances, where parties are pressing for cash payments. In these particular cases lower rates are accepted. Ironstone, the yield of the district, is in good demand, and is realizing, according to quality, from 15s. to 17s. per ton. In consequence of the mildness of the season, the demand for coal as far as regards domestic consumption has fallen off considerably, but the requirements for the various works is much the same as usual. The colliers still continue to agitate the question of an advance of wages, but there is not at present any prospect of their effort being attended with success.

On Friday Mr. W. T. Riley, ironmaster, late of the Mill-fields, Bilston, underwent another long examination touching his accounts in the Birmingham Bankruptcy Court. Nothing fresh was elicited. The learned commissioner deferred his decision.

In Monmouth and South Wales the demand for both coal and iron continues steady. Orders for railway iron from the continent have been received; the home enquiry for pigs is good.

In Derbyshire, Lancashire, and Yorkshire there is a steady demand for most descriptions of iron, and orders are given out more freely than a short period ago. The facilities offered by the Government for the construction of railways, appear likely to occasion a good demand for railway iron throughout the spring, and in anticipation of this state of things several manufacturers are extending their works, with a view the more readily to meet the increased demand which will be no doubt made upon them. The coal trade is brisk, but the extreme mildness of the weather occasions a slackness in the demand for household purposes. The rates are well maintained.

At Liverpool orders for manufactured iron continue to be given slowly, but makers are fairly occupied, and prices are well maintained. The price of common Welsh bars is £6 15s. to £6 17s. 6d.; Staffordshire, £7 to £7 2s. 6d.; and hoops, £8 5s. to £9 per ton. On Tuesday the following was the quotation of the Liverpool pig-iron market:—Buyers, 52s. 3d. cash; 53s. three months open; sellers, 52s. 9d. cash, and 53s. 6d. three months open.

Respecting the Scotch pig-iron, whilst a good business was done in Glasgow at the close of last week, at a fall of from 1s. to 2s., the price terminating at 51s. 3d. cash, for mixed warrants, on Tuesday business was done at 52s. 6d., one month open, closing very firm, with not much iron offering. Nos. 1 and 3, G. M. B., 53s. 3d.

The staple trades of Birmingham and Wolverhampton are not marked by any perceptible alteration since last week. The factors speak favourably of the country business, and the orders received from travellers since Christmas, if not unusually heavy, are of an average character. The foreign trade is, however, still quiet. Tin-plate, japan, and lock manufacturers are fairly employed, and hollow-ware trade shows faint signs of improvement.

From Sheffield we have the following:—"There are further signs of improvement in the general trade of the town and neighbourhood. Most of the country houses continue moderately busy in steel files, tools, and cutlery; and some of the foreign houses now receive more favourable accounts from their correspondents. We hear of instances in which recent advices from the United States have been more satisfactory than for a very considerable period. This refers chiefly to the heavy branches of the Sheffield trade. There is also, we believe, an increased and increasing demand for Britannia metal goods. For some time there has been a gradual decrease in the list of unemployed poor."

With the exception of a slight decline in spelter, there has been no alteration in the past fortnight in the quotations of metals.

Since Christmas the Barnsley linen trade has been very dull, and little work has been given out to the handloom-weavers. There are 700 or 800 of these looms in the Barnsley district, the machinery of which has cost something like £10 per loom; and most of these looms at present, and for many months past, have had very little work. The manufacturers by power are giving full employment to their weavers, and have been doing so for the last fortnight.

Upon a comparison, however, of all the accounts that we have received from Liverpool, Manchester, Leeds, Halifax, Bradford, Rochdale, Huddersfield, and Nottingham, with last week's accounts, we have no difficulty in stating that as upon the whole the textile trades are not in a worse state, and as some of them are decidedly in a better, the prospects of the iron and metal trades generally have much improved in the six days.

The flint glass trade is gradually going to Germany, owing to the dispute between the men and their employers. The latter met at Crewe on Tuesday, and invited a deputation of the men to meet them, but as they announced that certain concessions by the men would be necessary, the men refused the invitation, and the masters adjourned to the 3rd of May. The lock-out is therefore to continue three months longer.

LIST OF MISCELLANEOUS TENDERS INVITED, AND ENGAGEMENTS OPEN.

The tenders and vacancies which appear in this weekly list are not repeated in succeeding numbers.

RAILS, *East India Railway Company.*—For 15,000 tons of rails, 130 tons of bolts and nuts, and 4,000 tons of chairs (Ransome's patent). Specifications, &c., at company's offices. Tenders by noon 18th March, at East India Railway House, Alderman's Walk, New Broad-street.

RAILWAY WORKS, *London, Brighton, and South Coast.*—For construction of first section of Shoreham, Henfield, and Mid-Sussex, a distance of about ten miles. Specifications, &c., after 21st, supplied on payment of £3. Tenders by 11 a.m., March 10 (attendance).

RAILWAY WORKS, *Guisborough.*—For construction of a portion of the Cleveland Railway (about four miles.) Plans, &c., of J. Hawkshaw, C.E., 33, Great George Street, Westminster, and at office of Messrs. Reed, Stockton-on-Tees, on the 22nd instant. Tenders at Messrs. Reed's office on Monday, 28th instant.

RAILWAY WORKS, *Scotland.*—For extension of branch to Port Carlisle Railway (about half-a-mile.) Assistant engineer will attend at British Hotel, Carlisle, Monday, 21st February, and Tuesday, 22nd, at 10 o'clock, to exhibit plant, &c., which afterwards may be seen at office of Messrs. B. and E. Blyth, 135, George-street, Edinburgh. Tenders to Secretary, Caledonian Railway, 55, Renfield-street, Glasgow, on March 1.

STEEL, *East India Company.*—The East India Company invite tenders for steel. Conditions, &c., at Secretariat office, East India House, to 11 on 22nd inst., when offers must be sent in.

COOKING APPARATUS WANTED, *West Riding Asylum, Wakefield.*—The Visiting Justices invite makers of cooking apparatus to send in plans and estimates. Information on application, by letter, to clerk of works, Asylum, Wakefield.

IRON BUILDING, *Trowbridge.*—For an iron building of three sides and roof complete. Address, Rev. J. H. W., Post-office, Trowbridge, Wilts.

PIERS, *Watchet.*—For construction of piers, &c., to plans, which may be seen at office of Watchet Harbour Commissioners, Watchet, Somerset; or at office of the engineer, J. Abernethy, Esq., 3 Parliament-street, Westminster. Tenders on 5th March, to Mr. C. E. Rowcliffe, clerk to commissioners, Stogumber, Taunton, Somerset.

PIT SINKING, *Whitworth.*—For sinking of two pits at Bishop's Close, Whitworth, for the Weardale Iron Company. Particulars, &c., at Tudhoe Iron Works, Newcastle-upon-Tyne, or of Mr. W. Burrell, Black Prince Colliery, Tow Law. Tenders on the 23rd Feb.

IRON LIGHT-HOUSE, *Scotland.*—For construction of a malleable iron beacon. Plans, &c., by Messrs. Stevenson. Plans at 84, George-street, Edinburgh, from 10 till 3. Tenders to Northern Light-house office, Edinburgh, on 21st instant.

SWORDS AND SCABBARDS, *East India Company.*—Particulars at Secretariat office, and tenders there by 11 a.m., 25th instant.

GAS RETORTS, *Walsall.*—The Walsall Improvement Commissioners want tenders for about thirty best fire-clay retorts, and bricks to fix them. Tenders to the clerk on 25th instant.

BOILER, *Watford.*—For cylindrical or Cornish boiler at Waterworks of Local Board of Health, Watford. Information of Mr. Pilbrow, C.E., Tottenham, engineer to the Board. Tenders to Board by 24th instant.

GASHOLDER TANK, *Rugby.*—For erection at works of the Rugby Gas and Coke Company, of a cast-iron gasholder tank, and for a gasholder with cols, girders, &c., according to the plans, &c., at the office of the company, Rugby. All particulars of Mr. Simpson, Gas Works, Rugby. Tenders to the Secretary on March 5.

IRON WATERING CARTS, *Stratford.*—The trustees of Middlesex and Essex turnpike roads; for repairing and keeping in repair 15 iron watering carts. May be inspected at the wharf of Messrs. Meeson and Co., at Stratford, Essex, near Bow Bridge, adjoining river Lea. Tenders at the office, Bow, Middlesex, on 24th.

MATERIALS FOR CONVICT PRISONS. For supply of timbers, deals, slates, lime, sand, bricks, lead, glass, wrought and cast iron, ironmongery, gas and water pipes, white lead, oils &c., for twelvemonths from 1st of April next to 31st of March, 1860, for Pentonville, Millbank, Brixton, Pottland, Portsmouth, Dartmouth, Chatham, Lewes, and Parkhurst prisons, and Fulham Refuge. Tenders to director of convict prisons, 45 Parliament-street, Westminster, by 6, p.m. March 14. Forms there by 24th inst.

WATERWORKS, *Wallasey.*—For a water tower, for Board of Health for Wallasey, Chester. Drawings, &c., on payment of one guinea, from Local Board, or at the offices of R. Rawlinson, Esq., C.E., 31 Parliament-street, Westminster. Tenders to office of L. B., Church-street, Egremont, Cheshire, on 24th inst.

SEWERS, *St. Martin-in-the-Fields.*—For jobbing and measured works, for sewers and drains in the parish from Lady Day next. Printed forms, &c., of Mr. Burstall, surveyor to the vestry, 15, Castle-street, Long Acre, for 5s. Tenders at the Vestry House before 4 on 3rd of March.

REGIMENTAL SCHOOLS, *Woolwich.*—For additions, &c., to Government Regimental Schools, Green Hill, Woolwich. Specifications, &c., to the 23rd inst., at Royal Engineer's office, Artillery Barracks, Woolwich. Tenders by noon on 28th inst., to Director of Contracts, War Office, Pall-mall. The time for completion extended from three to nine months.

MARKET HOUSE, *Midsomer Norton.*—For erection of a market house at Midsomer Norton. Plans, &c., of Mr. T. H. Smith, Midsomer Norton, and of Messrs. Foster and Wood, architects, Park-street, Bristol. Tenders to Feb. 28.

SCHOOLHOUSE, *Lanark.*—For masons', joiners', slaters', plumbers', and plasterers' work in a new school-house at Lanark. Plans, &c., of Mr. Ponstie, Carstairs Mains; to whom tenders, March 12.

HOUSE, *Gateshead.*—For erection of a large house at Gateshead. Plans, &c., up to the 25th inst., at offices of Mr. M. Thompson, architect, 5 Eldon-square, Newcastle-upon-Tyne.

Chelsea.—Horses, carts, and drivers, for Chelsea, from 25th March next, to 18th March, 1860; forms at office of vestry, Manor House, 111 King's-road; tenders there by 3 o'clock, 22nd inst.

ROAD SUPPLY, *Greenwich.*—For broken Guernsey granite and broken flints; particulars, &c., at turnpike gates, at clerk's, Croom's-hill, Greenwich, or of surveyor, Mr. J. R. Heward, New Cross; tenders to clerk at Green Man Inn, Blackheath, by ten, 26th Feb.

ROADS, *Bury.*—For excavating, sewering, priming, paving, &c., of 1¼ miles of turnpike road, from Strand-lane (Radcliffe) to Whitefield; plans to 22nd inst. at Mr. Slater's, Bury, Lancashire; tenders on the following day to Mr. NORRIS, clerk to board, Bury.

STONE, *Woolwich.*—Separate tenders for 10,000 or 5,000 feet super. of first class York paving. Also 500 feet of Aberdeen, Guernsey, or Devon, Heyter, or Carley hose granite kirb, and for 500 cubic yards of surface picked flints, (broken). Bond required. Particulars of Mr. Barnett, surveyor to Local Board of Health, Woolwich. Tenders at town-hall at 7 p.m., 22nd inst.

GAS ENGINEERS, *London.*—A first class gas engineer wanted by Equitable Gas Light Company. Salary £400 a-year, and residence, free of rent and taxes. Applications to company, 121, John-street, Adelphi, before 22nd instant.

RESIDENT ENGINEER, *Vale of Neath.*—The Vale of Neath Railway Company require a person to undertake the care of about 40 miles of railway. Application by letter to secretary, stated salary required, &c.

FOREMAN ENGINEER, *Dundee.*—Iron engineering establishment a general foreman to superintend the designing and construction of marine and canal engines, &c. Apply to Gourley, Brothers, and Co., Engineers and Iron Shipbuilders, Dundee.

LONDON AGENT WANTED.—To represent a manufacturing establishment, a gentleman well known to railway engineers, managers, and others. A salary and commission allowed. Address M. and Co., *Engineer* Office, 163 Strand.

SURVEYOR OF ROADS, *Newington.*—A surveyor of roads for parish of St. Mary, Newington, Surrey, at £180 per annum. Application to H. and F. Chester, clerks to Vestry, 1 Church-row, Newington-butts, by six, 21st inst.

DESIGNS, *Newcastle-under-Lyne.*—For alteration, &c., of Town-hall. Premium £20. Information with Mr. W. M. Thomas, surveyor, Newcastle. Plans to March 31st.

ROAD SURVEYOR, *Prestwich, Bury and Radcliffe Turnpike Trustees.*—A surveyor, will have entire supervision of roads. Salary £70 per annum. Applications to Mr. Norris, solicitor, Bury, Lancashire, by 2 p.m., 25th inst.

ENGINEERING DRAUGHTSMAN.—W 59, *Manchester Guardian Office.*

FOREMAN OF MECHANICS.—Apply to Wrigley and Son, Bridge Hall Mills, Bury; or at 32, Princess-street, Manchester.

PLANS FOR WORKHOUSE, *Grinstead.*—Plans, &c., for erection of a Central Union Workhouse, near Railway Station at East Grinstead. Plans, &c. forwarded to office of W.A., head clerk to guardians for East Grinstead Union, Grinstead, Essex, 3rd March.

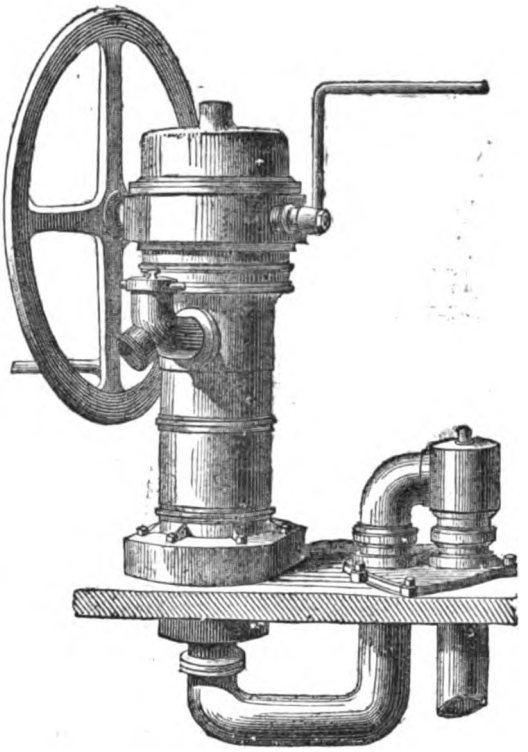
Under the Patronage of the Board of Admiralty.

SHIPS' PUMPS OF HER MAJESTY'S NAVY.

JOSIAH STONE,

Sole Manufacturer of DOWNTON'S well-known and much approved SHIPS' PUMPS, which have been used in preference to all others on board the vessels of Her Majesty's Navy, for upwards of thirty years, and have given the greatest satisfaction, effectually answering all the purposes required of any Ships' Pumps, and capable of throwing most powerful jets of water in case of fire.



These Pumps have also been most extensively used on board merchant vessels, both at home and abroad, and have been supplied to the Royal Navies of France, Prussia, Holland, Russia, Spain, and Turkey. The Pumps are portable, as they may be easily removed from the ship and put to work in a boat alongside in a few minutes. Each pump is fitted with a large foot valve plate (which may be placed in any part of the vessel most convenient), and from which communication is made to any number of distinct compartments in the vessel. In case of any of these pipes fouling, the water, by an almost momentary attachment, may be forced from the Pump downwards, so as to clear all obstructions, preventing any possibility of stoppage. The valves are of the simplest description, and being faced with ordinary leather discs, the latter may be renewed in a few minutes by the most inexperienced hands. By the peculiar construction of these Pumps, a most perfect and uninterrupted flow of water may be maintained; so uniform as to be undistinguishable from that proceeding from a cistern. The Pumps are made of several sizes, those of 7, 9, and 12 inches bore being most generally used. They may, however, be ordered of any dimensions required, and may be fitted either with one or two fly wheels. A standard, &c., is also supplied with these Pumps, to enable them, when necessary, to be used as ordinary hand-lever pumps.

JOSIAH STONE, Engineer, Manufacturer of all descriptions of PUMPS and FIRE ENGINES for Land and Ships' Use; Brass and Iron Founder and Finisher, Nail and Rivet Maker, &c.

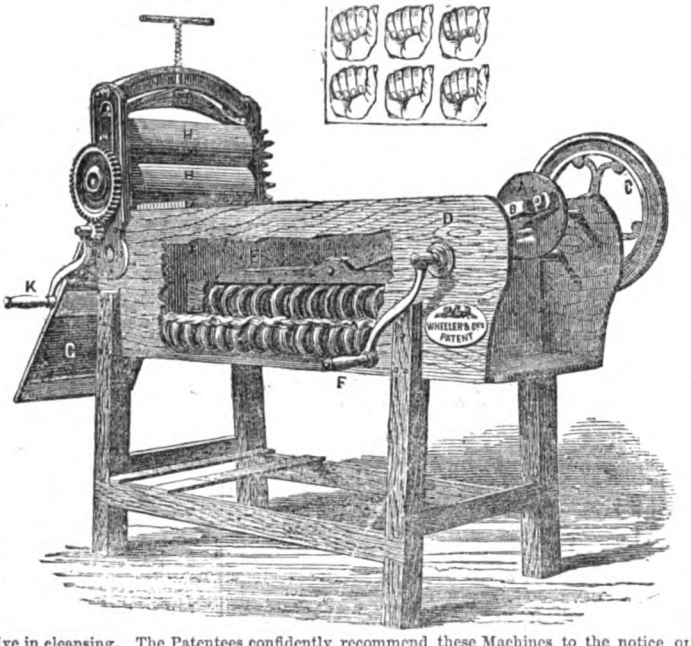
T. WHEELER AND CO.'S
"OXONIAN KNUCKLE WASHING MACHINE."



THE Improvements in these New Inventions are the non-exposure of the user's hands to the dangerous parts of the Machine, and the rapidity with which the work is done. These Machines have neither bands or wheels passing on the outside, wherein lies the liability to accident. The rubbers are the truest representation of the knuckles or hand washing yet brought out; the compensating floating rubbers work at right angles, backward and forward, in the same manner as does the hands. These Machines can be supplied with rubbers that represent a person's hand in the action of rubbing; the knuckles, finger nails, and palm of the hand being truly modelled. They are capable of Washing Clothes of every description whatsoever, the largest bedding to the most delicate piece of muslin can be washed without breaking a single thread; in fact, such is the delicacy of the action of these Machines, that the paper you are now reading can be passed between the rubbers without sustaining any injury, at the same time being thoroughly effective in cleansing. The Patentees confidently recommend these Machines to the notice of Laundresses, Heads of Families, Hotels, Emigrants, &c. So simple is the action of this Machine, that a boy or girl of 10 or 12 years of age can work it; the only skill required is to soak the clothes one hour before placing them in the Machine, placing a portion of the clothes at the handle end of the Machine; laying on the rubbers a part of them; turn the handle, and the clothes will pass through between the rubbers to the opposite end, effecting a saving of at least 50 per cent.

Prices: Washing Machines, £1 6s., £2 6s., £3 6s., £4 10s., £5 15s.; Washing, Wringing, and Mangling, £8 £10 15s., £14 14s.—Full Instructions sent with every Machine. Testimonials or References sent on application.

MANUFACTORY, ALBION WORKS, PARK END STREET, OXFORD (114)

TO BRASS-FOUNDERS, ENGINEERS, &c.

THE PATENT PLUMBAGO CRUCIBLE COMPANY having completed the enlargement of their premises, beg to call the attention of all users and shippers of Melting Pots to the great superiority of the PATENT CRUCIBLES, which have been used during the last three years by some of the largest melters in England and abroad. In addition to their capabilities of melting an average of from thirty-five to forty pourings; they are unaffected by change of temperature, never crack, but can be used till worn out, requiring only one annealing for several days' work, and become heated much more rapidly than ordinary pots, effecting thereby a saving of more than fifty per cent. in time, labour, fuel, and waste. The Patent Plumbago Crucible Company also manufacture and import clay crucibles, muffles, portable furnaces, sublimate pans and covers, glass-pots, all descriptions of fire-standing goods, and every requisite for the assayer and dentists. For Lists, Testimonials, &c., apply to Battersea Works, London, &c. (43

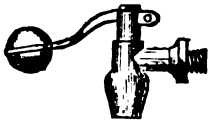
(108)

HIGH-PRESSURE VALVE-COCKS,
LAMBERT'S PATENT.

Equilibrium Ball Valve. Cottage Closet Valve.



The Equilibrium Ball-Valve is simple and certain in its action, and is cheaper than the common cocks now in use.

The Cottage Valves are suitable for application to any kind of basin; and, as they shut against the pressure, no concussion in the pipes can possibly occur.

These cocks have been extensively and most successfully used in many towns, under continuous high pressure, varying from 100 to 350 feet; their efficiency and durability is, by experience, established.

THOMAS LAMBERT and SON,

Brass Founders, Short-street, New-cut, Lambeth.

(86)

PUMPING MACHINERY.

GWYNNE AND Co., Engineers, London, manufacture and supply the following Machinery, of the most approved construction and with all the latest improvements:—Portable and Fixed Steam-Engines and Boilers of every description; Waterwheels, Windmills, Horse and Hand-power Machines; Pumping Machinery for the Supply of Towns, Cities, and Districts, and for the Irrigation of Coffee, Cotton, Indigo, Sugar-cane, and Rice Estates, for pumping out Coffer-dams, Canals, Dry Docks, Reservoirs, &c. They also manufacture and supply the Pumping and other Machinery for Paper, Pulp, and Fulling Mills, Breweries, Distilleries, Tanneries, Starch Works, Bleaching, Dyeing, and Calico Printing Works, Chemical Works, Silk, Cotton, and Flax Mills, and Manufactories in general. All Letters not paid will be refused. Illustrated Price Lists forwarded on receipt of Six Postage Stamps.—GWYNNE AND Co., Hydraulic and Mechanical Engineers, Essex-wharf, Strand, London.

For Exportation—The above can be obtained through British Merchants, Shippers, and Colonial Agents. (24)

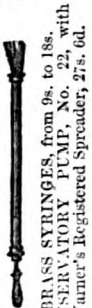
A lighter Pump of 3 inches diameter, can be supplied if required 5 15

IMPROVED LIQUID MANURE OR GENERAL PORTABLE PUMP.

These Pumps are fitted with J. Warner and Son's Patent Bucket and Sucker, and cannot clog in action. The Barrel is of Galvanized Iron, not likely to corrode, and can be raised or lowered at pleasure. The legs will fold together, and the whole may be carried on shoulder to any pond or tank required.

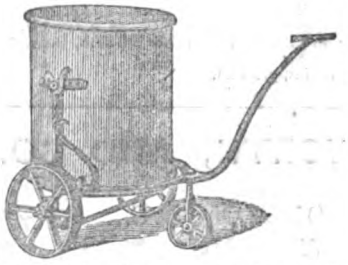
4½ in. Liquid Manure Pumps, with legs, £3 3s.; 1¼ in. Gutta Percha Suction Pipe, 1s. 11d. per foot; 2 in. Flexible Rubber and Canvass Suction Pipe, on Wires, 3s. 3d. per foot. The Barrel is 27½ inches long, and the legs are 5 feet high. Larger sizes of the above if required.



BRASS SYRINGES, from 9s. to 18s.
CONSERVATORY PUMP, No. 22, with Warner's Registered Spreader, 27s. 6d.

Galvanized Iron Tub GARDEN ENGINE, with Warner's Registered Spreader, is strongly recommended for durability and low price, viz., £2 19s., to hold Ten Gallons. Larger sizes, in either wood or iron.

WARNER'S SWING WATER-BARROW.
(To hold Thirty Gallons), £3 3s.,



is intended for all large Establishments where much watering is done by the watering-pot. By its use much time and labour of the Gardener are saved, particularly where the Tank, Pond, or Pump is at a distance from the garden.

MUSICAL SHEEP BELLS, with Straps, in sets of 6, 19s.; ditto, in sets of 8, 25s.; ditto, in sets of 12, 38s.

WARNER'S CATTLE AND SHEEP BELLS, in sets of 6, with Straps, 13s. per set.

Bells for Churches, Chapels, Colleges, Schools, Turret Clocks, &c., cast for any size, note, or weight, singly or in peals. Tuned by machinery. Stocked and wheeled ready for fixing. Old Bells re-cast or taken in exchange.

The great 16-ton Bell, for the Houses of Parliament, was made by JOHN WARNER and SONS, 1856, under their Patent.

May be obtained of any Ironmonger or Plumber, in town and Country; or of the Patentees and Manufacturers, as above. (30)

THE LONDON

WARMING AND VENTILATING COMPANY,

(LIMITED,)

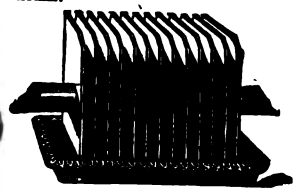
36 GREAT GEORGE STREET, Westminster, S.W.

(MANAGER—Mr. WOODCOCK.)

Churches, Greenhouses, Offices, and Buildings of every description warmed by means of a modification of the plan successfully used during the last five years by Mr. Goldsworthy Gurney in both Houses of Parliament.

Steam, Hot-water, Gas, and in open or enclosed fireplaces, Coal and Coke are equally available for the process.

The cost is less and the effect greater than that of any other known means.



The Horticulturist will find herein an instrument of new and important powers.

The apparatus may be seen in ST. PAUL'S CATHEDRAL, the various offices of the "Department of Science and Art," and in many churches and other buildings.

Particulars and Testimonials forwarded on application.

VENTILATION WITHOUT FLUES.

KUKLA'S PATENT STOVES,

At 18s., 25s., and 50s.

KUKLA'S newly-invented Deflagrator—the first and only perfect GAS STOVE. Guaranteed to burn without flue—without dust, smell, or smoke, producing a great and pure heat with the least expenditure of Gas.—*Vide Society of Arts' Journal.*

Patronised by the English and French Government.

Scientific in Principle,
Simple in Construction,
Healthy and efficient in use.

The Deflagrator Stove is cheap, portable, and suited for every situation; and from the principle on which it is constructed (viz., expanding to a sixfold volume the gas used) is capable of warming any given space more quickly and more thoroughly than any other means: while its addition forms a sure remedy for any ill-warmed or ill-ventilated apartments.

The 25s. Deflagrator warms a room of 2,000 cubic feet at a cost of 3d. per day.

The 50s. Deflagrator warms 5 to 6,000 cubic feet at a cost of 6d. per day (twelve hours).

Also, the Greenhouse Stove at 18s.

Patentee and sole Manufacturer, F. X. KUKLA, 194 Pentonville-road, London.

Country orders promptly attended to. Carriage free to any Railway in London.

Post-office Orders should be made payable to FRANCIS XAVIER KUKLA, General Office.

N.B.—Every Stove separately tested before sent out.

The New Gas Cooking Stove for 10 persons, price £3.

(103)

CLAYTON, SHUTTLEWORTH, AND CO.,

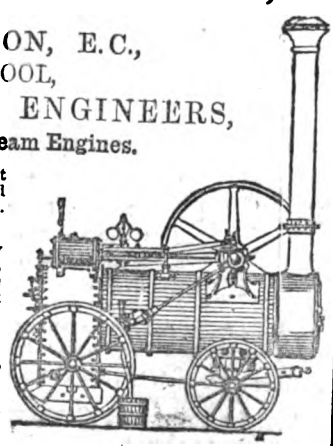
OF LINCOLN,

78 LOMBARD STREET, LONDON, E.C.,

AND 36 DALE STREET, LIVERPOOL,

AGRICULTURAL AND GENERAL ENGINEERS,

And Manufacturers of Portable and Fixed Steam Engines.



Combined Threshing Machines, which dress the corn ready for market at one operation. Grinding Mills, Saw Benches, Pumps for Irrigation and Mining purposes, with all necessary gearing for being driven by steam power. Full particulars and estimates given on application to the above address.

C. S. and Co.'s PORTABLE STEAM ENGINES are adapted for every purpose to which steam-power can be applied. When intended for winding, they are fitted with reversible link motion and winding gear. They are easy of removal, as may be seen by the engraving, and can be set to work immediately on arrival.

C. S. and Co. are now doing an extensive foreign and colonial business, and are prepared to send off engines and machinery of the before-mentioned kinds in a few days from the date of order. They would also call attention to the important *reduction in prices* made for the new year.

For Exportation.—The above can be obtained through British Merchants, Shippers, and Colonial Agents.

(23)

WATER POISONED BY LEADEN PIPES.

"The above engraving represents accurately a section of a leaden pipe, which was employed for a short time in conveying water from a well on the grounds of Mr. Dick, of Bonchurch, Isle of Wight. The water has cut these deep pits almost through the pipe, and not only upon the portion which we have illustrated, but has formed similar chasms throughout the entire length."—*Expositor.*

Poisoned Water Preventable.

BY THE USE OF GUTTA PERCHA TUBING.

The Gutta Percha Company have been favoured with the following letter,

From Dr. MURRAY, Hull.

"It is impossible to conceive of anything more injurious, or destructive to the health of the community than the use of *leaden pipes* for the conveyance of water. The poisonous salts of lead thereby communicated are most insidious and subtle. I hail with gratitude the substitution of Gutta Percha Tubing. I have had the leaden pipe of my own house removed, and its place supplied with one of Gutta Percha. Nothing can be better. I have also recommended it to others, who have adopted the expedient.

Resistance for Frost.

The Gutta Percha Company have been favoured with the following Letters in reference to the non-conducting properties of Gutta Percha Tubing, in the resistance of Frost.

From J. ARMSTRONG, Esq., M.D., Gravesend.

"My private house, which was supplied with your Gutta Percha Tubing some five or six years ago, has never required the slightest attention; and previously, there was no winter passed that we were not deluged in consequence of the bursting of the leaden pipes."

From HENRY BROWN and SONS, Western Works, 108 Rockingham-street, Sheffield.

"We have now a positive proof of the frost-resisting properties of the Gutta Percha Piping. On our premises we have a leaden Pipe and a Gutta Percha one lying side by side. The leaden one has been completely frozen up at least ten days, and the Gutta Percha one is still unaffected.

PUBLIC EXAMINATIONS in ELEMENTARY DRAWING.—PUBLIC EXAMINATIONS in DRAWING, conducted by the SCIENCE and ART DEPARTMENT, will be held in the month of March next, at the District Schools of Art, at

Finsbury—William-st., Wilmington-square	St. Thomas, Chaterhouse, Goswell-street
Lambeth—Prince's-road	Rotherhithe—Deptford-road
Hampstead — Dispensary-building, New-end	South Kensington, Cromwell road
St. Martin's, Castle-street, Long-acre	Spitalfields—Crispin-street
	St. George's-in-the-East

The examination will be of two grades of proficiency, and are open to all persons, without distinction (males and females), and whether taught in a School of Art or not, provided they have not been examined within the last twelve months.

Persons who wish to be examined must send to the Secretary of the Science and Art Department, South Kensington, on or before the 3rd of March, their names and addresses, and the name of the district school to which they desire to come up for examination; and state the subjects in which they are prepared to be examined. Due notice will then be given them of the precise time of examination. Schoolmasters wishing to have several of their scholars examined are only required to furnish the number who will attend for any of the above subjects.

Further information may be obtained of the Secretary of the Science and Art Department, South Kensington, W.

By order of the Committee of Council on Education,

HENRY COLE, Sec. (155)

GLADSTONE & Co., CONTRACTORS and ENGINEERS.
2 John-Street, Minories, London, E.C.,
Are prepared to ESTIMATE FOR and CONSTRUCT BRIDGES, PIERS, JETTIES, &c., in Iron, Wood, or Stone. Also to supply Cranes, Girders, Turntables, and Railway Work and Plant generally. (56)

ENGINEERING AND MECHANICAL DRAWING CLASSES.—Instruction given in Engineering and Mechanical Drawing, comprising the preparation of plans, elevations, and sections of marine and locomotive engines, with the detail and working drawings; also the method of delineating screws, bevel wheels, &c.; orthographical projection, and tinting, shading, and colouring taught.—For prospectuses of the Day and Evening Classes apply to Mr. T. J. HILL, at the offices, 15, Old-street, City-road. (73)

TO MARINE ENGINEERS, OR SHIP-BUILDERS.

THE PROPRIETOR of a VALUABLE PATENT for Double-expansive Marine Engines (by which great economy of space and fuel is obtained) is desirous of entering into arrangements with a respectable firm for the construction of the same. An adequate portion of the patent-right would be assigned by the advertiser to any firm taking the matter up; and he would render all assistance in his power, either in London or elsewhere, amongst ship-owners (to many of whom he is well known), in obtaining contracts, &c. Unexceptionable references given. Address C. E., MECHANICS' MAGAZINE Office, 166, Fleet-street. (76

HART & SON, MALLEABLE IRON-FOUNDERS, 4 Vine-street, York-road, Lambeth. Orders for Malleable Iron Castings executed within a week. (77)

STEAM ENGINES FOR SALE.

PORTABLE STEAM ENGINES, from 6 to 12 horse power,
STATIONARY STEAM ENGINES, from 4 to 50 horse power,
TUBULAR BOILERS, from 4 to 50 horse power,
CORNISH BOILERS, from 4 to 50 horse power,
Are in hand, and can be despatched on eight days' notice. Prices moderate. Workmanship and Material of the best description.
Apply to R. THORNTON & Co., St. Leonard's Iron Works, Edinburgh. (60)

TO BRASS FOUNDERS.

TO BE SOLD, the Patent-right of a New and Highly-approved EQUILIBRIUM WATER COCK or VALVE, suitable for Steam Boiler Feed Pipes, or any cases where the valve is required to be opened against pressure.
Address H., MECHANICS' MAGAZINE Office, 166 Fleet-st., where a Drawing may be seen. (151)

CHUBB'S LOCKS, FIREPROOF SAFES, CASH AND DEED BOXES.
Complete lists of sizes and prices may be had on application.
CHUBB AND SON,
57 ST. PAUL'S CHURCHYARD, LONDON;
28 Lord-street, Liverpool; 16 Market-place, Manchester, and Wolverhampton. (4)

BRICKS.

TO BE LET, with immediate possession, in consequence of the death of the proprietor, J. M. Paine, the DIPPENHALL SILICA FACTORY, erected for the purpose of making improved Fire Bricks, Building Bricks, Paving Tiles, &c., &c., from the Soluble Silica Rock.
Apply to view the Buildings and Bricks to G. H. Ogston, Esq., Resident Manager, Dippenhall, Farnham, Surrey; and for terms, to Messrs. Nicholls and Potter, Solicitors, Farnham. (125)

TO ENGINEERS, ARCHITECTS, PATENT AGENTS, &c.

PHOTOGRAPHS OF THE HIGHEST CLASS and of any size, taken and reproduced at a most moderate rate of charge. Reproductions of faultless accuracy, of Machinery, Models, Drawings, &c. Orders attended to in town and country. Estimates forwarded.
SPENCER, READ, & Co., 4 Agar-street, Strand, W.C. (90)

TO ENGINEERS, INVENTORS, AND OTHERS.

A PRACTICAL ENGINEER of long standing prepares Original Drawings, Copies, and Tracings. Advice and Assistance given to Inventors in working out their Plans. Pupils taught privately. Terms moderate.
Apply to J. J., 171 Strand. (138)

STEAM ENGINES.

FOR SALE, a superior HIGH PRESSURE HORIZONTAL STEAM ENGINE of 6-horse power, 8-inch cylinder, and 1-foot 6-inch stroke. One of 8-horse power, 10-inch cylinder, and 1-foot 6-inch stroke. One of 10-horse power, 12-inch cylinder, and 2-feet stroke. Two of 14-horse power, 14-inch cylinders, and 2-feet stroke; and one of 30-horse power, 20-inch cylinder, and 3-feet stroke.
Apply to Messrs. PAGE and CAMERON, 64 Old Broad Street, E. C., London. (124)

ENGINEERING BUSINESS FOR SALE.

OWING to the continued ill health of the Proprietor, the first-class business of an Engineer and Crane and Block Maker is offered for sale. It has been established in the Metropolis for nearly 30 years, and has enjoyed extensive patronage amongst Brewers, Manufacturers, Warehousemen, and others, in and about London; the business done amounting to nearly £8,000 per annum. About £3,200 would be required, (part of which, however, may remain for any reasonable time on good security,) which is the bare value of the tools, patterns, and stock in trade. The premises, including good dwelling-house, very conveniently situated, and capable of accommodating from 60 to 70 hands, are held upon a long lease, at an extraordinary low rental, not exceeding £100 per annum, taxes included. Many of the tools are nearly new, and of the best construction. The present proprietor, who relinquishes the business solely on account of ill health, would give every assistance in his power to those succeeding him; and as his foreman, who has been with him for nearly ten years, is thoroughly acquainted with the practical parts of the business, any gentleman desirous of commencing as a manufacturing engineer would find the present a very favourable opportunity. As all accounts have been, for many years past, collected quarterly, a very small amount, say £800, would suffice as working capital. Full particulars may be obtained by application to E. E. ALLEN, Esq., MECHANICS' MAGAZINE Office, 166 Fleet Street, E.C. (130)

CAUTION.

TO ARCHITECTS AND BUILDERS.—In consequence of numerous complaints, the Patentee begs to inform the above, that all genuine SMITH'S PATENT DOOR SPRINGS, for Swing Doors, are stamped with Name and Address, thus—SMITH, Patentee, 69 Princes Street, Leicester Square, London; and that Springs thus marked are warranted. SMITH'S PATENT WEATHER-TIGHT CASEMENT FASTENING AND SILL-BARS are admitted by all to be the most perfect invention for the purpose. Diagrams and List of Prices on application. (143)

TO INVENTORS AND OTHERS.—A FIRM of long standing and known respectability, having spare room, steam power, and capital, is desirous of carrying out an Invention (patented or otherwise) of recognised commercial value.
Particulars, by letter *only*, addressed to Messrs. C. and B., 66 Watling-street, E.C. (157)

THORLEY'S FOOD FOR CATTLE.—Every person having an interest in domestic or farm animals should obtain a supply of this celebrated and economical food, which will prove invaluable during the approaching season. For keeping horses in good condition, it is unequalled. Pigs fatten with surprising rapidity upon it, and their flesh increases in flavour and value. Cowkeepers will find great advantage in the increased quantity and improved quality of the milk during its use. All animals are benefited by it. A pamphlet on this interesting subject, accompanied by Testimonials from the principal Nobility, Gentry, and Agriculturists, forwarded on application. In Casks containing 448 Feeds (Measures enclosed), Price 50s., carriage paid to any Railway Station in the United Kingdom. Post Office Orders payable to JOSEPH THORLEY, 77 Newgate Street, London.

N.B.—The public are cautioned against being imposed upon by worthless imitations. (152)

TO STEAM SHIP OWNERS, ENGINEERS, AND OTHERS.

How's Patent Steam Engine Counters, can be read at sight.

These Counters register the number of revolutions made by an engine or other mechanism. They may be used for ascertaining the duty of Pumping Engines and Water-wheels; the revolutions on board a steam-vessel; to calculate the slip of the propeller; and in a locomotive to test the slip of the wheels.

How's Patent Salinometer, for Steam Boilers using Salt Water.

By these, the density of the water in the Boiler is at all times accurately shown, and a saving of boiler and fuel is effected. They are adopted by the Admiralty, the Honorable Trinity Corporation, and others. Copies of Testimonials from Messrs. Penn, Messrs. Maudslay, and others, will be forwarded on application.

How's Engine-Room Telegraph, for communicating between Captain and Engineer. Society of Arts Prize Medal, 1855.

sis a Mechanical Telegraph, and by its peculiar construction, error or misunderstanding is rendered impossible. It s now extensively adopted, and gives great satisfaction.

How's Patent Fresh Water Apparatus for Ships' Use.

This apparatus is designed for the distillation of Fresh from Salt Water; and on long voyages, and where the supply of water is scanty, it will be found invaluable. Testimonials may be seen.

Patent Steam Pump and Fire-Engine for Ships' Use.

This Steam-pump occupies but a small space; works perfectly noiselessly, and throws an immense volume of water. An Illustrated Circular of Fresh Water Apparatus and Steam-pump combined, free on application.

How's Patent Machine for Cutting Bolts, Rods, Spindles, Wire, &c.

Simple in construction, inexpensive, occupies but little space, and will not easily get out of order.

A Pamphlet Illustrative of the above, sent free by post, on application to

A. P. HOW, ENGINEER,

81 MARK LANE, LONDON.

EVERY DESCRIPTION OF ENGINEERS' TOOLS, ENGINE ROOM STORES, &c., &c., SUPPLIED. (89)

SCOTT'S

PATENT GRASS SEED SEPARATOR,

which entirely extracts the Seeds of "COUCH," "TWITCH," "SPEAR," or "HAIR" GRASS, and other impurities from

PERENNIAL AND ITALIAN RYE-GRASS, &c.,

AND

SCOTT'S PATENT CARROT SEED BEARDING

AND

CLOVER AND TREFOIL MILLING OR DRAWING MACHINE,

which effectually removes the beard from Carrot Seed, rendering it fit for sowing with facility by drill or otherwise, and by the separation of abortive or diseased grains vastly increases its vegetative per centage. By a slight modification it is applicable to the other purposes before mentioned.

These Machines were admittedly the most novel, and, at the same time, the most useful and important to the Farmer of any exhibited at the late SMITHFIELD CLUB SHOW.

They may be seen at work at the Establishment of the Manufacturer,

Mr. T. MIDDLETON, Engineer, Southwark.

Communications to be sent to the Patentee, J. SCOTT, 111 Drummond Street, Euston Square, London, N.W. (48.)

HOBBS'S LOCKS.

The attention of Architects and Builders is respectfully invited to

HOBBS'S NEW MORTISE LOCKS,

Which are now manufactured by PATENT STEAM MACHINERY, and, while superior to any other locks in the market, are sold at a price which defies competition. The Plates are made of number "Twelve Gauge" Iron, and being so thick, the pins cannot be loosened by the constant jarring of the door. The security consists in four double-acting levers, while, to secure unusual freedom of motion and prevent the wear of the parts,

HOBBS'S PATENT FRICTIONLESS FOLLOWER

Is also applied. The retail price of these Locks is 10s., from which a liberal discount is allowed to the trade

HOBBS'S NEW MORTISE LOCKING LATCHES FOR STREET DOORS,

Price 18s. And

HOBBS'S NIGHT LATCHES, RIM OR FLUSH, PRICE 10s.,

Are also recommended, together with every description of Lock required for house and cabinet work. Lists of Prices will be forwarded on application, post free.

N.B.—A complete Assortment of FIRE and BURGLAR-PROOF SAFES (Milner's Patent), fitted with HOBBS'S PATENT PROTECTOR LOCK, POWDER-PROOF.

ALSO, STRONG-ROOM DOORS, CASH AND DEED BOXES, ETC.

Address—Hobbs, Ashley, and Co., 76 Cheapside, E.C.

MANUFACTORY, ARLINGTON STREET, NEW NORTH ROAD. (86)

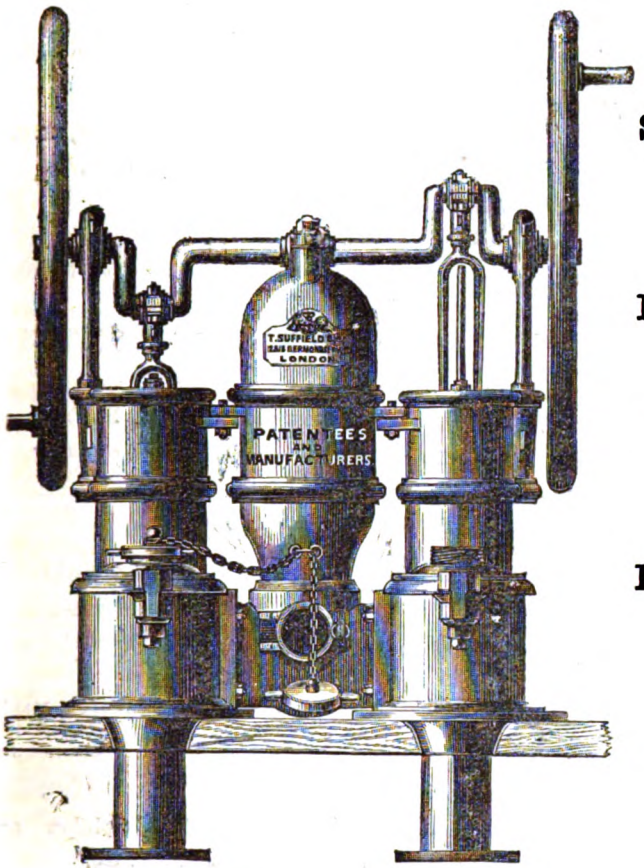
T. SUFFIELD AND CO.

Call the particular attention of

SHIP-OWNERS, SHIP-BUILDERS, AND COMMANDERS OF STEAM AND SAILING VESSELS,

to the Simple and Efficient Arrangements of their

PATENT PUMPS.



Ships' Pumps

AND

Fire Engines,

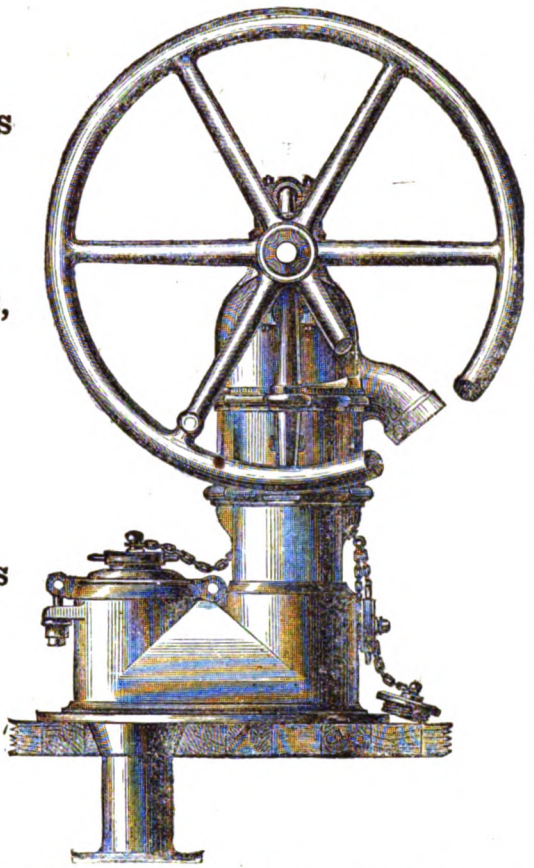
Fixed and Portable,

WITH

Patent Valves

AND OTHER

Improvements.



These Pumps are free from that liability to choke which is common to other Pumps, and their Working Parts are not susceptible of derangement either from wear or from being long out of use. They pass entirely through them, with ease, any substance that may enter the Suction Pipes. The Novelties in these Pumps are their adaptation to the varied duties of Ships' Pumps; the facilities they afford for Cleansing the Suction Pipes, and for Sounding or Examining the Valves; the readiness with which they may be used for Ventilating the Bilge, or for acting as a Syphon either for Watering the Ship, or for extinguishing Accidental Fires on board; the rapidity with which they can be converted into Fire Pumps, or be applied to th Washing of Decks; and their capability of Pumping from Several Compartments.

T. SUFFIELD AND CO.

Also respectfully solicit the attention of STEAM SHIP BUILDERS and OWNERS to their Large and Varied STOCK of

ASSORTED STORES FOR MARINE PURPOSES.

They keep a Large Stock of Goods, of their own Manufacture and from the Best Makers, constantly on view; so that by a visit to their Works or Depôt, much valuable time may be saved by Managers, Engineers, and other Gentlemen who may require such Stores, together with a further saving in the cost of such Articles.

METAL AND COAL TRADES, &c.

[FROM OUR OWN CORRESPONDENT.]

Board of Trade Returns: Export of Metals and Machinery—The Iron Trade in the Past Week in South Staffordshire and other Districts—Coal and the Colliers of South Staffordshire, Wales, and the North—Scotch Iron Trade—Attempt to Resuscitate the Whitby Iron Company—The General Hardware Districts and their Trade.

THE Board of Trade Returns for December, which have been issued only since our last, show that India took the largest amount of British manufactures during the year 1858, the United States ranking second in this respect, and the Australian colonies third. Among the articles which show an increase in the year's exports, as compared with 1857, are machinery, cast iron, and brass manufactures. Annexed is the declared value of the prominent metalliferous products of Great Britain, with coal and culm exported in 1858, compared with the quantity exported in the two preceding years:—

	1856.	1857.	1858.
Coals and Culm	2,826,582	3,210,661	3,052,753
Hardwares and cutlery	3,767,598	4,016,230	3,280,466
Machinery: steam engines	819,067	1,069,269	1,096,288
,, other sorts	1,897,386	2,814,420	2,507,701
Metals: pig iron	1,385,118	1,609,115	1,101,118
,, bar & rod iron	6,217,524	6,262,605	5,223,840
,, iron wire	195,034	242,087	208,444
,, cast iron	712,177	753,334	820,924
,, wrought-iron	3,720,433	3,790,356	3,291,938
,, steel	735,823	748,579	589,781
,, copper, unwrought	673,224	852,055	696,523
,, copper: sheets and nails, including yellow metal	1,664,648	1,673,186	1,620,447
,, other wrought copper	189,181	454,855	381,866
,, brass	121,206	143,953	155,293
,, lead	582,269	549,523	459,656
,, tin plates	1,407,906	1,500,116	1,351,193

The increased exportation of steam engines was chiefly to Russia and Spain, but extended also to India and Australia; while the shipments of other descriptions of machinery diminished in respect of Spain, Holland, and India. The falling off in pig-iron was general, and amounted in the case of Russia to more than one-half. The iron trade of the year may be thus summarised:—

	Pig Iron.	*Bar and Rod Iron.*	*Wrought Iron.*
Prussia	£107,653	—	—
Holland	302,683	£171,624	£158,391
France	194,383	171,753	—
Hanse Towns	—	81,672	—
Sardinia	—	99,082	—
India	—	1,141,420	576,443
Australia	—	149,107	349,599
United States	149,077	663,753	297,975
British North America	28,327	375,303	220,395
Other countries	318,995	2,364,126	1,689,135

The increased exportation of cast-iron is referrable to the demand from Egypt, the United States, and India. Copper and yellow metal sheathing declined, but there was a very large increase in the orders executed for India. The decline in the tin-plate trade was general.

Respecting the iron trade of the country generally it may be stated that fewer orders have come to hand this week than last. The Welsh and North of England firms who have laid themselves out for the rail trade, are more active than the districts dependent upon the general commercial demand. The orders from the States, however, received since our last, have been of as great value as was expected, and the advices thence continue favourable. The existing tariff, it is confidently asserted, will remain unaltered this year. Home orders very sluggish; for the Continent scarcely anything doing. On account principally of the United States demand, the steel houses are in tolerably full operation. Prices of first-class iron remain firm. Makers of less repute are not indisposed to give way a little. The real value of good hot blast pigs cannot be said to be more than £3 10s. At this rate they may be bought for present necessities.

South Staffordshire coal of domestic samples is less active; for manufacturing uses, however, there continues tolerable activity. Stocks are closely worked up. Some of the colliers in that district have struck for an advance of 6d. per day. They are almost confined to Wednesbury and Darlaston, where about 1,000 colliers and stone cutters are "out;" their prospects of obtaining the advance are very slender.

On Saturday about 30 colliers at the mine of Messrs. Stott, Dearden, and Co., Smallbridge, Rochdale, turned out for an advance of 1s. per score tubs. There are now five colliery turn-outs in that locality.

There is an active shipment of rails and coal going forward from Cardiff, the coal and ironmasters of which locality are experiencing an advantage over their brethren at Newport, in consequence of the somewhat restrictive port dues of the latter town. They are such as to induce one of the iron and coal masters of Newport to prepare, it is reported, to transmit to Liverpool by rail instead of by water.

The past week's shipments from Glasgow have been a falling off as compared with the corresponding week last year, of 3,174 tons, the figures being 7,226 tons this year against 10,400 last year. In Glasgow, on Tuesday, No. 1 was quoted at from 50s. 6d. to 50s. 9d.; Mixed Nos., warrants, 51s. 6d. to 51s. 7½d.; Mixed Nos., maker's iron, 50s. 6d. to 50s. 9d.; No. 3, 50s. 6d. to 50s. 9d. Market quiet and steady.

An attempt is being made to resuscitate the Whitby Iron Company, which was destroyed by a landslip. The proposal is to issue preference shares, which are expected to be taken readily by the old shareholders.

In the hardware trades of Birmingham, Sheffield, Wolverhampton, and other towns, there is a feeling on most hands of disappointment at the state of the trade, which is by no means what, at the beginning of the year, it was confidently expected it would be. Travellers report a desire to purchase as existing amongst the country shopkeepers, with, however, an indecision which prevents them from doing so, owing to the fear that England will, before long, be embroiled in a continental war, with a consequent suspension of trade.

LIST OF MISCELLANEOUS TENDERS INVITED, AND ENGAGEMENTS OPEN.

The tenders and vacancies which appear in this weekly list are not repeated in succeeding numbers

CAST-IRON GIRDER BRIDGE.—Over river Weaver, Nantwich. Plans, &c., of T. Bower, jun., architect, Town Hall, Nantwich. Tenders March 2.

GAS WORKS.—Separate tenders for buildings and iron plant for new works for Eltham Gas Light and Coke Co., on Eltham Green, Kent. Plans, &c., Mr. Haworth, surveyor, Eltham. Tenders March 9.

CAST-IRON WATER WHEEL, *Thornton, near Pickering, Yorkshire.*—Construction and erection of, with shafting, &c., at Thornton Paper Mills. Plans, &c., Mr Marsden's warehouse, 53 Orchard-street, Sheffield, until March 1. Tenders March 10.

GAS, *Tutbury.*—Town lighting district. Tenders for supply for one year, to be sent to the Church Sunday School-room, Monday, 7th March. Particulars of Mr. Barber, secretary.

WIDENING MILL BRIDGE, *Acton Trussel, Stafford.*—Plans, &c., County Surveyor, "The Hollies," Stafford, to March 3. Tenders March 7.

CONSTRUCTION OF A MAIN SEWER, *Warrington.*—Drawings and specifications from Mr. B. Payne Coxon, Borough engineer, on and after 23rd inst. Tenders to chairman of Paving Committee, at Town Hall, by 7th March.

RAILWAY, *North British.*—Station-house and office at Leith. Plans, &c., Mr. J. Jopp, C.E., 118 George-street, by 1st of March. Tenders, March 7.

Richman, surveyor, 43 Lower Belgrave-place, between nine and eleven in the morning. Tenders there or at Board Room, Mount-street, Grosvenor-square, 5th March.

ALTERATIONS, *Clay Hill, Bushey, Herts.*—To a house and premises. Plans, &c., of Thomas Lavender, architect and surveyor, Watford, Herts. Tenders there by noon 28th inst.

CHURCH, *Welburn, near Castle Howard, Yorkshire.*—Plans at the Boys' School there. Tenders to Feb. 28.

CEMETERY CHAPEL, *Tong.*—Cemetery chapel and entrance lodge, township of Tong. Plans, &c., of Messrs. Mallinson and Healey, architects, Tyrrel-street, Bradford. Tenders to March 3.

LOCK-UP AND COURT ROOM, *Ingleton.*—Plans with the Superintendent of Police there. Tenders to March 3.

WORKHOUSE, *Leeds.*—Slaters', plumbers', glaziers', painters' work. Drawings, &c., of Messrs. Perkin and Backhouse, architects, Exchange-buildings, Leeds, to March 1. Tenders, March 2.

WAREHOUSE AND DRYING SHED, *Warrington.*—Drawings and all particulars after 24th, at the office of Mr. J. Woolstencroft, architect, 23 Pall-mall, Manchester. Tenders to 5th March.

HOUSES, *Leeds.*—One house and shop and six cottages adjoining. Plans at the Lamb Inn, Kirkgate, to 28th inst. No date.

HOUSE, *Clay Hill, Bushey, Herts.*—Alterations, additions, and repairs. Plans, &c., of Mr. Lavender, architect and surveyor, Watford. Tenders to noon, on 28th inst.

GARDENER'S HOUSE, *Ellonoastle, Aberdeenshire.*—Masons', carpenters', slaters', and plasterers' work. Plans, &c., with T. F. Jameson, Langley-cottage, Ellon. Tenders to 28th inst.

DWELLING HOUSE, *Priestwells, Parish of Insch, Aberdeenshire.*—Mason, carpenter, slater, and plaster work. Plans of overseer at the farm. Tenders to March 4.

STABLES AND COACH-HOUSE, *Strickenhouse, Aberdeenshire.*—Masons', wrights', carpenters', plasterers', slaters', and plumbers' work. Plans at same place. Tenders to March 1.

HOUSE, *Windsor.*—A house at Windsor, designed for dwellings for labourers' families. Plans, &c., of Wm. Towers, secretary to Windsor Royal Society, to whom tenders before the 1st March.

FARM HOUSE, *Sleaford, Lincolnshire.*—On Timberland Farm. Drawings, &c., at Mr. Payne's, Saxilby, near Lincoln, to whom tenders on March 2.

CHURCH, *Aldershot.*—For enlarging, &c., parish church, Aldershot, Hants. Plans, &c., up to evening of 19th inst. (to-morrow), at offices of Messrs. Eggar, architects, Farnham, Surrey. Tenders to Building Committee, care of Rev. J. Bennett, the parsonage, Aldershot, by 3 o'clock 1st March.

PLANS FOR A WORKHOUSE, *Blackburn.*—Workhouse, for 700 people, to cost £12,000; £50 for the best plans. Particulars, &c., from the clerk of the guardians, to whom plans on the 1st April,

DRAUGHTSMAN, *Birmingham.*—To make finished and detail drawings of railway carriages, &c. Letters to Messrs. J. Wright and Sons, Saltley Works, Birmingham.

ENGINEERS.—A thorough practical engineer, apply personally to G. Buchanan & Co., Colonial and Sugar Machinery Engineers, 25 Bucklersbury, E.C.

SECOND-HAND CONTRACTOR'S RAILS.—Flange pattern, 35 to 40 lbs. per yard, delivered at a port on south or west coast. Lawrie and Hagger, 33 Lombard-street, E.C.

PUMPS WANTED.—Cast iron flange-pipes, about 15 in diameter. B. T., Chadborn, Pinxton, near Alfreton, Derbyshire.

STATIONARY ENGINE, of 30-horse power, to drain a mine in Devon. James G. Smither, Falcon-court, 32 Fleet-street E.C.

TRAVELLER, to sell wire, rope, and colliery stores in mining districts. "N. X.," 26 Fleet-street.

LEAD SMELTER.—An under-manager. "V. D. R.," Post-office, Liverpool.

MINE CAPTAIN.—One who speaks Welsh, to take management of a copper-mine in Wales. "B. B.," 26 Fleet-street.

CLERK OF WORKS, *Wells.*—To superintend the construction of 2,600 yards of sewers in Wells. Salary, £2 per week, 3 months certain. Particulars from the town clerk, to whom offers on the 1st March.

PERMANENT CLERK OF WORKS.—Apply to Messrs. Beadel, Son, and Chancellor, architects, Chelmsford.

SURVEYOR AND DRAUGHTSMAN.—To "T. A. B.," Mrs. Jones, ironmonger, Mardol Head, Shrewsbury.

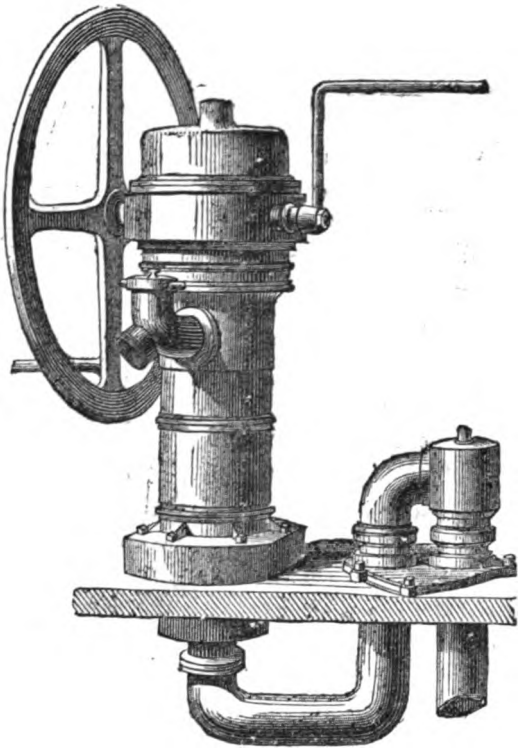
Under the Patronage of the Board of Admiralty.

SHIPS' PUMPS OF HER MAJESTY'S NAVY.

JOSIAH STONE,

Sole Manufacturer of DOWNTON'S well-known and much approved SHIPS' PUMPS, which have been used in preference to all others on board the vessels of Her Majesty's Navy, for upwards of thirty years, and have given the greatest satisfaction, effectually answering all the purposes required of any Ships' Pumps, and capable of throwing most powerful jets of water in case of fire.



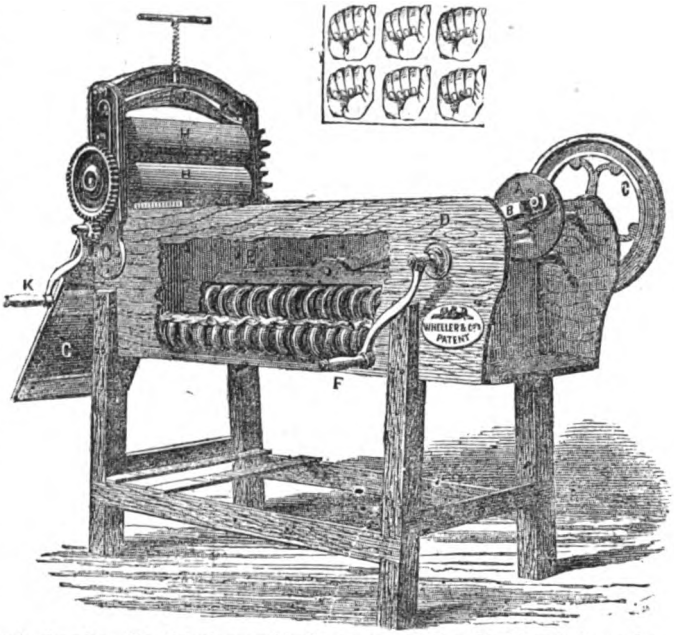
These Pumps have also been most extensively used on board merchant vessels, both at home and abroad, and have been supplied to the Royal Navies of France, Prussia, Holland, Russia, Spain, and Turkey. The Pumps are portable, as they may be easily removed from the ship and put to work in a boat alongside in a few minutes. Each pump is fitted with a large foot valve plate (which may be placed in any part of the vessel most convenient), and from which communication is made to any number of distinct compartments in the vessel. In case of any of these pipes fouling, the water, by an almost momentary attachment, may be forced from the Pump downwards, so as to clear all obstructions, preventing any possibility of stoppage. The valves are of the simplest description, and being faced with ordinary leather discs, the latter may be renewed in a few minutes by the most inexperienced hands. By the peculiar construction of these Pumps, a most perfect and uninterrupted flow of water may be maintained; so uniform as to be undistinguishable from that proceeding from a cistern. The Pumps are made of several sizes, those of 7, 9, and 12 inches bore being most generally used. They may, however, be ordered of any dimensions required, and may be fitted either with one or two fly wheels. A standard, &c., is also supplied with these Pumps, to enable them, when necessary, to be used as ordinary hand-lever pumps.

JOSIAH STONE, Engineer, Manufacturer of all descriptions of PUMPS and FIRE ENGINES for Land and Ships' Use; Brass and Iron Founder and Finisher, Nail and Rivet Maker, &c.

CONTRACTORS FOR FIRE-ENGINES, ETC., TO THE WAR DEPARTMENT,

RAILWAY STATION, DEPTFORD, AND 12 GARLICK HILL, CITY, E.C. (97)

T. WHEELER AND CO.'S
"OXONIAN KNUCKLE WASHING MACHINE."



THE Improvements in these New Inventions are the non-exposure of the user's hands to the dangerous parts of the Machine, and the rapidity with which the work is done. These Machines have neither bands or wheels passing on the outside, wherein lies the liability to accident. The rubbers are the truest representation of the knuckles or hand washing yet brought out; the compensating floating rubbers work at right angles, backward and forward, in the same manner as does the hands. These Machines can be supplied with rubbers that represent a person's hand in the action of rubbing; the knuckles, finger nails, and palm of the hand being truly modelled. They are capable of Washing Clothes of every description whatsoever, the largest bedding to the most delicate piece of muslin can be washed without breaking a single thread; in fact, such is the delicacy of the action of these Machines, that the paper you are now reading can be passed between the rubbers without sustaining any injury, at the same time being thoroughly effective in cleansing. The Patentees confidently recommend these Machines to the notice of Laundresses, Heads of Families, Hotels, Emigrants, &c. So simple is the action of this Machine, that a boy or girl of 10 or 12 years of age can work it; the only skill required is to soak the clothes one hour before placing them in the Machine, placing a portion of the clothes at the handle end of the Machine; laying on the rubbers a part of them; turn the handle, and the clothes will pass through between the rubbers to the opposite end, effecting a saving of at least 50 per cent.

Prices: Washing Machines, £1 6s., £2 6s., £3 6s., £4 10s., £5 15s.; Washing, Wringing, and Mangling, £8 £10 10s., £14 14s.—Full Instructions sent with every Machine. Testimonials or References sent on application.

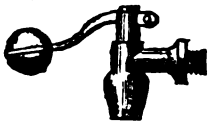
MANUFACTORY, ALBION WORKS, PARK END STREET, OXFORD (114)

TO BRASS-FOUNDERS, ENGINEERS, &c.

THE PATENT PLUMBAGO CRUCIBLE COMPANY having completed the enlargement of their premises, beg to call the attention of all users and shippers of Melting Pots to the great superiority of the PATENT CRUCIBLES, which have been used during the last three years by some of the largest melters in England and abroad. In addition to their capabilities of melting an average of from thirty-five to forty pourings; they are unaffected by change of temperature, never crack, but can be used till worn out, requiring only one annealing for several days' work, and become heated much more rapidly than ordinary pots, effecting thereby a saving of more than fifty per cent. in time, labour, fuel, and waste. The Patent Plumbago Crucible Company also manufacture and import clay crucibles, muffles, portable furnaces, sublimate pans and covers, glass-pots, all descriptions of fire-standing goods, and every requisite for the assayer and dentists. For Lists, Testimonials, &c., apply to Battersea Works, London, &c. (43

HIGH-PRESSURE VALVE-COCKS, LAMBERT'S PATENT.

Equilibrium Ball Valve. Cottage Closet Valve.



The Equilibrium Ball-Valve is simple and certain in its action, and is cheaper than the common cocks now in use.

The Cottage Valves are suitable for application to any kind of basin; and, as they shut against the pressure, no concussion in the pipes can possibly occur.

These cocks have been extensively and most successfully used in many towns, under continuous high pressure, varying from 100 to 350 feet; their efficiency and durability is, by experience, established.

THOMAS LAMBERT and SON,

Brass Founders, Short-street, New-cut, Lambeth. (80)

PUMPING MACHINERY.

GWYNNE AND Co., Engineers, London, manufacture and supply the following Machinery, of the most approved construction and with all the latest improvements:—Portable and Fixed Steam-Engines and Boilers of every description; Waterwheels, Windmills, Horse and Hand-power Machines; Pumping Machinery for the Supply of Towns, Cities, and Districts, and for the Irrigation of Coffee, Cotton, Indigo, Sugar-cane, and Rice Estates, for pumping out Coffer-dams, Canals, Dry Docks, Reservoirs, &c. They also manufacture and supply the Pumping and other Machinery for Paper, Pulp, and Fulling Mills, Breweries, Distilleries, Tanneries, Starch Works, Bleaching, Dyeing, and Calico Printing Works, Chemical Works, Silk, Cotton, and Flax Mills, and Manufactories in general. All Letters not paid will be refused. Illustrated Price Lists forwarded on receipt of Six Postage Stamps.—GWYNNE AND Co., Hydraulic and Mechanical Engineers, Essex-wharf, Strand, London.

For Exportation.—The above can be obtained through British Merchants, Shippers, and Colonial Agents. (24)

W. BLACKETT has in Stock a variety of Vertical and Horizontal Steam Engines, Boilers, and Engineers' Tools, ready for delivery on the shortest notice. Apply as above. (70)

THE PATENT CARVING WORKS.—(JORDAN'S PATENT.)—A considerable reduction in the cost of Wood Carving is effected by the aid of the Patented Machinery, as by it the work is roughed out with great accuracy and expedition (the cutters making 7,000 revolutions per minute), while the finishing of the more minute parts is carried out by hand labour, so that the result shows precisely the same amount of artistic excellence as if it had been executed entirely by hand.

The trade supplied with Carving in the rough, or finished.

COX & SON, Belvedere-road, Lambeth. (119)

WANTED TO PURCHASE, one of CANTELO'S INCUBATING MACHINES. Must be in good working order. A new one preferred. Address, with full particulars, A. Z., MRS. BARNETT'S, 47 Queen's Road, Brighton. (120)

"Everybody likes good Beer,
But everybody don't know where to get it."

WATER GAUGES—WATER GAUGES.—Sir,—We find your German Gauge Tube superior to any other, and strongly recommend it. We were compelled to abandon the use of our water gauge until applying your glass tube.

WILCOX and Co., Millwall Pottery Company.

These Tubes are superior to all others; being a clear white, no mistake can arise in working. Guaranteed to stand a pressure of 500 lb.

Extensively used on all the principal lines.

To be had only of E. MOORE, 55 Upper Marylebone-street, W.; and 72 Great Titchfield-street, W.

*** Price List of Gauge Fittings, &c., on application. (98)

BY HER MAJESTY'S ROYAL LETTERS PATENT.

PATENT SPHERICAL SELF-ADJUSTING BEARINGS, which do not heat in work. The advantages possessed by these Bearings are:—

1st. They are Self-adjusting; and, consequently, can be put down by the most ordinary Mechanic.

2nd. They are not liable to heat, even at high speeds.

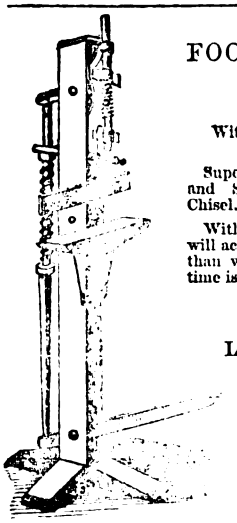
3rd. They remain constantly parellel to the Spindle; and, therefore, wear equally all across the Bearing.

4th. They require only a very small quantity of oil.

Engravings and Prices forwarded on application to the Patentees.

WALLIS & HASLAM,

Engineers and Iron Founders, North Hants Iron Works, Basingstoke. (121)



FOOT MORTISING MACHINES,

With set of Chisels, for £9.

Superior to any in use for Doors and Sashes, with self-reversing Chisel.

With this Machine the workman will acomplish one-third more work than with any other in use, as no time is lost in shifting the Chisel.

For Sale by

L. D. OWEN & CO.,

Importers of

WOOD-WORKING MACHINES,

192 Tottenham-court-road (101)

HALKETT'S GUIDEWAY STEAM AGRICULTURE will be Exhibited at Canning-place, Kensington Toll Gate, South of Kensington Gardens, on Wednesdays, the 9th, 16th, and 23rd of February, and to private view upon previous appointment. By this system, every operation of the Farm is performed by Steam Power, the land largely increased in value, and the cost of cultivation greatly reduced. A paper read before the Society of Arts, illustrations, &c., will be forwarded upon application to the Office, 80 Chancery-lane, W.C. (104)

THE LONDON

WARMING AND VENTILATING COMPANY,

(LIMITED,)

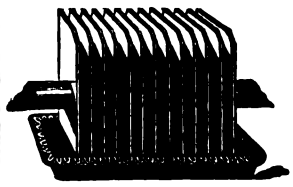
36 GREAT GEORGE STREET, Westminster, S.W.

(MANAGER—Mr. WOODCOCK.)

Churches, Greenhouses, Offices, and Buildings of every description warmed by means of a modification of the plan successfully used during the last five years by Mr. Goldsworthy Gurney in both Houses of Parliament.

Steam, Hot-water, Gas, and in open or enclosed fireplaces, Coal and Coke are equally available for the process.

The cost is less and the effect greater than that of any other known means.



The Horticulturist will find herein an instrument of new and important powers.

The apparatus may be seen in ST. PAUL'S CATHEDRAL, the various offices of the "Department of Science and Art," and in many churches and other buildings.

Particulars and Testimonials forwarded on application.

(12)

PIERCE'S

UNRIVALLED

PYRO-PNEUMATIC FIRE-LUMP WARMING AND VENTILATING STOVE GRATES,

WITH the cheerful, open fire, producing healthful warmth, with continuous Self-acting Ventilation, for Churches, Schools, Public Buildings, Banking Houses, &c. These Grates are manufactured solely by PIERCE, the Inventor, for which he received the Prize Medals of London in 1851, and of Paris in 1855.

PRICE, from £7 10s.

ILLUSTRATED CATALOGUE, with Prices and Estimates for Work, furnished on application to the Inventor and Sole Manufacturer.

Also his

IMPROVED COTTAGER'S GRATE,

For Warming Two Rooms with only One Fire. Prices, 30s. and 35s.

PIERCE, No. 5 JERMYN STREET, REGENT STREET.

(111)

VENTILATION WITHOUT FLUES.

KUKLA'S PATENT STOVES,

At 18s., 25s., and 50s.

KUKLA'S newly-invented Deflagrator—the first and only perfect GAS STOVE. Guaranteed to burn without flue—without dust, smell or smoke, producing a great and pure heat with the least expenditure of Gas.—*Vide Society of Arts' Journal.*

Patronised by the English and French Government.

Scientific in Principle,
Simple in Construction,
Healthy and efficient in use.

The Deflagrator Stove is cheap, portable, and suited for every situation; and from the principle on which it is constructed (viz., expanding to a sixfold volume the gas used) is capable of warming any given space more quickly and more thoroughly than any other means: while its addition forms a sure remedy for any ill-warmed or ill-ventilated apartments.

The 25s. Deflagrator warms a room of 2,000 cubic feet at a cost of 3d. per day.

The 50s. Deflagrator warms 5 to 6,000 cubic feet at a cost of 6d. per day (twelve hours).

Also, the Greenhouse Stove at 18s.

Patentee and sole Manufacturer, F. X. KUKLA, 194 Pentonville-road, London.

Country orders promptly attended to. Carriage free to any Railway in London.

Post-office Orders should be made payable to FRANCIS XAVIER KUKLA, General Office.

N.B.—Every Stove separately tested before sent out.

The New GAS COOKING STOVE for 10 persons, price £3.

(103)

CLAYTON, SHUTTLEWORTH, AND CO.,

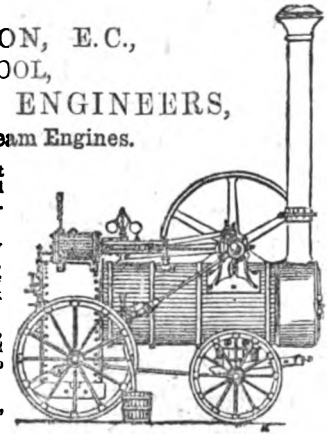
OF LINCOLN,

78 LOMBARD STREET, LONDON, E.C.,

AND 36 DALE STREET, LIVERPOOL,

AGRICULTURAL AND GENERAL ENGINEERS,

And Manufacturers of Portable and Fixed Steam Engines.



Combined Threshing Machines, which dress the corn ready for market at one operation. Grinding Mills, Saw Benches, Pumps for Irrigation and Mining purposes, with all necessary gearing for being driven by steam power. Full particulars and estimates given on application to the above address.

C. S. and Co.'s PORTABLE STEAM ENGINES are adapted for every purpose to which steam-power can be applied. When intended for winding, they are fitted with reversible link motion and winding gear. They are easy of removal, as may be seen by the engraving, and can be set to work immediately on arrival.

C. S. and Co. are now doing an extensive foreign and colonial business, and are prepared to send off engines and machinery of the before-mentioned kinds in a few days from the date of order. They would also call attention to the important *reduction in prices* made for the new year.

For Exportation.—The above can be obtained through British Merchants, Shippers, and Colonial Agents. (23)

IMPORTANT TO MANUFACTURERS, MILL OWNERS, &c.

GUTTA PERCHA MILL BANDS.

THE GUTTA PERCHA COMPANY beg to state that the increasing demand for the Gutta Percha Strapping for Driving-bands, Lathe-straps, &c., fully justifies the strong recommendations they have everywhere received.

Their durability and strength—permanent contractability and uniformity of substance—their non-susceptibility of injury from contact with oils, grease, acids, alkalies, or water—and the facility with which the only joint required can be made in bands of from 200 to 300 feet long—render them superior to leather for almost all working purposes, and decidedly more economical.

TESTIMONIALS.

IMPORTANT ANNUAL SAVING.

From TRUMAN, HANBURY, BUXTON, & Co., Brewery, London.

"In reply to your inquiry, we have much pleasure in bearing our testimony to the advantages, both as regards economy and saving of time, effected by the use of your Patent Gutta Percha Bands in lieu of Leather Straps. The stoppage of one portion of our works through the failing of the leather strap used to be of daily occurrence—but with this annoyance we are now never troubled. We have had these straps in operation for nearly three years, and are assured by our Engineer that *they effect a saving to us of at least* THIRTY POUNDS *a year.*"

From JAMES ABERNETHY & Co., Fury Hill Foundry Aberdeen.

"We have now had Gutta Percha Bands working here *for three years.* One of them has been driving the fan blast for our smith's shop for all that time, and for anything we see, may drive it as long again. The speed of the fan is but 1,200 per minute. We have used them with complete satisfaction, driving circular saws, and in some cases where leather bands would have been quite inapplicable from damp. We have uniformly endeavoured to have the drums and pulleys so proportioned to the strain, as that there is no chance of the band slipping; and with this precaution, and taking care in using *cross bands that they do not rub,* we are quite satisfied that they are superior in every respect to leather—stronger at the same weight, and keeping quite straight in working—requiring no lacings, and very seldom any repairs."

WATER POISONED BY LEADEN PIPES.

The above engraving represents accurately a section of a leaden pipe, which was employed for a short time in conveying water from a well on the grounds of Mr. Dick, of Bonchurch, Isle of Wight.

POISONED WATER PREVENTABLE

BY THE USE OF GUTTA PERCHA TUBING.

The Gutta Percha Company have been favoured with the following letter,

From Dr. MURRAY, Hull.

"It is impossible to conceive of anything more injurious or destructive to the health of the community than the use of *leaden pipes* for the conveyance of water. The poisonous salts of lead thereby communicated are most insidious and subtle. I hail with gratitude the substitution of Gutta Percha Tubing. I have had the leaden pipe of my own house removed, and its place supplied with one of Gutta Percha Tubing. Nothing can be better. I have also recommended it to others, who have adopted the expedient."

A variety of Gutta Percha Articles, such as Mill Bands, Tubing, Sheet, Soles, Pump Buckets, Bosses, Union Joints, Bottles, Bowls, Flasks, Curtain and Cornice Rings, Solid Frames, Galvanic Batteries, &c., &c.

SOCIETY OF ARTS.—The Eleventh Annual Exhibition of Inventions will open on the 25th day of April, 1859. The days fixed for receiving articles intended for exhibition are Thursday the 7th, Friday the 8th, and Saturday the 9th April. No charge is made for space, and the Exhibition is Free.

Intending exhibitors should communicate at once with the Secretary. By order,

P. LE NEVE FOSTER,
Society House, John-street, Adelphi, 1st March, 1859. Secretary. (162)

GLADSTONE & Co., CONTRACTORS and ENGINEERS.
2 John-Street, Minories, London, E.C.,
Are prepared to ESTIMATE FOR and CONSTRUCT BRIDGES, PIERS, JETTIES, &c., in Iron, Wood, or Stone. Also to supply Cranes, Girders, Turntables, and Railway Work and Plant generally. (56)

STEAM ENGINES FOR SALE.
PORTABLE STEAM ENGINES, from 6 to 12 horse power,
STATIONARY STEAM ENGINES, from 4 to 50 horse power,
TUBULAR BOILERS, from 4 to 50 horse power,
CORNISH BOILERS, from 4 to 50 horse power,
Are in hand, and can be despatched on eight days' notice. Prices moderate. Workmanship and Material of the best description.
Apply to R. THOMPSON & Co., St. Leonard's Iron Works, Edinburgh. (60)

BRICKS.
TO BE LET, with immediate possession, in consequence of the death of the proprietor, J. M. Paine, the DIPPENHALL SILICA FACTORY, erected for the purpose of making improved Fire Bricks, Building Bricks, Paving Tiles, &c., &c., from the Soluble Silica Rock.
Apply to view the Buildings and Bricks to G. H. Ogston, Esq., Resident Manager, Dippenhall, Farnham, Surrey; and for terms, to Messrs. Nicholls and Potter, Solicitors, Farnham. (125)

HART & SON, MALLEABLE IRON FOUNDERS, 4 Vine-street, York-road, Lambeth.
Orders for Malleable Iron Castings executed within a week. (77)

ENGINEERING AND MECHANICAL DRAWING CLASSES.—Instruction given in Engineering and Mechanical Drawing, comprising the preparation of plans, elevations, and sections of marine and locomotive engines, with the detail and working drawings; also the method of delineating screws, bevel wheels, &c.; orthographical projection, and tinting, shading, and colouring taught.—For prospectuses of the Day and Evening Classes apply to Mr. T. J. HILL, at the offices, 15, Old-street, City-road. (73)

TO MARINE ENGINEERS, OR SHIP-BUILDERS.
THE PROPRIETOR of a VALUABLE PATENT for Double-expansive Marine Engines (by which great economy of space and fuel is obtained) is desirous of entering into arrangements with a respectable firm for the construction of the same. An adequate portion of the patent-right would be assigned by the advertiser to any firm taking the matter up; and he would render all assistance in his power, either in London or elsewhere, amongst ship-owners (to many of whom he is well known), in obtaining contracts, &c. Unexceptionable references given. Address C. E., MECHANICS' MAGAZINE Office, 166, Fleet-street. (76

INDIA-RUBBER VALVES FOR STEAM ENGINES, PUMP PACKING, &c.—Explanatory Drawings and Information as to the best modes of fitting and arranging the above, and all other Mechanical Applications of VULCANISED INDIA-RUBBER, are furnished post-free by
CHARLES MACINTOSH & Co., Patentees,
Cambridge-st., Manchester, and 3 Cannon-st. West, London.
MANUFACTORY and DEPÔT, Cambridge-st., Manchester.
GENERAL WAREHOUSE, 3 Cannon-street West, London, E.C.—C. M. and Co.'s only Establishments. (139)

TO BRASS FOUNDERS.
TO BE SOLD, the Patent-right of a New and Highly-approved EQUILIBRIUM WATER COCK or VALVE, suitable for Steam Boiler Feed Pipes, or any cases where the valve is required to be opened against pressure.
Address H., MECHANICS' MAGAZINE Office, 166 Fleet-st., where a Drawing may be seen. (151)

STEAM ENGINES.
FOR SALE, a superior HIGH PRESSURE HORIZONTAL STEAM ENGINE of 6-horse power, 8-inch cylinder, and 1-foot 6-inch stroke. One of 8-horse power, 10-inch cylinder, and 1-foot 6-inch stroke. One of 10-horse power, 12-inch cylinder, and 2-feet stroke. Two of 14-horse power, 14-inch cylinders, and 2-feet stroke; and one of 30-horse power, 20-inch cylinder, and 3-feet stroke.
Apply to Messrs. PAGE and CAMERON, 64 Old Broad Street, E. C., London. (124)

ENGINEERING BUSINESS FOR SALE.
OWING to the continued ill health of the Proprietor, the first-class business of an Engineer and Crane and Block Maker is offered for sale. It has been established in the Metropolis for nearly 30 years, and has enjoyed extensive patronage amongst Brewers, Manufacturers, Warehousemen, and others, in and about London; the business done amounting to nearly £8,000 per annum. About £3,300 would be required, (part of which, however, may remain for any reasonable time on good security,) which is the bare value of the tools, patterns, and stock in trade. The premises, including good dwelling-house, very conveniently situated, and capable of accommodating from 60 to 70 hands, are held upon a long lease, at an extraordinary low rental, not exceeding £100 per annum, taxes included. Many of the tools are nearly new, and of the best construction. The present proprietor, who relinquishes the business solely on account of ill health, would give every assistance in his power to those succeeding him; and as his foreman, who has been with him for nearly ten years, is thoroughly acquainted with the practical parts of the business, any gentleman desirous of commencing as a manufacturing engineer would find the present a very favourable opportunity. As all accounts have been, for many years past, collected quarterly, a very small amount, say £800, would suffice as working capital. Full particulars may be obtained by application to E. E. ALLEN, Esq., MECHANICS' MAGAZINE Office, 166 Fleet Street, E.C. (130)

TO COMMERCIAL TRAVELLERS.
WANTED, a Gentleman well-acquainted with Ironmongers, Upholsterers, Coopers, &c., to Travel on Commission.
Address, A. Z., MECHANICS' MAGAZINE Office, 166 Fleet-street. (161)

TO ENGINEERS, INVENTORS, AND OTHERS.
A PRACTICAL ENGINEER of long standing prepares Original Drawings, Copies, and Tracings. Advice and Assistance given to Inventors in working out their Plans. Pupils taught privately. Terms moderate.
Apply to J. J., 171 Strand. (138)

A VALUABLE PATENT to be DISPOSED OF.—The Patentee will either dispose of the Patent or grant Licences to any party wishing to manufacture, or would join a person with capital to carry out the Patent.
Address, A. Z., MECHANICS' MAGAZINE Office, 166 Fleet-street. (163)

TO ENGINEERS, ARCHITECTS, PATENT AGENTS, &c.
PHOTOGRAPHS OF THE HIGHEST CLASS and of any size, taken and reproduced at a most moderate rate of charge. Reproductions of faultless accuracy, of Machinery, Models, Drawings, &c. Orders attended to in town and country. Estimates forwarded.
SPENCER, READ, & Co., 4 Agar-street, Strand. W.C. (90)

ENORMOUS REDUCTION in the Cost of STEAM POWER to Railway Companies, Steam Ship Proprietors, and Manufacturers.
A saving of fuel equal to one-third of the entire consumption is effected by the use of the "PATENT SPIRAL HEAT DIFFUSERS," which are exceedingly simple, and do not require any alteration in the existing arrangement of Boilers at present in use for their application. They can be fitted in a few hours at a small cost. The Patentees are prepared to guarantee the results stated, and to accept for Royalty a part of the value of fuel saved by the use of the Apparatus.
Further information may be had on application to GWYNNE and CO., Engineers, Essex-street Wharves, Strand, London. (167)

CHUBB'S LOCKS, FIREPROOF SAFES, CASH AND DEED BOXES.
Complete lists of sizes and prices may be had on application.
CHUBB AND SON,
57 ST. PAUL'S CHURCHYARD, LONDON;
28 Lord-street, Liverpool; 16 Market-place, Manchester, and Wolverhampton. (4)

FIRE BRICKS.—THE FARNHAM INDESTRUCTIBLE SILICIOUS FIRE BRICKS have been greatly REDUCED in PRICE, and will be delivered at the Nine Elms Station, London, at 90s. per 1,000.—Address, G. H. OGSTON, J. M., Paine's Silica Works, Farnham, Surrey. (35)

ARTESIAN WELLS, BORING TOOLS, PUMPS, &c. Engineers, Architects, Surveyors, Builders or others requiring a good supply of Water may have any quantity procured by W. SPELLER, 14 York-street, Blackfriars'-road, London, where may be had any quantity of Tools for Sinking or Boring, from 2 to 20 inches diameter, and from 100 to 2,000 feet depth; also Men and Tools to bore for Railroads, Minerals, &c., in any part of the world. Boring Tools and suitable Pipes for exportation, with full instructions for their use.
Builders, Contractors, Brickmakers, Barge and Ship Builders, and others, can be supplied with Wrought or Cast Iron Pumps, Double or Single, for excavation of Deep Wells, from 3 to 14 inches in the bore, and from 6 to 130 feet in length, to work by Hand or Steam Power.
Hot-water Apparatus for Conservatories, &c., on the most economical and improved principles.
Also Manufactory for Captain John Grant's much improved Cooking Apparatus. (11)

AT SUFFELL'S, 132 Long-acre, London, W.C., every Instrument suitable for Engineers, Contractors, Surveyors, Architects, Draftsmen, &c., to be had second hand at very reduced prices, by the most esteemed makers, consisting of Theodolites, Levels, Circumferentors, Sextants, Compasses, Protractors, Station Pointers, Aeygraphs, Pentagraphs, Telescopes, Microscopes, Cases of Drawing Instruments, &c.; Rules, Scales, Chains, Levelling Staves, and Measures of all nations. Every Instrument warranted. (169)

SCOTT'S
PATENT GRASS SEED SEPARATOR,

which entirely extracts the Seeds of "COUCH," "TWITCH," "SPEAR," or "HAIR" GRASS, and other impurities from

PERENNIAL AND ITALIAN RYE-GRASS, &c.,

AND

SCOTT'S PATENT CARROT SEED BEARDING

AND

CLOVER AND TREFOIL MILLING OR DRAWING MACHINE,

which effectually removes the beard from Carrot Seed, rendering it fit for sowing with facility by drill or otherwise, and by the separation of abortive or diseased grains vastly increases its vegetative per centage. By a slight modification it is applicable to the other purposes before mentioned.

These Machines were admittedly the most novel, and, at the same time, the most useful and important to the Farmer of any exhibited at the late SMITHFIELD CLUB SHOW.

They may be seen at work at the Establishment of the Manufacturer,

Mr. T. MIDDLETON, Engineer, Southwark.

Communications to be sent to the Patentee, J. SCOTT, 111 Drummond Street, Euston Square, London, N.W. (48.)

TO STEAM SHIP OWNERS, ENGINEERS, AND OTHERS.

How's Patent Steam Engine Counters, can be read at sight.

These Counters register the number of revolutions made by an engine or other mechanism. They may be used for ascertaining the duty of Pumping Engines and Water-wheels; the revolutions on board a steam-vessel; to calculate the slip of the propeller; and in a locomotive to test the slip of the wheels.

How's Patent Salinometer, for Steam Boilers using Salt Water.

By these, the density of the water in the Boiler is at all times accurately shown, and a saving of boiler and fuel is effected. They are adopted by the Admiralty, the Honorable Trinity Corporation, and others. Copies of Testimonials from Messrs. Penn, Messrs. Maudslay, and others, will be forwarded on application.

How's Engine-Room Telegraph, for communicating between Captain and Engineer.

Society of Arts Prize Medal, 1855.

is a Mechanical Telegraph, and by its peculiar construction, error or misunderstanding is rendered impossible. It is now extensively adopted, and gives great satisfaction.

How's Patent Fresh Water Apparatus for Ships' Use,

This apparatus is designed for the distillation of Fresh from Salt Water; and on long voyages, and where the supply of water is scanty, it will be found invaluable. Testimonials may be seen.

Patent Steam Pump and Fire-Engine for Ships' Use.

This Steam-pump occupies but a small space; works perfectly noiselessly, and throws an immense volume of water An Illustrated Circular of Fresh Water Apparatus and Steam-pump combined, free on application.

How's Patent Machine for Cutting Bolts, Rods, Spindles, Wire, &c.

Simple in construction, inexpensive, occupies but little space, and will not easily get out of order.

A Pamphlet Illustrative of the above, sent free by post, on application to

A. P. HOW, ENGINEER,

81 MARK LANE, LONDON.

EVERY DESCRIPTION OF ENGINEERS' TOOLS, ENGINE ROOM STORES, &c., &c., SUPPLIED. (89)

TO ENGINEERS, MILLWRIGHTS, MACHINISTS, &c.

VULCANIZED INDIA-RUBBER

In any of the following forms, of any size, or to Working Drawings for all MECHANICAL *purposes:—*

WASHERS for Steam and Gas Joints.
VALVES for Marine and other Steam Engines.
ENGINE-PACKING (Elastic).
PUMP-BUCKETS ,,
HOSE-PIPES.
GAS-TUBING.
SUCTION HOSE.
FIRE ENGINE AND FACTORY HOSE.
WATERPROOF CART, VAN, AND WAGGON COVERS.
MACHINE AND MILL-BANDS fo Driving all kinds of Machinery.
RAILWAY BUFFER SPRINGS.
BALL VALVES.
PUMP-PACKING (Rings or Rope).
WHEEL-TIRES (Noiseless).

N.B.—A Large Stock of the above always on hand, and any modification made to order.

Please address all communications to the Manufactory,

JAMES LYNE HANCOCK, VULCANIZED INDIA-RUBBER WORKS,
Goswell Road, London, E.C. (85)

By Her Majesty's Royal Letters Patent.

E. DENCH,

KING'S ROAD, CHELSEA, AND HAMPSTEAD ROAD, &c., Patentee and Sole Manufacturer of

ON THE MODIFICATIONS WHICH THE SHIPS OF THE ROYAL NAVY HAVE UNDERGONE DURING THE PRESENT CENTURY, in respect to Dimensions, Form, Means of Propulsion, and Powers of Attack and Defence: together with a Letter on the Steam Navy of France. By Mr. E. J. REED, late of Her Majesty's Dockyard, Portsmouth; one of the Editors of the MECHANICS' MAGAZINE. (Republished by permission of the Council of the Society of Arts.)

ROBERTSON, BROOMAN, AND CO., MECHANICS' MAGAZINE and Patent Offices, 166 Fleet-st., London. (159)

Now Ready,

EVENINGS AT THE MICROSCOPE. By PHILIP HENRY GOSSE, F.R.S. Post 8vo., cloth. With numerous Engravings. Price Eight Shillings.

In this work the Author has described in familiar, but at the same time accurate language, the form, structure, and appearance of a large number of objects fit for Microscopic study, taken from the whole range of the Animal world. Many notes are interspersed on the use of accessory instruments, on manipulation, and on the preparation of specimens; and the whole forms a fit Introduction to Microscopic Zoology.

The observations are almost entirely original, and they are copiously illustrated by Engravings, mostly drawn upon wood, *direct from the life*, by the Author himself.

BRAY'S TRACTION ENGINE COMPANY (Limited).—CAPITAL, £100,000, in 20,000 Shares of £5 each.

The important invention of Mr. Bray having demonstrated the practicability of drawing carts and wagons in public thoroughfares by steam power, the above Company has been formed for supplying the public with Traction Engines of such description as shall, with greatly diminished working expenses and power of more rapid transit, take the place of horse teams in the traffic of goods on COMMON ROADS—more particularly in those districts not possessing railroad accommodation, and between Railway Termini.

Hitherto the only obstacle which has prevented the adoption of steam power for such work has been the fact, that, until the construction of Mr. Bray's Traction Engine, not one of those previously offered to the public fulfilled the conditions indispensable to success, namely, simplicity of construction and economy in working, ability to follow with ease the laws of the road, and to turn and stop suddenly; ability to ascend the steepest hills, and descend them without risk; ability to travel upon COMMON ROADS without the assistance of an endless railway, a tramway, or any special bearing surface beyond that of an ordinary road; ability to perform hard work without being liable to get out of order; and possessing driving wheels which cannot slip upon any description of ground.

The heavy work which these Engines have executed, and the severe tests to which they have been applied in Her Majesty's Dockyard, Woolwich, and other places, with the most satisfactory results, give indisputable proofs that those mechanical arrangements necessary to the commercial success of a common road engine have now been attained.

The consequence of thus superseding horse power by steam will be a reduction in the cost of moving goods upon COMMON ROADS corresponding with the savings made in the cost of passenger and goods traffic by the railway locomotive.

Hence the use of these Traction Engines must shortly become general, and a large and profitable business to the Company will be the result.

Forms of application for shares, and detail prospectuses explaining the constitution of the Company and the commercial prospects of the undertaking, may be had at the Company's offices, 12 Pall Mall East, London, S.W.

By order of the Board,
C. A. HANSON, Secretary.
(171)

BRAY'S TRACTION ENGINE COMPANY (Limited) are PREPARED to enter into CONTRACTS for SUPPLYING ENGINES constructed to DRAW LARGE or SMALL LOADS upon COMMON ROADS.—Apply to Mr. C. A. HANSON, Company's Offices, 12 Pall Mall East, London. (172)

STEAM BOILER ASSURANCE COMPANY, MARKET-STREET, MANCHESTER.—Registered pursuant to Act 7 and 8 Vict., cap. 110—Capital £50,000, with power to increase to £100,000, in shares of £10 each.

AUDITORS:

Messrs. Child, Fitzgerald, and Taylor, 63 King-street, Manchester.
Mr. C. H. Minchin, 59 King-street, Manchester.

CHIEF ENGINEER—R. B. Longridge.

SECRETARY—Jonathan Cox.

This Company has been established to supply a recognised want existing in an important section of the mercantile community, by applying the principles of insurance, combined with efficient inspection, to steam boilers.

The numerous explosions of steam boilers that have taken place during the last four years have proved the necessity of scientific supervision, which if not voluntarily adopted by the employers of steam power, will doubtless be eventually forced upon them by Government interference.

It being evidently the interest of the Company to prevent accidents to the boilers insured by them, they have been careful to select the highest engineering talent, and such as is known to be specially valuable in this particular department of the profession. Should such accidents, however, unfortunately occur, the insured will not suffer pecuniary loss in addition to other inconvenience.

The Company appeal confidently for the support of all employers of steam boilers, not only on the ground of the wisdom and prudence that induce the careful manufacturer to insure his property generally, but on the still higher one of assisting in the prevention of the fearful sacrifices of human life that are almost sure to be consequent upon accidents of this nature.

The Company insure boilers of every description, and also any damage arising to buildings and property from their explosion; exclusive, however, of fire risks, and destruction of ships by marine boiler explosions.

They also assure the lives of workmen and others to a limited amount per head.

Where boilers sustain injury from accidental causes, though explosions may not actually ensue, the damage will be made good, or the amount thereof paid, by the Assurance Company, according to valuation.

The owners of boilers who may not wish to insure their full value, are at liberty to take policies for not less than £100 on each separate boiler, thus securing inspection and an assurance of £100 on each boiler, at a premium varying from 15s. upwards.

A "Registration of Steam Boilers" has also been established, on the principle adopted at Lloyd's in the case of ships. New boilers are examined and tested by the officers of the Company previous to leaving the works of the makers, and certificates issued according to their classification.

The Inspectors will, if required, indicate the engines of the insured, and advice will be given by the chief engineer of the Company in all matters relating to the economical use of steam power.

LIFE.

Enginemen, Stokers, and all persons attendant upon Boilers or Engines.—To insure £100 on each life lost by boiler explosion, £1 per annum, inclusive of Government duty.

Workpeople employed in mills or works generally (exclusive of those above specified).—To insure £50 on each life lost by boiler explosion, one shilling per head per annum on the whole number employed in such mills or works, inclusive of Government duty.

Cases of extra risk taken at increased premiums.

BUILDINGS AND OTHER PROPERTY.

Buildings, machinery, &c., are insured against damage from boiler explosions, at specific rates, from 1s. to 7s. per cent., according to Surveyor's report.

By order,
J. COX, Secretary. (173)

TO WIRE ROPE MAKERS.—ARCHIBALD SMITH is now prepared to GRANT LICENCES for the use of his PATENT ROPE MACHINERY, guaranteed to work at six times the speed of any other, and to save upwards of fifty per cent. in the cost of making. It is used by the most eminent makers, and was also in the manufacture of the Atlantic Cable.—Apply to 69 Princes-street, Leicester-square, W. (8)

REMARKS.—We are not yet able to report any decided improvement in the demand for Metals, the prices of which are almost without alteration since last week.

LAWRIE AND HAGGER, Metal Brokers.

33 Lombard-street, E.C.

METAL AND COAL TRADES, &c.

[FROM OUR OWN CORRESPONDENT.]

Board of Trade Returns for January—South Staffordshire Iron Trade—A Bankrupt Ironmaster—South Wales Trade—Glasgow Pig Iron Trade—Metal and Coal Trades in Derbyshire, Yorkshire, and Lancashire—Birmingham and Wolverhampton Trades—Prices of Metals in Liverpool—Steam Shipping Trade—Trade at Huddersfield and Leeds—Coal Trade, and the Colliers' Petition for a Nine Hours' Bill.

THE number of Trade Returns for January show that in certain descriptions of iron exports, this year hitherto contrasts unfavourably with that of 1857. The opposite, however, obtains in regard to wrought iron, and copper, and brass. We extract the following figures :—

Month of January.

	1857.	1858.	1859.
Pig iron	£57,924	£42,353	£34,820
Bar, bolt, and rod iron, (exclusive of railway iron)	178,807	96,528	173,321
Railway iron	227,189	205,302	189,168
Wire	17,132	17,082	16,789
Cast-iron	65,596	58,894	46,715
Wrought-iron	185,730	147,759	187,339
Steel, unwrought	59,247	22,892	56,183
Copper, unwrought.....	38,543	19,067	94,078
„ sheets and nails, including yellow metal	146,463	106,281	129,810
„ wrought of other sorts	21,112	32,083	19,500
Brass.....	7,698	11,105	17,004
Tin, unwrought.....	32,551	23,559	22,093
„ plates.....	100,202	46,220	90,627
Coals and Culm	177,957	153,722	156,426
Machinery (steam-engines)	76,938	82,070	45,334
„ other sorts	116,649	157,752	140,119

Of this, France, who took steam-engines to the value of £12,146 in 1857, took only £649 worth in 1859. Spain nearly doubled its exports in January this year, and of "other lots" took upwards of five-fold more than in 1857. The augmentation of wrought-iron took place chiefly in the exports to India, which were more than doubled this year.

The South Staffordshire Iron Trade has not improved in the past week. On Change at Wolverhampton, yesterday, the uncertainty upon the vital question of peace or war, was acknowledged on all hands to be the secret of the prevailing quietude. This keeps back the specifications of many orders given out at the commencement of the quarter. Manufactured iron is going to Liverpool and Manchester from houses where there is but little floating capital, at prices very much below those of the first-class house, and considerably under the general rates of the district. Pigs are offering at the prices current before the rise just preceding last quarter day. The fall will continue if war should look imminent, but stop if a rupture should cease to be apprehended. Russia is in the market for rails and plates. Native iron stone realizes from 15s. to 17s. per ton.

Mr. W. T. Riley, ironmaster, of Wolverhampton, has obtained a third-class certificate in the Birmingham Bankruptcy Court, suspended for three months with protection. Mr. Commissioner Sanders strongly censured the neglect of the bankrupt to keep proper books.

In the South Wales district, it is stated that most of the large works are pretty well supplied with orders, and that a steady inquiry exists for iron of all descriptions. Railway iron is being sent away in large quantities to the Continent, the demand both from France and Russia being good.

In the Glasgow pig iron market on Tuesday, the following were the quotations :—No. 1, 50s. 3d. to 50s. 6d. ; Mixed Nos., warrants, 51s. to 51s. 3d. ; Mixed Nos., maker's iron, 50s. 3d. to 50s. 6d. ; No. 3, 50s. 3d. to 50s. 6d. Market quiet and steady. Shipped this week, 8,000 tons ; corresponding week last year, 11,060 tons. Under date Feb. 25, Messrs. Shaw and Thomson write :—"The course of the Scotch pig iron market during the past month has been an almost uninterrupted decline. The price on the 1st instant was 53s. per ton, and to-day there are sellers of mixed numbers, warrants, at 51s. 3d. per ton, and buyers offer 51s. per ton. The fall is chiefly attributable to uncertainty of the result of the present continental difficulties ; but the continued accumulation of stock and small shipments also tends to make holders realise. The shipments last month were 30,931 tons against 37,075 tons same month last year."

In the district embracing Derbyshire, Yorkshire, and Lancashire, the reports of the position and prospects of the iron trade are highly satisfactory, and present indications of a good trade for a considerable time, unless disturbed by the political aspect of affairs on the Continent. The orders from America are now increasing, and occasioning a better state of things in the steel trade at Sheffield, which is rapidly improving in consequence. The inquiry for all descriptions of merchant iron is steady, and gradually improving, and most of the works are in full operation.

The general hardware trades of Birmingham, Wolverhampton, and their districts, are steady. Expectations entertained at the end of the Christmas quarter have not been realised. Consequently, some little disappointment is being expressed ; but there is not much unemployed labour.

In Liverpool, on Saturday, tin-plates were in moderate demand, and purchases could be made at £1 11s. 6d. to £1 14s. per box for charcoal I. C., and £1 5s. to £1 7s. 6d. for coke I. C. Copper : £112 10s. per ton for British cake and tile, and 12½d. per lb. for copper sheathing. Lead : a good business was doing in pig, which is worth £22 5s. to £22 10s. ; sheet unaltered at £22 15s. to £23 per ton.

Respecting the steam shipping trade, Messrs. Alfred Brett and Co. say :—"We cannot report of much activity in steam shipping affairs. A fair extent of inquiry certainly exists for steamers of various sizes ; but an impetus is required that can only be imparted by a more favourable political aspect. For steamers of the largest class there is a remarkable want of remunerative employment, which naturally affects the value of this description of property—a considerable amount of which at present remains idle in port. Screw steamers of a handy size continue in moderate request, and several could just now be advantageously placed on charter. The building establishments remain still short of orders, as very few ships have been arranged for ; in February several important contracts are, however, understood to be in prospect. Sales of several paddle-wheel and screw steamers have taken place during the past month, and we still experience inquiry for useful vessels of these descriptions. As the season advances, and the hoped-for assurance of peace becomes more certain, we may reasonably anticipate increased and general improvement.

Tuesdays reports from Huddersfield and Leeds are dissimilar. In the former town matters are decidedly improving, whilst in Leeds the uncertainty in the immediate course of home and foreign politics has exercised a marked depressing influence upon both the foreign and home divisions of the trade.

The coal trade of the country generally is in a state of quiet prosperity. The miners, however, are not settled ; and owing to their want of information upon the exact condition of trade, are some of them both in the north of England and in South Staffordshire making faint efforts to procure an increase of wages. The movement, however, is premature, and has been successful only in exceptional local instances. The men have, however, a much more important matter under hand. They are about to make a vigorous effort to get from Parliament a Nine Hours' Miners' Bill.

LIST OF MISCELLANEOUS TENDERS INVITED, AND ENGAGEMENTS OPEN.

The tenders and vacancies which appear in this weekly list are not repeated in succeeding numbers.

WIDENING AND IMPROVING TURNPIKE ROADS, *at Penn and Sharcshill.*—Plans, &c., of Mr. Henry Beckett, surveyor, Wolverhampton, after 28th inst. Tenders on March 10th to Surveyor's office, Church-street, Wolverhampton.

INDEPENDENT CHAPEL, *Bridport.*—Plans, &c., at Mr. R. Swayne's, East-street, Bridport. Information of Messrs. Poulton and Woodman, architects, Reading. Tenders to March 11.

TOWN HALL, *Dudley.*—Extension of County Police Station, erection of residence for superintendent, and sixteen dwellings for police constables. Drawings of the Superintendent. Further particulars of Mr. Henry Lowe, jun., County Surveyor, 17 Foregate-st., Worcester. Tenders to March 19.

TWELVE ALMSHOUSES AND OFFICES, *Cambridge.*—For Royal Albert Benevolent Society. Drawings, &c., of the Secretary, Mr. T. P. Clayton, 23 Trumpington-street, Cambridge. Lithographed quantities, &c., of the architect, Mr. F. Peck, Maidstone. Tenders to the Secretary, on March 8.

FREE NEW GRAMMAR SCHOOL, *Stourbridge.*—Plans, &c., of Messrs. Freer and Perry, Solicitors, Stourbridge. Tenders by 19th March.

ALTERATIONS TO SHOREDITCH WORKHOUSE.—Particulars from Mr. J. H. Jones, architect, the Tower, Dalston. Tenders at the Workhouse at noon, March 12.

NATIONAL SCHOOL AND MASTER'S RESIDENCE, *Brewood.*—Plans at office of Edw. Banks, Esq., Clarence-street, Wolverhampton. Tenders 15th March, to Rev. H. E. Gedge, Brewood, Stafford.

RESIDENCE, *Leamington*, with out-office, coach-office, stabling, entrance gate and lodge, at Eathorpe. Specification, &c., R. Clarke, architect, Shakspere-Street, Nottingham ; to whom tenders on 12th March.

DESIGNS FOR A JEWS' HOSPITAL, *Mile End, London.*—For proposed new buildings. First premium £100 second £50 ; third £30. Instructions of Rev. O. P. Mendis, Jews' Hospital, Mile End, for 5s. deposit. Designs to April 11.

RAILWAY WORKS, *London, Brighton, and South Coast.*—For 1st section of Shoreham, Henfield, and Mid-Sussex Branch, 10 miles. Specifications, Engineers' office, London-bridge Terminus. Printed copies of quantities, &c., £3. Tenders, 11 o'clock, March 10.

RAILWAY STATION, *East Lancashire.*—At New Cocker Bar and Rytford. Plans, Engineers' office, Bury Station. Tenders, Mr. Myles Fenton, secretary, March 9.

SWITCHES AND CROSSINGS, *Fort Patrick.*—Seventy sets. Drawings, &c., of Messrs. B. and E. Blyth, engineers, Edinburgh, with whom tenders, March 15.

IRON GIRDERS, *Lymington, Biggar, and Broughton Railway.*—Wrought and cast. Drawings, &c., of Messrs. Bruce and Cunningham, engineers, 21 Castle-street, Edinburgh. Tenders with Mr. D. Thomson, secretary, Biggar, March 15.

GAS HOLDER TANK AND GAS HOLDER, *Burton.*—With columns, girders, &c. ; also 300 yards of 9-in. main pipes. Plans at office of Buxton Gas Company. Tenders to chairman, 12th March.

EIGHTY HYDRANTS, *Barnstaple.*—For Water Supply Company. Tenders, with specimens or drawings, to chairman, March 8.

PORTABLE RACE STAND, *Oldham.*—Plans, &c., Mr. G. B. Mussillwhite, New St. Basingstoke, Hants. Tenders to Mr. J. Trodd, clerk to course, Oldham, March 14. Copies of quantities of Mr. Mussillwhite, for 5s.

BRIDGE, *County Wicklow.*—Plans, &c., Grand Jury Office, Wicklow. No date.

BRIDGE, *Birmingham.*—Over river Rea. Plans, &c., at office of borough surveyor, Moon-street. Tenders, 2 o'clock, 12th March.

WORKHOUSE, *Shoreditch.*—Alterations. Plans, Mr. T. H. Jones, the Tower, Dalston, March 12.

LUNATIC ASYLUM, *Chester.*—Additions, with chaplain's house, heating apparatus for drying, stoves, &c. Plans of Mr. T. M. Pearson, architect, the Bars, Chester, March 14.

ORPHAN ASYLUM, *Sunderland.*—Plans, &c., Mr. T. Mooro, architect, Sunderland, March 9.

BATHS AND WASH-HOUSES, *St. Martin's-in-the-Fields.*—Alterations and additions. Particulars of Messrs. Balam and Lee, 10 Buckingham-street, Adelphi. March 15.

BARRACKS WORK.—Bricklayers', masons', carpenters', plumbers', painters', slaters', glaziers', and paper hangers', smiths', and paviors' works of Dorchester and Weymouth Barracks, Portland Castle, Verne Barracks, Portland, from April 1, 1859, to March 31, 1862. Information till March 9, at Royal Engineer office, Hope-street, Weymouth. Tenders, March 14.

INDEPENDENT CHAPEL AND SCHOOLS, *Bridport.*—Plans, Mr. R. Swayne, East-street, Bridport. Information and bills, Messrs. Poulton and Woodman, Reading. March 10.

FREE GRAMMAR SCHOOL, *Stourbridge.*—Plans of Messrs. Freer and Perry, Solicitors, Stourbridge ; to whom tenders, addressed to "Mr. Edward Hickman Freer, Sec." March 19.

POLICE STATION, *Moseley, near Birmingham.*—Plans at Police Station, Moseley. Tenders to Clerk of Peace's Office, Shire Hall, Worcester, till 18th of March.

POLICE STATIONS, *Thrapstone, Northamptonshire.*—Residence for two officers, three cells, &c. Plans, Mr. James Milne, County Surveyor. March 18.

VILLA RESIDENCE, *Folkestone.*—Plans, &c., Mr. J. Messenger, Architect, Folkestone, or 9 Spring-gardens, London. Tenders, March 9.

RESIDENCE, *Leamington.*—At Eathorpe. Plans, &c., Mr. R. Clarke, Architect, Shakspeare-street, Nottingham ; where tenders, March 12.

HOUSES, *Wandsworth.*—Five fourth-rate, York-road, near Railway-station. Drawings, 1 Carlton-cottages, Biggs's-row, Putney ; where tenders to J. Niblett, Jun., March 10.

SEWERAGE, *Gateshead.*—Laying a sewer and building a wall. Specifications, Surveyor to the Local Board, March 10.

SEWERS, *Harrow.*—1,200 feet of Doulton's stoneware 9 in. pipe sewer. Specifications, Mr. W. Smith, surveyor to the Local Board, March 8.

FOOTPATHS, *Birmingham.*—For a year. Specifications, Borough Surveyor's, Moor-st. Tenders, March 12.

CLOSING THE VAULTS OF ST. PANCRAS.—Specification, Mr. John Dent, 34 Great James-st., Bedford-row, and Mr. W. B. Scott, 10 Edward-street, Hampstead-road. Tenders March 7, Messrs. Scadding and Son, 1 Gordon-street, Gordon-square.

TOOLED YORK-STREET FLAGGING.—800 yards of 2½ inch in stones of not less than 4 feet sup., to be delivered at Milverton station, London and North Western Railway, Leamington Messrs. G. Clark and Son, Warwick, March 10.

DESIGNS FOR NEW ROMAN CATHOLIC CHURCH, *Castle Connell.*—Premium £20. Plans to Rev. P. Hennessy, P. P., to March 20.

DESIGNS FOR POLICE STATION, *Birmingham.*—Particulars at office of the Town Clerk, Temple-st., 14th March.

DESIGN FOR CLOCK TOWER.—For Burnley Improvement Commissioners. First premium 10 and second 15 guineas. Further information of Mr. W. H. Colbran, surveyor to the Commissioners, March 28.

DESIGNS FOR OBELISK.—As the Barnston Memorial, near village of Farndon. First premium 10 and the second 5 guineas. Height 60 feet, cost £100. Designs to John Churton, Hon. Sec., Auction Mart, Chester.

AS FOREMAN OVER MOULDERS.—A. 57, *Manchester Guardian.*

AS SURVEYOR and INSPECTOR OF NUISANCES, *Bideford.*—Salary £80. Applications to Town Clerk, March 12.

The same for *Dukinfield.*—Salary £70, with house, coal, and gas. Application March 7, to Mr. John Brooks, Law Clerk to the Board.

AS FOREMAN PATTERN MAKER.—Good knowledge of marine and stationary engines and general machinery. A. 69, *Manchester Guardian.*

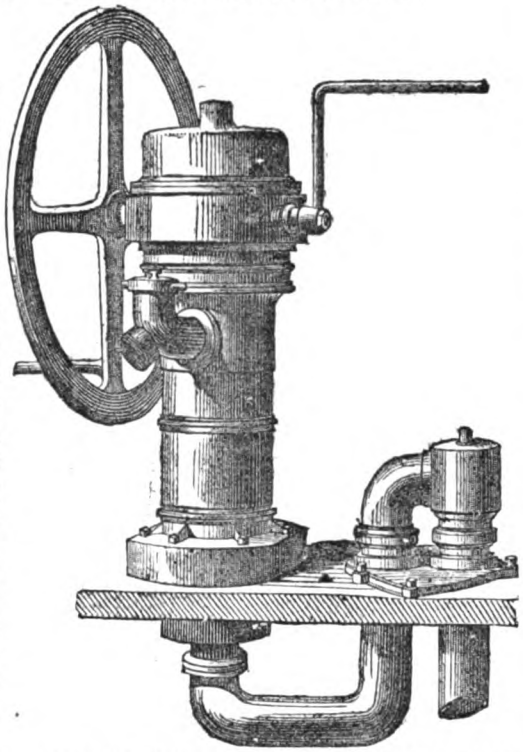
Digitized by Google

Under the Patronage of the Board of Admiralty.

SHIPS' PUMPS OF HER MAJESTY'S NAVY.

JOSIAH STONE,

Sole Manufacturer of DOWNTON'S well-known and much approved SHIPS' PUMPS, which have been used in preference to all others on board the vessels of Her Majesty's Navy, for upwards of thirty years, and have given the greatest satisfaction, effectually answering all the purposes required of any Ships' Pumps, and capable of throwing most powerful jets of water in case of fire.



These Pumps have also been most extensively used on board merchant vessels, both at home and abroad, and have been supplied to the Royal Navies of France, Prussia, Holland, Russia, Spain, and Turkey. The Pumps are portable, as they may be easily removed from the ship and put to work in a boat alongside in a few minutes. Each pump is fitted with a large foot valve plate (which may be placed in any part of the vessel most convenient), and from which communication is made to any number of distinct compartments in the vessel. In case of any of these pipes fouling, the water, by an almost momentary attachment, may be forced from the Pump downwards, so as to clear all obstructions, preventing any possibility of stoppage. The valves are of the simplest description, and being faced with ordinary leather discs, the latter may be renewed in a few minutes by the most inexperienced hands. By the peculiar construction of these Pumps, a most perfect and uninterrupted flow of water may be maintained; so uniform as to be undistinguishable from that proceeding from a cistern. The Pumps are made of several sizes, those of 7, 9, and 12 inches bore being most generally used. They may, however, be ordered of any dimensions required, and may be fitted either with one or two fly wheels. A standard, &c., is also supplied with these Pumps, to enable them, when necessary, to be used as ordinary hand-lever pumps.

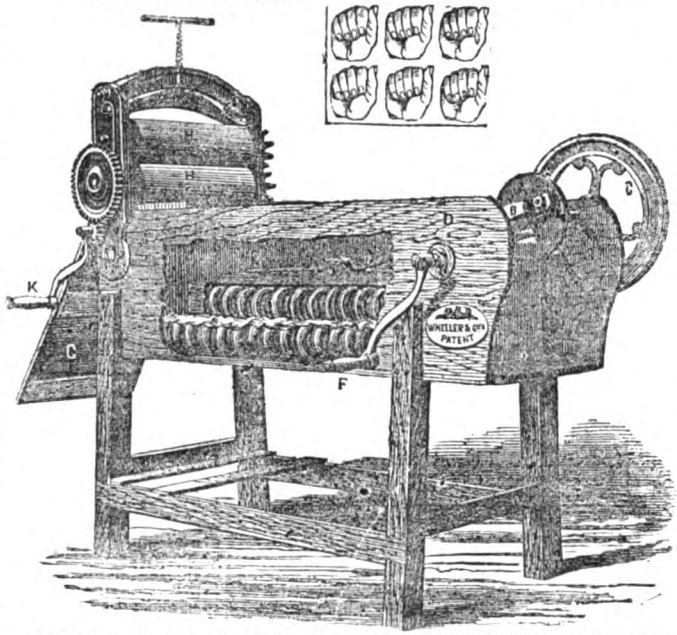
JOSIAH STONE, Engineer, Manufacturer of all descriptions of PUMPS and FIRE ENGINES for Land and Ships' Use; Brass and Iron Founder and Finisher, Nail and Rivet Maker, &c.

CONTRACTORS FOR FIRE-ENGINES, ETC., TO THE WAR DEPARTMENT,

RAILWAY STATION, DEPTFORD, AND 12 GARLICK HILL, CITY, E.C. (97)

T. WHEELER AND CO.'S

"OXONIAN KNUCKLE WASHING MACHINE."



The Improvements in these New Inventions are the non-exposure of the user's hands to the dangerous parts of the Machine, and the rapidity with which the work is done. These Machines have neither bands or wheels passing on the outside, wherein lies the liability to accident. The rubbers are the truest representation of the knuckles or hand washing yet brought out; the compensating floating rubbers work at right angles, backward and forward, in the same manner as does the hands. These Machines can be supplied with rubbers that represent a person's hand in the action of rubbing; the knuckles, finger nails, and palm of the hand being truly modelled. They are capable of Washing Clothes of every description whatsoever, the largest bedding to the most delicate piece of muslin can be washed without breaking a single thread; in fact, such is the delicacy of the action of these Machines, that the paper you are now reading can be passed between the rubbers without sustaining any injury, at the same time being thoroughly effective in cleansing. The Patentees confidently recommend these Machines to the notice of Laundresses, Heads of Families, Hotels, Emigrants, &c. So simple is the action of this Machine, that a boy or girl of 10 or 12 years of age can work it; the only skill required is to soak the clothes one hour before placing them in the Machine, placing a portion of the clothes at the handle end of the Machine; laying on the rubbers a part of them; turn the handle, and the clothes will pass through between the rubbers to the opposite end, effecting a saving of at least 50 per cent.

Prices: Washing Machines, £1 6s., £2 6s., £3 6s., £4 10s., £5 15s.; Washing, Wringing, and Mangling, £8 £10 15s., £14 14s.—Full Instructions sent with every Machine. Testimonials or References sent on application.

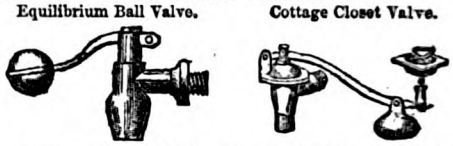
TO BRASS-FOUNDERS, ENGINEERS, &c.

THE PATENT PLUMBAGO CRUCIBLE COMPANY having completed the enlargement of their premises, beg to call the attention of all users and shippers of Melting Pots to the great superiority of the PATENT CRUCIBLES, which have been used during the last three years by some of the largest melters in England and abroad. In addition to their capabilities of melting an average of from thirty-five to forty pourings; they are unaffected by change of temperature, never crack, but can be used till worn out, requiring only one annealing for several days' work, and become heated much more rapidly than ordinary pots, effecting thereby a saving of more than fifty ber cent. in time, labour, fuel, and waste. The Patent Plumbago Crucible Company also manufacture and import clay crucibles, muffles, portable furnaces, sublimate pans and covers, glass-pots, all descriptions of fire- standing goods, and every requisite for the assayer and dentists. For Lists, Testimonials, &c., apply to Battersea Works, London, &c. (43)

HIGH-PRESSURE VALVE-COCKS,

LAMBERT'S PATENT.

Equilibrium Ball Valve. Cottage Closet Valve.



The Equilibrium Ball-Valve is simple and certain in its action, and is cheaper than the common cocks now in use.

The Cottage Valves are suitable for application to any kind of basin; and, as they shut against the pressure, no concussion in the pipes can possibly occur.

These cocks have been extensively and most successfully used in many towns, under continuous high pressure, varying from 100 to 350 feet; their efficiency and durability is, by experience, established.

THOMAS LAMBERT and SON,

Brass Founders, Short-street, New-cut, Lambeth. (80)

PUMPING MACHINERY.

GWYNNE AND Co., Engineers, London, manufacture and supply the following Machinery, of the most approved construction and with all the latest improvements:—Portable and Fixed Steam-Engines and Boilers of every description; Waterwheels, Windmills, Horse and Hand-power Machines; Pumping Machinery for the Supply of Towns, Cities, and Districts, and for the Irrigation of Coffee, Cotton, Indigo, Sugar-cane, and Rice Estates, for pumping out Coffer-dams, Canals, Dry Docks, Reservoirs, &c. They also manufacture and supply the Pumping and other Machinery for Paper, Pulp, and Fulling Mills, Breweries, Distilleries, Tanneries, Starch Works, Bleaching, Dyeing, and Calico Printing Works, Chemical Works, Silk, Cotton, and Flax Mills, and Manufactories in general. All Letters not paid will be refused. Illustrated Price Lists forwarded on receipt of Six Postage Stamps.—GWYNNE AND Co., Hydraulic and Mechanical Engineers, Essex-wharf, Strand, London.

For Exportation.—The above can be obtained through British Merchants, Shippers, and Colonial Agents. (24)

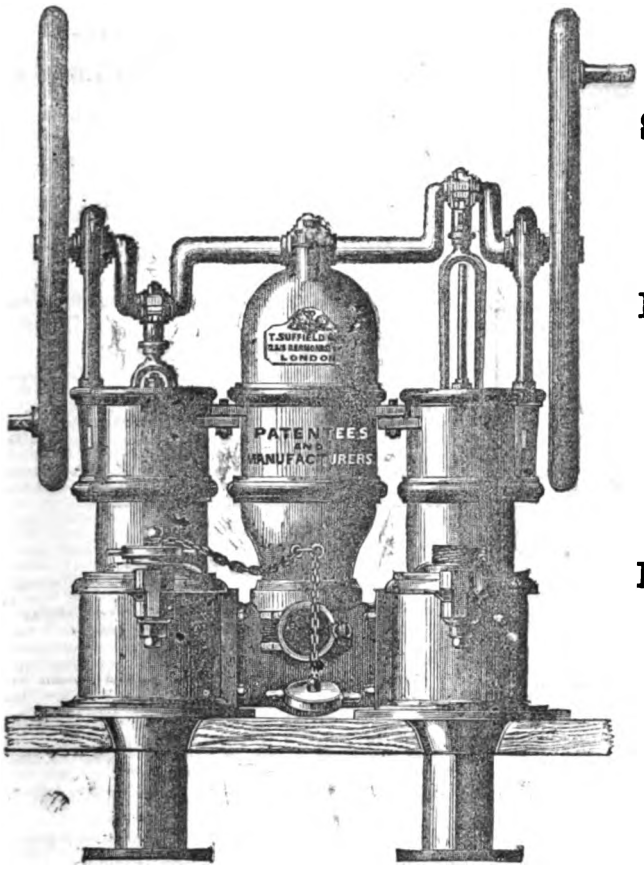
to the Simple and Efficient Arrangements of their

PATENT PUMPS.



Ships' Pumps

AND

Fire Engines,

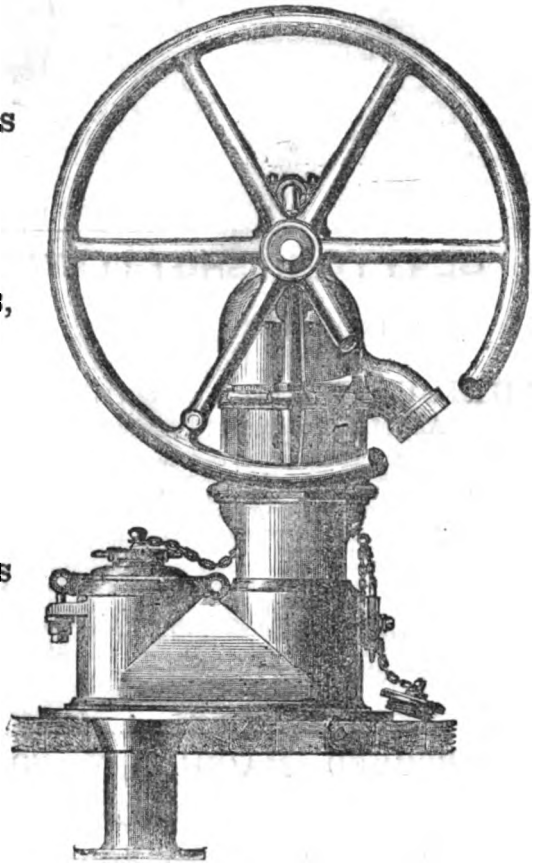
Fixed and Portable.

WITH

Patent Valves

AND OTHER

Improvements.



These Pumps are free from that liability to choke which is common to other Pumps, and their Working Parts are not susceptible of derangement either from wear or from being long out of use. They pass entirely through them, with ease, any substance that may enter the Suction Pipes. The Novelties in these Pumps are their adaptation to the varied duties of Ships' Pumps; the facilities they afford for Cleansing the Suction Pipes, and for Sounding or Examining the Valves; the readiness with which they may be used for Ventilating the Bilge, or for acting as a Syphon either for Watering the Ship, or for extinguishing Accidental Fires on board; the rapidity with which they can be converted into Fire Pumps, or be applied to the Washing of Decks; and their capability of Pumping from Several Compartments.

T. SUFFIELD AND CO.

Also respectfully solicit the attention of STEAM SHIP BUILDERS and OWNERS to their Large and Varied STOCK of

ASSORTED STORES FOR MARINE PURPOSES.

They keep a Large Stock of Goods, of their own Manufacture and from the Best Makers, constantly on view; so that by a visit to their Works or Depôt, much valuable time may be saved by Managers, Engineers, and other Gentlemen who may require such Stores, together with a further saving in the cost of such Articles.

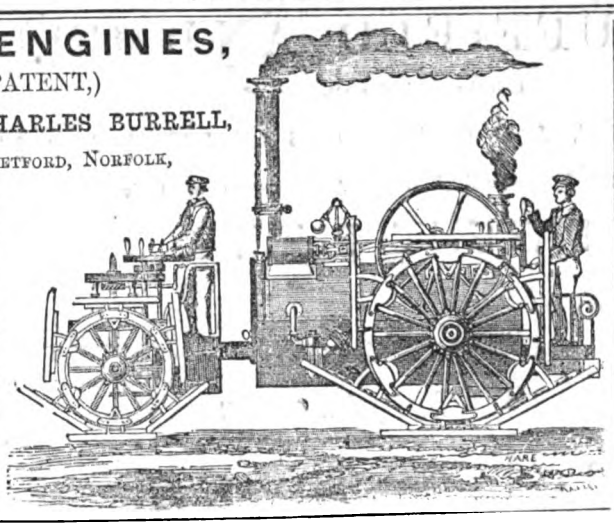
TRACTION ENGINES,

(BOYDELL'S PATENT,)

MANUFACTURED BY CHARLES BURRELL,

ST. NICHOLAS WORKS, THETFORD, NORFOLK,



And ordered for India, Australia, and South America, may now be seen, complete and in course of construction at the above works. BOYDELL'S TRACTION ENGINES AND ENDLESS RAILWAY will draw heavier loads over good roads than any other traction engine, and on soft and bad roads will draw heavy loads where no other traction engine can move itself. All objection to the wear and tear of these Engines is entirely removed by the use of Charles Burrell's improved patent Wrought Iron Wheels, fitted with Rails and Tyre, as well as all the wearing parts, of Steel.

Apply also to Mr. Hemming, 47 Mark Lane, E.C.

CLAYTON, SHUTTLEWORTH, AND CO.,

OF LINCOLN,

78 LOMBARD STREET, LONDON, E.C.,

AND 36 DALE STREET, LIVERPOOL,

AGRICULTURAL AND GENERAL ENGINEERS,

And Manufacturers of Portable and Fixed Steam Engines.

Combined Threshing Machines, which dress the corn ready for market at one operation. Grinding Mills, Saw Benches, Pumps for Irrigation and Mining purposes, with all necessary gearing for being driven by steam power. Full particulars and estimates given on application to the above address.

C. S. and Co.'s PORTABLE STEAM ENGINES are adapted for every purpose to which steam-power can be applied. When intended for winding, they are fitted with reversible link motion and winding gear. They are easy of removal, as may be seen by the engraving, and can be set to work immediately on arrival.

C. S. and Co. are now doing an extensive foreign and colonial business, and are prepared to send off engines and machinery of the before-mentioned kinds in a few days from the date of order. They would also call attention to the important *reduction in prices* made for the new year.

For Exportation.—The above can be obtained through British Merchants, Shippers, and Colonial Agents. (23)

IMPROVED MACHINERY FOR AGRICULTURISTS.

RICHARD GARRETT & SONS,

LEISTON WORKS, SAXMUNDHAM, SUFFOLK,

(ESTABLISHED A.D. 1778),

EARNESTLY solicit the continued support of their numerous Friends, Agriculturists, Shippers, and others; the additions made to their Works during the present year, in the erection of new sets of Workshops, fitted with the best mechanical appliances for producing Machinery of the most improved construction, expeditiously and economically, justifies their soliciting increased support, while their leading reputation as Inventors and Manufacturers of FIRST CLASS Agricultural Machinery, is a sufficient guarantee that every Machine supplied from Leiston Works will prove to the entire satisfaction of the purchaser.

R. G. & S. are now manufacturing the following Machines and Implements, which they guarantee to be thoroughly efficient in every respect:—

PORTABLE AND FIXED STEAM ENGINES. } From 4 to 40 Horse Power, suited for every kind of work
SELF-PROPELLING AND TRACTION ENGINES. } to which Steam Power is applied.

STONE GRINDING MILLS.
MORTAR AND PUG MILLS.
MILLWRIGHTS' WORK of all kinds.
SAWING MACHINERY, from 4 to 20 Horse Power.
BRICK AND TILE MACHINES.

IMPROVED SETS OF FARM MACHINERY, for Large Occupations.
PORTABLE AND FIXED MACHINERY, for Thrashing and Dressing Corn.
THE PRIZE BOLTING AND OPEN-DRUM HORSE-POWER THRASHING MACHINES.
CORN DRESSING MACHINES, for Hand, Horse, Water, and Steam Power.
BARLEY AVELLING MACHINES.
CHAFF CUTTERS, for Hand, Horse, Water, and Steam Power.
PATENT TURNIP CUTTING AND PULPING MACHINES.

THE PRIZE CORN AND SEED DRILLS.
PRIZE CORN AND SEED DRILLS WITH MANURE APPARATUS.
PRIZE SEED AND MANURE DRILLS.
LIQUID, SEED, AND MANURE DROP DRILLS.
CHAMBER'S PATENT BROADCAST MANURE DISTRIBUTOR.
GARRETT'S PATENT HORSE HOE for all Crops.
PATENT REVOLVING HOES for Root Crops.
IMPROVED PLOUGHS AND REAPING MACHINES.
&c. &c. &c.

Of which full detailed particulars will be found in R. G. & SONS' ILLUSTRATED CATALOGUE, sent postage free to any address, in English, French, or German; and any of the above Machines will be shown in operation at R. G. & Sons' Farm, near the Works, on their receiving a few days' notice.

A Copy of R. G. & SONS' new COLONIAL LIST will be forwarded free to any of the Colonies, and Shippers will be supplied with these lists, with their names and addresses printed on, free of charge, by making application for the same.

ADDRESS—R. GARRETT & SONS, LEISTON WORKS, SAXMUNDHAM, SUFFOLK. (161)

WATER POISONED BY LEADEN PIPES.

"The above engraving represents accurately a section of a leaden pipe, which was employed for a short time in conveying water from a well on the grounds of Mr. Dick, of Bonchurch, Isle of Wight. The water has cut these deep pits almost through the pipe, and not only upon the portion which we have illustrated, but has formed similar chasms throughout the entire length."—*Expositor.*

Poisoned Water Preventable.

BY THE USE OF GUTTA PERCHA TUBING.

The Gutta Percha Company have been favoured with the following letter,

From Dr. MURRAY, Hull.

"It is impossible to conceive of anything more injurious, or destructive to the health of the community than the use of *leaden pipes* for the conveyance of water. The poisonous salts of lead thereby communicated are most insidious and subtle. I hail with gratitude the substitution of Gutta Percha Tubing. I have had the leaden pipe of my own house removed, and its place supplied with one of Gutta Percha. Nothing can be better. I have also recommended it to others, who have adopted the expedient.

Resistance for Frost.

The Gutta Percha Company have been favoured with the following Letters in reference to the non-conducting properties of Gutta Percha Tubing, in the resistance of Frost.

From J. ARMSTRONG, Esq., M.D., Gravesend.

"My private house, which was supplied with your Gutta Percha Tubing some five or six years ago, has never required the slightest attention; and previously, there was no winter passed that we were not deluged in consequence of the bursting of the leaden pipes."

From HENRY BROWN and SONS, Western Works, 108 Rockingham-street, Sheffield.

"We have now a positive proof of the frost-resisting properties of the Gutta Percha Piping. On our premises we have a leaden Pipe and a Gutta Percha one lying side by side. The leaden one has been completely frozen up at least ten days, and the Gutta Percha one is still unaffected.

SOCIETY OF ARTS.—The Eleventh Annual Exhibition of Inventions will open on the 25th day of April, 1859. The days fixed for receiving articles intended for exhibition are Thursday the 7th, Friday the 8th, and Saturday the 9th April. No charge is made for space, and the Exhibition is Free.

Intending exhibitors should communicate at once with the Secretary. By order,

P. LE NEVE FOSTER,
Society House, John-street, Secretary.
Adelphi, 1st March, 1859. (171)

BRICKS.

TO BE LET, with immediate possession, in consequence of the death of the proprietor, J. M. Paine, the DIPPENHALL SILICA FACTORY, erected for the purpose of making improved Fire Bricks, Building Bricks, Paving Tiles, &c., &c., from the Soluble Silica Rock.

Apply to view the Buildings and Bricks to G. H. Ogston, Esq., Resident Manager, Dippenhall, Farnham, Surrey; and for terms, to Messrs. Nicholls and Potter, Solicitors, Farnham. (125)

GLADSTONE & Co., CONTRACTORS and ENGINEERS.
2 John-Street, Minories, London, E.C.,
Are prepared to ESTIMATE FOR and CONSTRUCT BRIDGES, PIERS, JETTIES, &c., in Iron, Wood, or Stone. Also to supply Cranes, Girders, Turntables, and Railway Work and Plant generally. (56)

THORLEY'S FOOD FOR CATTLE.—Every person having an interest in domestic or farm animals should obtain a supply of this celebrated and economical food, which will prove invaluable during the approaching season. For keeping horses in good condition, it is unequalled. Pigs fatten with surprising rapidity upon it, and their flesh increases in flavour and value. Cowkeepers will find great advantage in the increased quantity and improved quality of the milk during its use. All animals are benefited by it. A pamphlet on this interesting subject, accompanied by Testimonials from the principal Nobility, Gentry, and Agriculturists, forwarded on application. In Casks containing 448 Feeds (Measures enclosed). Price 50s., carriage paid to any Railway Station in the United Kingdom. Post Office Orders payable to JOSEPH THORLEY, 77 Newgate Street, London.

N.B.—The public are cautioned against being imposed upon by worthless imitations. (132)

HART & SON, MALLEABLE IRON-FOUNDERS, 4 Vine-street, York-road, Lambeth. Orders for Malleable Iron Castings executed within a week. (77)

TO BRASS FOUNDERS.

TO BE SOLD, the Patent-right of a New and Highly-approved EQUILIBRIUM WATER COCK or VALVE, suitable for Steam Boiler Feed Pipes, or any cases where the valve is required to be opened against pressure,

Address H., MECHANICS' MAGAZINE Office, 166 Fleet-st., where a Drawing may be seen. (151)

STEAM ENGINES.

FOR SALE, a superior HIGH PRESSURE HORIZONTAL STEAM ENGINE of 6-horse power, 8-inch cylinder, and 1-foot 6-inch stroke. One of 8-horse power, 10-inch cylinder, and 1-foot 6-inch stroke. One of 10-horse power, 12-inch cylinder, and 2-feet stroke. Two of 14-horse power, 14-inch cylinders, and 2-feet stroke; and one of 30-horse power, 20-inch cylinder, and 3-feet stroke.

Apply to Messrs. PAGE and CAMERON, 64 Old Broad Street, E. C., London. (124)

ENGINEERING AND MECHANICAL DRAWING CLASSES.—Instruction given in Engineering and Mechanical Drawing, comprising the preparation of plans, elevations, and sections of marine and locomotive engines, with the detail and working drawings; also the method of delineating screws, bevel wheels, &c.; orthographical projection, and tinting, shading, and colouring taught.—For prospectuses of the Day and Evening Classes apply to Mr. T. J. HILL, at the offices, 15, Old-street, City-road. (73)

TO MARINE ENGINEERS, OR SHIP-BUILDERS.

THE PROPRIETOR of a VALUABLE PATENT for Double-expansive Marine Engines (by which great economy of space and fuel is obtained) is desirous of entering into arrangements with a respectable firm for the construction of the same. An adequate portion of the patent-right would be assigned by the advertiser to any firm taking the matter up; and he would render all assistance in his power, either in London or elsewhere, amongst ship-owners (to many of whom he is well known), in obtaining contracts, &c. Unexceptionable references given. Address C. E., MECHANICS' MAGAZINE Office, 166, Fleet-street. (75)

ENGINEERING BUSINESS FOR SALE.

OWING to the continued ill health of the Proprietor, the first-class business of an Engineer and Crane and Block Maker is offered for sale. It has been established in the Metropolis for nearly 30 years, and has enjoyed extensive patronage amongst Brewers, Manufacturers, Warehousemen, and others, in and about London; the business done amounting to nearly £8,000 per annum. About £3,200 would be required, (part of which, however, may remain for any reasonable time on good security,) which is the bare value of the tools, patterns, and stock in trade. The premises, including good dwelling-house, very conveniently situated, and capable of accommodating from 60 to 70 hands, are held upon a long lease, at an extraordinary low rental, not exceeding £100 per annum, taxes included. Many of the tools are nearly new, and of the best construction. The present proprietor, who relinquishes the business solely on account of ill health, would give every assistance in his power to those succeeding him; and as his foreman, who has been with him for nearly ten years, is thoroughly acquainted with the practical parts of the business, any gentleman desirous of commencing as a manufacturing engineer would find the present a very favourable opportunity. As all accounts have been, for many years past, collected quarterly, a very small amount, say £800, would suffice as working capital. Full particulars may be obtained by application to E. E. ALLEN, Esq., MECHANICS' MAGAZINE Office, 166 Fleet Street, E.C. (130)

INDIA-RUBBER VALVES FOR STEAM ENGINES, PUMP PACKING, &c. — Explanatory Drawings and Information as to the best modes of fitting and arranging the above, and all other Mechanical Applications of VULCANISED INDIA-RUBBER, are furnished post-free by

CHARLES MACINTOSH & Co., Patentees,
Cambridge-st., Manchester, and 3 Cannon-st. West, London.
MANUFACTORY and DEPÔT, Cambridge-st., Manchester.
GENERAL WAREHOUSE, 3 Cannon-street West, London, E.C.—C. M. and Co.'s only Establishments. (139)

TO COMMERCIAL TRAVELLERS.

WANTED, a Gentleman well-acquainted with Ironmongers, Upholsterers, Coopers, &c., to Travel on Commission.

Address, A. Z., MECHANICS' MAGAZINE Office, 166 Fleet-street. (164)

AN ENGAGEMENT IS OPEN for a Mechanical Draughtsman and General Assistant. One who speaks and writes French is indispensable, and of active business habits, with practical knowledge of Engineering and Machinery preferred.

Apply by letter *only*, stating Age, Salary, and References, to H. CLAYTON, Atlas Works, Upper Park-place, Dorset-square, London. (176)

TO ENGINEERS, INVENTORS, AND OTHERS.

A PRACTICAL ENGINEER of long standing prepares Original Drawings, Copies, and Tracings. Advice and Assistance given to Inventors in working out their Plans. Pupils taught privately. Terms moderate.

Apply to J. J., 171 Strand. (138)

TO ENGINEERS, ARCHITECTS, PATENT AGENTS, &c.

PHOTOGRAPHS OF THE HIGHEST CLASS and of any size, taken and reproduced at a most moderate rate of charge. Reproductions of faultless accuracy, of Machinery, Models, Drawings, &c. Orders attended to in town and country. Estimates forwarded.

SPENCER, READ, & Co., 4 Agar-street, Strand, W.C. (90)

A VALUABLE PATENT to be DISPOSED OF.—The Patentee will either dispose of the Patent or grant Licences to any party wishing to manufacture, or would join a person with capital to carry out the Patent.

Address, A. Z., MECHANICS' MAGAZINE Office, 166 Fleet-street. (163)

ENORMOUS REDUCTION IN THE COST OF STEAM POWER.

TO RAILWAY COMPANIES, STEAM SHIP PROPRIETORS, AND MANUFACTURERS.—A saving of Fuel equal to one-third of the entire consumption is effected by the introduction of "DUNCAN'S PATENT SPIRAL HEAT DIFFUSERS," which arrest the heat in its passage through the flues or tubes, and convert into impelling power the large measure that without these appliances would (even in the very best boilers) escape along with the smoke. They can be fitted in an hour or two at a small cost, and without any alteration in the existing arrangements of boilers now in use. These results are prepared to be guaranteed, and a part of the value of fuel saved by the use of the Apparatus will be accepted for royalty.

Hitherto, steam navigation to distant parts of the world has proved a commercial failure. The remedy is provided, and the vast numbers of large and splendid vessels can soon be made valuable paying property.

Further information may be had on application to GWYNNE and CO., Engineers, Essex-street Wharves, Strand, W.C., London. (178)

CAUTION.

TO ARCHITECTS AND BUILDERS.—In consequence of numerous complaints, the Patentee begs to inform the above, that all genuine SMITH'S PATENT DOOR SPRINGS, for Swing Doors, are stamped with Name and Address, thus—SMITH, Patentee, 69 Princes Street, Leicester Square, London; and that Springs thus marked are warranted. SMITH'S PATENT WEATHER-TIGHT CASEMENT FASTENING AND SILL-BARS are admitted by all to be the most perfect invention for the purpose. Diagrams and List of Prices on application. (143)

STEAM ENGINES FOR SALE.

PORTABLE STEAM ENGINES, from 6 to 12 horse power,
STATIONARY STEAM ENGINES, from 4 to 50 horse power,
TUBULAR BOILERS, from 4 to 50 horse power,
CORNISH BOILERS, from 4 to 50 horse power,

Are in hand, and can be despatched on eight days' notice. Prices moderate. Workmanship and Material of the best description.

Apply to R. THORNTON & Co., St. Leonard's Iron Works, Edinburgh. (60)

VENTILATION WITHOUT FLUES.

KUKLA'S PATENT STOVES,

At 18s., 25s., and 50s.

KUKLA'S newly-invented Deflagrator—the first and only perfect GAS STOVE. Guaranteed to burn without flue—without dust, smell, or smoke, producing a great and pure heat with the least expenditure of Gas.—*Vide Society of Arts' Journal.*

Patronised by the English and French Government.

Scientific in Principle,
Simple in Construction,
Healthy and efficient in use.

The Deflagrator Stove is cheap, portable, and suited for every situation; and from the principle on which it is constructed (viz., expanding to a sixfold volume the gas used) is capable of warming any given space more quickly and more thoroughly than any other means: while its addition forms a sure remedy for any ill-warmed or ill-ventilated apartments.

The 25s. Deflagrator warms a room of 2,000 cubic feet at a cost of 3d. per day.

The 50s. Deflagrator warms 5 to 6,000 cubic feet at a cost of 6d. per day (twelve hours). Also, the Greenhouse Stove at 18s.

Patentee and sole Manufacturer, F. X. KUKLA, 194 Pentonville-road, London.

Country orders promptly attended to. Carriage free to any Railway in London.

Post-office Orders should be made payable to FRANCIS XAVIER KUKLA, General Office.

N.B.—Every Stove separately tested before sent out.

The New Gas Cooking Stove for 10 persons, price £3. (103)

PIERCE'S

UNRIVALLED

PYRO-PNEUMATIC FIRE-LUMP WARMING AND VENTILATING STOVE GRATES,

WITH the cheerful, open fire, producing healthful warmth, with continuous Self-acting Ventilation, for Churches, Schools, Public Buildings, Banking Houses, &c. These Grates are manufactured solely by PIERCE, the Inventor, for which he received the Prize Medals of London in 1851, and of Paris in 1855.

PRICE, from £7 10s.

ILLUSTRATED CATALOGUE, with Prices and Estimates for Work, furnished on application to the Inventor and Sole Manufacturer.

Also his

IMPROVED COTTAGER'S GRATE,

For Warming Two Rooms with only One Fire. Prices, 30s. and 35s.

PIERCE, No. 5 JERMYN STREET, REGENT STREET. (111)

TO STEAM SHIP OWNERS, ENGINEERS, AND OTHERS.

How's Patent Steam Engine Counters, can be read at sight.

These Counters register the number of revolutions made by an engine or other mechanism. They may be used for ascertaining the duty of Pumping Engines and Water-wheels; the revolutions on board a steam-vessel; to calculate the slip of the propeller; and in a locomotive to test the slip of the wheels.

How's Patent Salinometer, for Steam Boilers using Salt Water.

By these, the density of the water in the Boiler is at all times accurately shown, and a saving of boiler and fuel is effected. They are adopted by the Admiralty, the Honorable Trinity Corporation, and others. Copies of Testimonials from Messrs. Penn, Messrs. Maudslay, and others, will be forwarded on application.

How's Engine-Room Telegraph, for communicating between Captain and Engineer. Society of Arts Prize Medal, 1855.

is a Mechanical Telegraph, and by its peculiar construction, error or misunderstanding is rendered impossible. It is now extensively adopted, and gives great satisfaction.

How's Patent Fresh Water Apparatus for Ships' Use.

This apparatus is designed for the distillation of Fresh from Salt Water; and on long voyages, and where the supply of water is scanty, it will be found invaluable. Testimonials may be seen.

Patent Steam Pump and Fire-Engine for Ships' Use.

This Steam-pump occupies but a small space; works perfectly noiselessly, and throws an immense volume of water. An Illustrated Circular of Fresh Water Apparatus and Steam-pump combined, free on application.

How's Patent Machine for Cutting Bolts, Rods, Spindles, Wire, &c.

Simple in construction, inexpensive, occupies but little space, and will not easily get out of order.

A Pamphlet Illustrative of the above, sent free by post, on application to

A. P. HOW, ENGINEER,

81 MARK LANE, LONDON.

EVERY DESCRIPTION OF ENGINEERS' TOOLS, ENGINE ROOM STORES, &c., &c., SUPPLIED. (89)

ARTESIAN WELLS, BORING TOOLS, PUMPS, &c. Engineers, Architects, Surveyors, Builders or others requiring a good supply of Water may have any quantity procured by W. SPELLER, 14 York-street, Blackfriars'-road, London, where may be had any quantity of Tools for Sinking or Boring, from 2 to 20 inches diameter, and from 100 to 2,000 feet depth; also Men and Tools to bore for Railroads, Minerals, &c., in any part of the world. Boring Tools and suitable Pipes for exportation, with full instructions for their use.

Builders, Contractors, Brickmakers, Barge and Ship Builders, and others, can be supplied with Wrought or Cast Iron Pumps, Double or Single, for excavation of Deep Wells, from 3 to 14 inches in the bore, and from 6 to 130 feet in length, to work by Hand or Steam Power.

Hot-water Apparatus for Conservatories, &c., on the most economical and improved principles.

Also Manufactory for Captain John Grant's much improved Cooking Apparatus. (44)

AT SUFFELL'S, 132 Long-acre, London, W.C., every Instrument suitable for Engineers, Contractors, Surveyors, Architects, Draftsmen, &c., to be had second hand at very reduced prices, by the most esteemed makers, consisting of Theodolites, Levels, Circumferenters, Sextants, Compasses, Protractors, Station Pointers, Adygraphs, Pentagraphs, Telescopes, Microscopes, Cases of Drawing Instruments, &c.; Rules, Scales, Chains, Levelling Staves, and Measures of all nations. Every Instrument warranted. (160)

CHUBB'S LOCKS, FIREPROOF SAFES, CASH AND DEED BOXES.

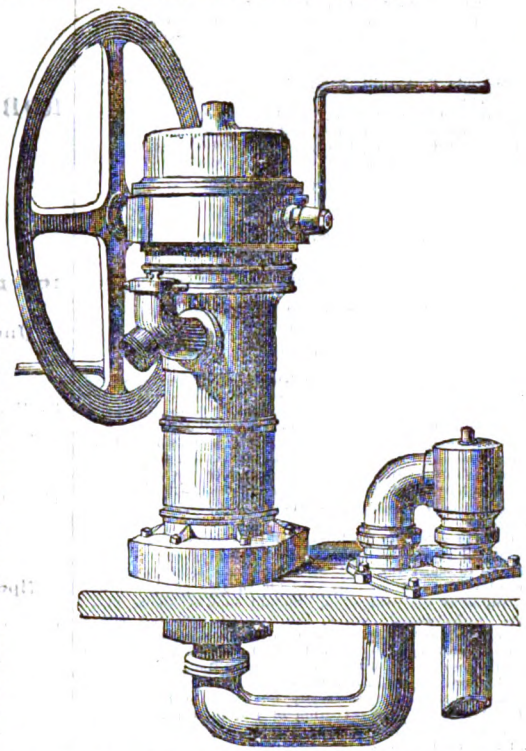
Under the Patronage of the Board of Admiralty.

SHIPS' PUMPS OF HER MAJESTY'S NAVY.

JOSIAH STONE,

Sole Manufacturer of DOWNTON'S well-known and much approved SHIPS' PUMPS, which have been used in preference to all others on board the vessels of Her Majesty's Navy, for upwards of thirty years, and have given the greatest satisfaction, effectually answering all the purposes required of any Ships' Pumps, and capable of throwing most powerful jets of water in case of fire.



These Pumps have also been most extensively used on board merchant vessels, both at home and abroad, and have been supplied to the Royal Navies of France, Prussia, Holland, Russia, Spain, and Turkey. The Pumps are portable, as they may be easily removed from the ship and put to work in a boat alongside in a few minutes. Each pump is fitted with a large foot valve plate (which may be placed in any part of the vessel most convenient), and from which communication is made to any number of distinct compartments in the vessel. In case of any of these pipes fouling, the water, by an almost momentary attachment, may be forced from the Pump downwards, so as to clear all obstructions, preventing any possibility of stoppage. The valves are of the simplest description, and being faced with ordinary leather discs, the latter may be renewed in a few minutes by the most inexperienced hands. By the peculiar construction of these Pumps, a most perfect and uninterrupted flow of water may be maintained; so uniform as to be undistinguishable from that proceeding from a cistern. The Pumps are made of several sizes, those of 7, 9, and 12 inches bore being most generally used. They may, however, be ordered of any dimensions required, and may be fitted either with one or two fly wheels. A standard, &c., is also supplied with these Pumps, to enable them, when necessary, to be used as ordinary hand-lever pumps.

JOSIAH STONE, Engineer, Manufacturer of all descriptions of PUMPS and FIRE ENGINES for Land and Ships' Use; Brass and Iron Founder and Finisher, Nail and Rivet Maker, &c.

THE PATENT CARVING WORKS.—(JORDAN'S PATENT.)—A considerable reduction in the cost of Wood Carving is effected by the aid of the Patented Machinery, as by it the work is roughed out with great accuracy and expedition (the cutters making 7,000 revolutions per minute), while the finishing of the more minute parts is carried out by hand labour, so that the result shows precisely the same amount of artistic excellence as if it had been executed entirely by hand.

The trade supplied with Carving in the rough, or finished.

COX & SON, Belvedere-road, Lambeth. (119)

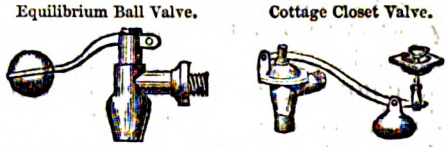
TO BRASS-FOUNDERS, ENGINEERS, &c.

THE PATENT PLUMBAGO CRUCIBLE COMPANY having completed the enlargement of their premises, beg to call the attention of all users and shippers of Melting Pots to the great superiority of the PATENT CRUCIBLES, which have been used during the last three years by some of the largest melters in England and abroad. In addition to their capabilities of melting an average of from thirty-five to forty pourings; they are unaffected by change of temperature, never crack, but can be used till worn out, requiring only one annealing for several days' work, and become heated much more rapidly than ordinary pots, effecting thereby a saving of more than fifty per cent. in time, labour, fuel, and waste. The Patent Plumbago Crucible Company also manufacture and import clay crucibles, muffles, portable furnaces, sublimate pans and covers, glass-pots, all descriptions of fire- standing goods, and every requisite for the assayer and dentists. For Lists, Testimonials, &c., apply to Battersea Works, London, &c. (43)

HIGH-PRESSURE VALVE-COCKS,
LAMBERT'S PATENT.

Equilibrium Ball Valve. Cottage Closet Valve.



The Equilibrium Ball-Valve is simple and certain in its action, and is cheaper than the common cocks now in use.

The Cottage Valves are suitable for application to any kind of basin; and, as they shut against the pressure, no concussion in the pipes can possibly occur.

These cocks have been extensively and most successfully used in many towns, under continuous high pressure, varying from 100 to 350 feet; their efficiency and durability is, by experience, established.

THOMAS LAMBERT and SON,

Brass Founders, Short-street, New-cut, Lambeth. (80)

PUMPING MACHINERY.

GWYNNE AND Co., Engineers, London, manufacture and supply the following Machinery, of the most approved construction and with all the latest improvements:—Portable and Fixed Steam-Engines and Boilers of every description; Waterwheels, Windmills, Horse and Hand-power Machines; Pumping Machinery for the Supply of Towns, Cities, and Districts, and for the Irrigation of Coffee, Cotton, Indigo, Sugar-cane, and Rice Estates, for pumping out Coffer-dams, Canals, Dry Docks, Reservoirs, &c. They also manufacture and supply the Pumping and other Machinery for Paper, Pulp, and Fulling Mills, Breweries, Distilleries, Tanneries, Starch Works, Bleaching, Dyeing, and Calico Printing Works, Chemical Works, Silk, Cotton, and Flax Mills, and Manufactories in general. All Letters not paid will be refused. Illustrated Price Lists forwarded on receipt of Six Postage Stamps.—GWYNNE AND Co., Hydraulic and Mechanical Engineers, Essex-wharf, Strand, London.

For Exportation.—The above can be obtained throug British Merchants, Shippers, and Colonial Agents.

Now Ready,

EVENINGS AT THE MICROSCOPE. By PHILIP HENRY GOSSE, F.R.S. Post 8vo., cloth. With numerous Engravings. Price Eight Shillings.

In this work the Author has described in familiar, but at the same time accurate language, the form, structure, and appearance of a large number of objects fit for Microscopic study, taken from the whole range of the Animal world. Many notes are interspersed on the use of accessory instruments, on manipulation, and on the preparation of specimens; and the whole forms a fit Introduction to Microscopic Zoology.

The observations are almost entirely original, and they are copiously illustrated by Engravings, mostly drawn upon wood, *direct from the life*, by the Author himself.

CHIEF ENGINEER—R. B. Longridge.

SECRETARY—Jonathan Cox.

This Company has been established to supply a recognised want existing in an important section of the mercantile community, by applying the principles of insurance, combined with efficient inspection, to steam boilers.

The numerous explosions of steam boilers that have taken place during the last four years have proved the necessity of scientific supervision, which if not voluntarily adopted by the employers of steam power, will doubtless be eventually forced upon them by Government interference.

It being evidently the interest of the Company to prevent accidents to the boilers insured by them, they have been careful to select the highest engineering talent, and such as is known to be specially valuable in this particular department of the profession. Should such accidents, however, unfortunately occur, the insured will not suffer pecuniary loss in addition to other inconvenience.

The Company appeal confidently for the support of all employers of steam boilers, not only on the ground of the wisdom and prudence that induce the careful manufacturer to insure his property generally, but on the still higher one of assisting in the prevention of the fearful sacrifices of human life that are almost sure to be consequent upon accidents of this nature.

The Company insure boilers of every description, and also any damage arising to buildings and property from their explosion; exclusive, however, of fire risks, and destruction of ships by marine boiler explosions.

They also assure the lives of workmen and others to a limited amount per head.

Where boilers sustain injury from accidental causes, though explosions may not actually ensue, the damage will be made good, or the amount thereof paid, by the Assurance Company, according to valuation.

The owners of boilers who may not wish to insure their full value, are at liberty to take policies for not less than £100 on each separate boiler, thus securing inspection and an assurance of £100 on each boiler, at a premium varying from 15s. upwards.

A "Registration of Steam Boilers" has also been established, on the principle adopted at Lloyd's in the case of ships. New boilers are examined and tested by the officers of the Company previous to leaving the works of the makers, and certificates issued according to their classification.

The Inspectors will, if required, indicate the engines of the insured, and advice will be given by the chief engineer of the Company in all matters relating to the economical use of steam power.

LIFE.

Enginemen, Stokers, and all persons attendant upon Boilers or Engines.—To insure £100 on each life lost by boiler explosion, £1 per annum, inclusive of Government duty.

Workpeople employed in mills or works generally (exclusive of those above specified).—To insure £50 on each life lost by boiler explosion, one shilling per head per annum on the whole number employed in such mills or works, inclusive of Government duty.

Cases of extra risk taken at increased premiums.

BUILDINGS AND OTHER PROPERTY.

Buildings, machinery, &c., are insured against damage from boiler explosions, at specific rates, from 1s. to 7s. per cent., according to Surveyor's report.

By order,
J. COX, Secretary. (174)

WEBSTER'S METHOD OF RIGGING SHIPS.

A correspondent sends us the following:—

Belfast, 11th Feb., 1859.

GENTLEMEN,—If some knowledge of mechanics without any of seamanship may entitle me to form an opinion, I regard Mr. Webster's proposed method of rigging ships, described in your number of 7th Jan., 1859, as a valuable improvement. Its most important feature, if I understand the description, is making the masts in one piece for the entire height, so that the yard may be lowered to the level of the deck when required. This arrangment must be especially advantageous in such vessels as our new "screw ships of the line," which are intended by their builders to be at once full-rigged sailing ships and full-powered steamers; for it is well known that when a vessel is steaming in a calm or against the wind, the resistance of the air against the rigging is a serious drawback to her speed; and Mr. Webster's plan of lowering the yards will reduce this to a minimum. His "retractile" bowsprit, to borrow a term from zoology, will be advantageous for the same purpose; for a bowsprit is, of course, useful to a sailing vessel by enabling her to spread more canvass, but is an encumbrance to a steamer in a head wind. The difficulty you point out, of obtaining sound sticks of timber of the requisite length, may be easily obviated by substituting iron for wood, as iron masts may be made of any length in one piece. Indeed, the introduction of iron masts must inevitably lead to the disuse of round-tops and all such "top hamper." The union of sail-power and steam-power in the same vessel, without placing the other under any disadvantage, is a most important object, both for ships of war and for the Australian trade, and I am inclined to think has not yet been attained. The *Royal Charter*, which is a screw clipper, appears in no way inferior to the best clippers without screws. Mr. Webster's invention will also be useful in enabling the rigging to be worked from the deck; a most desirable object, not only for the purpose of saving labour, but also of diminishing danger to life. It is intended to work the rigging of the *Great Eastern* from the deck, and by steam-power. I have met with no detailed account of the way in which this is to be done; but I think that very probably there is nothing in Mr. Webster's invention, except the "retractile" bowsprit, but what has been anticipated by the designers of the *Great Eastern*.—Respectfully yours, J. J. M.

METAL AND COAL TRADES, &c.

[FROM OUR OWN CORRESPONDENT.]

Iron and Coal Trades of the Country generally—Those of South Staffordshire—Combined opposition of Traders to the Great Western Bill—Iron and Coal in Derby, Lancashire, and Yorkshire—Glasgow Iron Trade: Great Decrease of Exports—The Hardware Trades of Birmingham and Wolverhampton—The Labour Market; The Glass Makers; The Halifax Stone-Masons—Sheffield, Rotherham, and Hackenthorpe Trades—Northumberland and Durham Districts—Ravensworth and West Hartley Coals for Steam Purposes—Coal Trade of the Tyne—South Yorkshire Coal Trade—Coal Trade and Colliers of South Staffordshire.

THE iron and coal trades of the country generally may be reported this week as having prospects of a more cheering character than those which were before them at the time of our last. It cannot be stated that any large accession of orders has taken place in the week, yet, as the probabilities of a prolongation of peace are more than at the time of our last reports, there is more cheerfulness on every hand, with a consequent firmness or slight upward tendency of rates for both pig and manufactured iron.

From South Staffordshire we learn that the orders from the United States continue steady, and that there is a good demand for railway iron. The bulk of the latter description of orders, however, it is said go to South Wales, on account of the greater facilities there for the production of that class of merchant iron. Good hot-blast mine pigs of native make are not so easy this week, and the slackness of poor descriptions is not so conspicuous.

The iron and coal masters and the traders generally of South Staffordshire and Birmingham are uniting with other districts in a vigorous opposition against a bill which the Great Western Railway Company are bringing into Parliament to increase their carrying rates, and to obtain other powers as carriers which in several instances will more than double the present cost of conveying merchandise upon the greater portion of that line. The matter is regarded as of serious import in Birmingham and its surrounding district.

Of the wide district embracing Derby, Lancashire, and York, the demand for railway iron work during the week has been good, and there have been frequent inquiries for bars and plates. The rates are well maintained. The demand for Derbyshire pig iron is on the increase amongst local ironmasters, and a much larger quantity of the Northamptonshire ores now continues to be received. The coal trade is not so brisk as during the corresponding month of last year, but the remarkable mildness of the weather has materially diminished the consumption for household purposes.

In the Glasgow market on Tuesday last, the shipments of the week were reported at only 1,283 tons, whilst those of the corresponding week last year amounted to 10,034 tons, leaving a falling off of 8,751 tons. The rates realised on Tuesday were, for No. 1, 51s. to 51s. 3d; Mixed Nos., warrants, 51s. 5d. to 51s. 7d.; Mixed Nos., maker's iron, 51s. to 51s. 3d; Nos. 3, 51s. to 51s. 3d. Market drooping.

The Birmingham and Wolverhampton trades continue as a whole quiet, without (except in rare instances) either great activity on the one hand or marked depression on the other. The orders are pretty evenly divided between the home and foreign markets—India and the United States towering high above any other foreign customer, and the northern counties being the leading representatives of the British requirements.

The labour market does not seem to be overstocked either in this particular district or in any other part of the kingdom.

Having received overtures from some of the men, the master glass-makers have offered to re-open their works upon the men complying with certain conditions in respect of the objectionable rules.

The dispute between the stone-masons of Halifax and their masters has been settled, and the men have resumed work.

In Sheffield, the pacific tone which has pervaded the continental imports during the week, has produced a decidedly favourable effect; nevertheless, whilst some houses are tolerably well to do, many others could do more than they have now the profitable opportunity of doing. American advices are most encouraging, without, however, many orders yet, either for rolled steel or cutlery. The employment on continental account is partial; and there is only little doing in the home trade. That stocks are low in the country is shown by the urgency of the orders when they are received, as well for plated as for steel wares.

At Rotherham, trade is by no means active.

At Hackenthorpe and its neighbourhood, the sickle-makers are upon strike.

In the Northumberland and Durham district pig-iron continues to rule low, and the coal trade is quiet. The coking trade, too, is getting quiet. How far this last-named feature of the trade has been brought about by the diminished use of coke upon the railways consequent upon the adoption of coal-burning principle to locomotives, remains to be proved.

Ravensworth West Hartley coals have been tested by the French Government at Cherbourg, for their steam generating qualities; and the experiments have been so far successful, that the Comte de Maricourt, the French Consul at Newcastle-upon-Tyne, has notified to the parties interested, that his Government has included the West Hartley amongst the steam coals to be supplied to the French navies.

The most important recent event in the history of the coal trade of the Tyne, is the opening of the Tyne Docks by the North Eastern Railway Company. These docks are capable of shipping 1,600,000 tons of coal in the year, and may be made, by the extension of jetties, to ship 4,000,000 tons. To enable the Tyne colliers to compete effectively with the Yorkshire and Midland men great dispatch is being used. On the day of the opening of the Tyne Docks, a screw steamer was put under one of the spouts, received 400 tons, was trimmed, and ready for sea, in fifty-five minutes. Under proper arrangements, two such steamers can be loaded at one spout in the same tide.

Dulness pervades the South Yorkshire coal trade.

The colliers of South Staffordshire have commenced to subscribe a shilling each towards the expenses which will be entailed by their application to Parliament, with their Yorkshire brethren, for a short-hours' bill. The coal trade in that district cannot be considered buoyant. The supply continues more than equal to the demand.

LIST OF MISCELLANEOUS TENDERS INVITED, AND ENGAGEMENTS OPEN.

The tenders and vacancies which appear in this weekly list are not repeated in succeeding numbers.

PIER AND OTHER WORKS, *Elie Harbour, Fifeshire.*—Plans, &c., Mr. C Elie. Tenders with Mr. Jamieson, at Elie-house; or, Mr. Andrew Wilkie, banker, Leven, March 19.

DRAINAGE WORKS and IRON PIPES.—The Commissioners of Police of Burgh of Portobello ask tenders for sewerage works, also for 243 yards of cast iron pipes. Plans, &c., Commissioners' offices, Council Chambers, Portobello. Schedules of Measurement, &c., Mr. Paterson, C. E., Surveyor, 20 St. Andrew-square, Edinburgh. Tenders, noon, March 14.

WHARF OR QUAY, *Middlesbro.*—For Stockton and Darlington Railway Company. Plans, &c., Northgate, Darlington. Tenders, March 24, Mr. Mac Nay, Sec., Darlington.

LIMEWORKS, *Direct Portsmouth Railway.*—Tenders from limeburners and others, on the Portsmouth Direct Railway, at Buriton. John Mariner, or Luke Gumbrill, at Buriton, will show the ground. Tenders, March 31, to Messrs. Dunn, Hopkins, Blakemore and Co., Alresford; and Mr. W. Adams.

SEWERS, *Dundee.*—Plans, &c., Mr. John Fulton, to surveyor, Police-buildings. Tenders to Commissioners of Police, March 28.

LOWERING HILL, &c.—London and Hugbridge Turnpike Road, Chiddleton Heath, near Leek. Plans, &c., Mr. Leach, surveyor, Wall-hill, Leek. Tenders, March 17, to Messrs. Challinor and Co., Leek.

ROADS, *Tynemouth.*—Repair and maintenance of public highways. Specifications, &c., Boro' Surveyor's Offices, 40 Norfolk-street, North Shields. Tenders, March 16, Town Clerk, Tynemouth.

STREETS, *Luton.*—Paving, Channelling, &c. Plans, &c., Surveyor's Offices, 15 Stuart-street, Luton. Tenders, March 15.

ROADS AND REMOVAL OF SCRAPINGS, *St. Mary, Islington*—Forms, &c., of Mr. Layton, Vestry Clerk, 21 Milner square. Tenders, March 16.

CONVERSION, *Hanley.*—Pheonix Foundry into an Earthenware Manufactory, &c. Plans, &c., Messrs. Ward and Son, Architects, or Messrs. Meakin, Hanley. Tenders to Messrs. Meakin. No date.

CHURCH, *Bolton-on-Swale.*—Restoration, &c. Drawings to the 14th, at Rev. A. Cumby's, Scorton, near Catterick. Quantities of the architect, Mr. G. Fowler Jones, 4 Newstreet, York. March 16.

BANK, *Worcester.*—New premises for City and County Banking Company. Plans at Rectory House, St. Nicholas, Worcester. Particulars, Mr. E. W. Emslie, architect, March 28.

VILLAS, *Picklebridge, near Halifax.*—Masons', carpenters', joiners', plumbers' and glaziers', plasterers', slaters', and painters' works of two villas. Plans, Messrs. Dobson and Charley, architects, Park-row, Leeds. March 18.

HOUSES, *Worcester.*—Conversion of a building in the Moors into three dwelling-houses. Plans, &c., Mr. E. L. Pugh, solicitor, 81 High-street, Worcester. No date given.

SCHOOLS, *Spilsby and Hundleby, Lincolnshire.*—Schoolmaster's house and school-rooms. Plans, &c., Rev. Mr. Turner, incumbent, Spilsby. March 16.

SCHOOLS, *Tinterden.*—Infant school and class room to boys' school. Plans, &c., Mr. Scratton, solicitor, Tinterden; particulars, Mr. Pope, architect, 21 Bedford-row, London. March 15.

RECTORY HOUSE, *Shrewsbury.*—At Yockleton, parish of Westbury. Plans and tenders to Mr. Cranston, architect, 2 Bennett's-hill, Birmingham, to March 26.

ADDITIONS, *Buxton.*—Hall and Shakspere Hotels. Plans, &c., Buxton Estate office. Tenders, E. W. Wilmot, Esq. Buxton, March 16.

NEWSROOM, SHOPS, &c., *Rochdale.*—Plans, &c., Messrs. Starkey and Cuffey, 40 Princess-street, Manchester. Tenders, Rochdale Market Trustees, April 2.

RE-BUILDING PREMISES, *London.*—No. 28 Addle-street, City. Drawings, &c., to March 15; particulars, Mr. R. Parris, architect, 5 Walsingham-place, Lambeth.

PIG-IRON, *Navy.*—Soft-melting. Distribution of iron and forms of tender, at Storekeeper General's office, Somerset-place. Tenders to two, March 22.

HAND STONES, *Navy.*—Portland stones for scrubbing ships' decks. Samples and tenders as next above.

TAR, PITCH, AND TALLOW, *Navy.*—Descriptions and tenders as above.

OIL, *Dublin.*—125 tuns of best rapeseed, for lighthouses. Proposals to March 23, to Mr. Wm. Lees, secretary, Ballast office, Dublin.

DESIGNS FOR A WORKHOUSE, *Sheffield.*—Near Penistone. Cost not under £2,500, of local stone. Particulars, Clerk of the Guardians, Penistone. Plans, March 16.

DESIGNS FOR NEW SCHOOL OF ART, *Coventry.*—The second prize, £10 10s. Particulars, R. Caldicott, jun., Hon. Sec. April 9.

PLANS FOR POLICE STATION, *Birmingham.*—Lady Woodroad. Time extended to March 28; plans to Town Clerk.

MANAGER OF GAS WORKS, *Scotland.*—Salary to commence at £350 per annum. Printed applications and testimonials to Mr. F. Lyon, Edinburgh, and Leith Gas-Light Company, April 9.

AS SURVEYOR FOR HANLEY.—Whole time. £170 per annum. March 21. Mr. E. Challinor, Town Clerk, Hanley.

AS FLOUR-MILL ENGINEER.—Taking the entire charge of an engine, and knowing the general work of a flour-mill. —A 151, *Manchester Guardian.*

MECHANICAL DRAUGHTSMAN.—For Italy. Acquainted with steam engines, mill-machinery, &c. Age 25 to 30. Salary, £2 to £2 10s. "W.," Mr. Lidstone, George-street, Plymouth.

BRICKMAKING.—A contractor to make and burn bricks. Address, No. 118, *North British Advertiser* office, Glasgow.

AS ENGINEER.—In a large brewery, to conduct the engineering department. A thorough knowledge of machinery as well as the arrangement and erection of saw mills. Salary liberal. Address, under cover, to "Alpha," care of Messrs. Hunt and Stephenson, 4 Parliament-street, Westminster, London.

ARTIFICERS' WORK, *War Department.*—From May 1, 1859, to March 31, 1862, at various barracks, &c. Applications for forms of tenders to be accompanied with guarantee of fitness. Information of the Royal Engineer, up to March 24, for 5s. Tenders to Director of Contracts, War Department, Pall Mall, March 31.

These Pumps are free from that liability to choke which is common to other Pumps, and their Working Parts are not susceptible of derangemen either from wear or from being long out of use. They pass entirely through them, with ease, any substance that may enter the Suction Pipes. The Novelties in these Pumps are their adaptation to the varied duties of Ships' Pumps; the facilities they afford for Cleansing the Suction Pipes, and for Sounding or Examining the Valves; the readiness with which they may be used for Ventilating the Bilge, or for acting as a Syphon either for Watering the Ship, or for extinguishing Accidental Fires on board; the rapidity with which they can be converted into Fire Pumps, or be applied to th Washing of Decks; and their capability of Pumping from Several Compartments.

T. SUFFIELD AND CO.

Also respectfully solicit the attention of STEAM SHIP BUILDERS and OWNERS to their Large and Varied STOCK of

ASSORTED STORES FOR MARINE PURPOSES.

They keep a Large Stock of Goods, of their own Manufacture and from the Best Makers, constantly on view; so that by a visit to their Works or Depôt, much valuable time may be saved by Managers, Engineers, and other Gentlemen who may require such Stores, together with a further saving in the cost of such Articles.

PATENT WEDGE and GROOVED SURFACE FRICTIONAL GEARING.—The PATENT FRICTIONAL GEARING COMPANY, Proprietors of ROBERTSON'S WEDGE SURFACE FRICTIONAL GEARING PATENTS, grant Licences to Users of Machinery, for the unlimited use of the System in their Works, on very moderate terms, enabling them to make or order from any Mechanician the Machinery they require.

The Company possess Five Patents relating to this Frictional System, including (in addition to their Bevel and Mitre Wheels) a System of Disc Clutches and Clutch Movements, Wheel Clutching, Reversing, Differential, Speed Ring, Varying Speed, and Break Movements, and of Shafting, Pillow Blocks, Shafting Hangers, &c.

Frictional Wheels thus formed are applicable to the heaviest as well as the lightest kind of work, and, in addition to their being extensively in use for ordinary gearing purposes, have been in use for a considerable time applied to Mills for Rolling Iron, the Screw-Propeller, Incline-Winding Engines, Saw Mills, Pumping Engines, Flax Scutchers, Fan Blowers, Calico-Printing Machinery, Steam Winches, Cranes, Hoists, &c.

This system gives great facilities for simplifying Machines, and for mechanical combination, and has the advantage of being noiseless and cleanly, there being no oil or grease used on the wheels. Wheel Catalogues and Circulars, giving particulars, sent free by Post; also a list of manufacturing Agents, and information regarding those who, from locality or experience, are best able to execute orders for the description of work required.

Office, 20 Buchanan Street, Glasgow. (146)

FIRE BRICKS.—THE FARNHAM INDESTRUCTIBLE SILICIOUS FIRE BRICKS have been greatly REDUCED in PRICE, and will be delivered at the Nine Elms Station, London, at 90s. per 1,000.—Address, G. H. OGSTON, J. M., Paine's Silica Works, Farnham, Surrey. (35)

SCOTT'S
PATENT GRASS SEED SEPARATOR,

which entirely extracts the Seeds of "COUCH," "TWITCH," "SPEAR," or "HAIR" GRASS and other impurities from

PERENNIAL AND ITALIAN RYE-GRASS, &c.,

AND

SCOTT'S PATENT CARROT SEED BEARDING

AND

CLOVER AND TREFOIL MILLING OR DRAWING MACHINE,

which effectually removes the beard from Carrot Seed, rendering it fit for sowing with facility by drill or otherwise, and by the separation of abortive or diseased grains vastly increases its vegetative per centage. By a slight modification it is applicable to the other purposes before mentioned.

These Machines were admittedly the most novel, and, at the same time, the most useful and important to the Farmer of any exhibited at the late SMITHFIELD CLUB SHOW.

They may be seen at work at the Establishment of the Manufacturer,

Mr. T. MIDDLETON, Engineer, Southwark.

Communications to be sent to the Patentee, J. SCOTT, 111 Drummond Street, Euston Square, London, N.W. (48.)

CLAYTON, SHUTTLEWORTH, AND CO.,

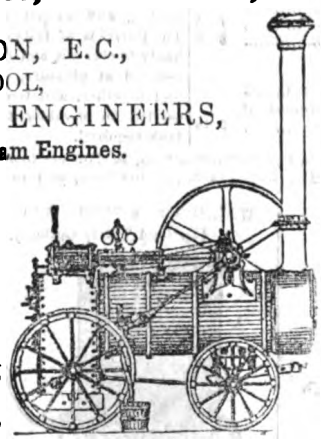
OF LINCOLN,

78 LOMBARD STREET, LONDON, E.C.,

AND 36 DALE STREET, LIVERPOOL,

AGRICULTURAL AND GENERAL ENGINEERS,

And Manufacturers of Portable and Fixed Steam Engines.



Combined Threshing Machines, which dress the corn ready for market at one operation. Grinding Mills, Saw Benches, Pumps for Irrigation and Mining purposes, with all necessary gearing for being driven by steam power. Full particulars and estimates given on application to the above address.

C. S. and Co.'s PORTABLE STEAM ENGINES are adapted for every purpose to which steam-power can be applied. When intended for winding, they are fitted with reversible link motion and winding gear. They are easy of removal, as may be seen by the engraving, and can be set to work immediately on arrival.

C. S. and Co. are now doing an extensive foreign and colonial business, and are prepared to send off engines and machinery of the before-mentioned kinds in a few days from the date of order. They would also call attention to the important *reduction in prices* made for the new year.

For Exportation.—The above can be obtained through British Merchants, Shippers, and Colonial Agents. (23)

FOWLER'S PATENT STEAM PLOUGH.

This Implement obtained

THE FIVE HUNDRED POUNDS PRIZE

AT THE ROYAL AGRICULTURAL SOCIETY'S SHOW, JULY, 1858, AT CHESTER,

(AFTER THREE YEARS' COMPETITION,)

And has also obtained

THREE HUNDRED AND SEVENTY FIVE POUNDS AT VARIOUS OTHER AGRICULTURAL SHOWS IN THE UNITED KINGDOM.

THE WINDLASS CAN BE FITTED TO ANY AGRICULTURAL ENGINE.

Goswell Road, London, E.C. (85)

IMPORTANT TO MANUFACTURERS, MILL OWNERS, &c.

GUTTA PERCHA MILL BANDS.

THE GUTTA PERCHA COMPANY beg to state that the increasing demand for the Gutta Percha Strapping for Driving-bands, Lathe-straps, &c., fully justifies the strong recommendations they have everywhere received.

Their durability and strength—permanent contractability and uniformity of substance—their non-susceptibility of injury from contact with oils, grease, acids, alkalies, or water—and the facility with which the only joint required can be made in bands of from 200 to 300 feet long—render them superior to leather for almost all working purposes, and decidedly more economical.

TESTIMONIALS.

IMPORTANT ANNUAL SAVING.

From TRUMAN, HANBURY, BUXTON, & Co., Brewery, London.

"In reply to your inquiry, we have much pleasure in bearing our testimony to the advantages, both as regards economy and saving of time, effected by the use of your Patent Gutta Percha Bands in lieu of Leather Straps. The stoppage of one portion of our works through the failing of the leather strap used to be of daily occurrence—but with this annoyance we are now never troubled. We have had these straps in operation for nearly three years, and are assured by our Engineer that *they effect a saving to us of at least* THIRTY POUNDS *a year.*"
